**Acerca de este libro**

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

**Normas de uso**

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

**Acerca de la Búsqueda de libros de Google**

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

**Usage guidelines**

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

**About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 30, 1905.

THE

# ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

## VOL. XXXV. (NEW SERIES.)

FROM JANUARY 6, 1905, TO JUNE 30, 1905.

LONDON:

Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1905.

Digitized by Google

# INDEX TO VOL. XXXV. (New Series.)

**NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes and Business Notes, references to which are shown by light type (thus, 290).**

## A.

Acceleration Tests of Electric and Steam Locomotives, 723
Accidents, 111, 462, 463, 469, 498, 606, 642, 714, 785, 786, 893, 901, 924; also see Tramway Cases in "Legal Intelligence"
Accidents, Reporting, in connection with Electric Lighting, 741

**Accumulators, etc.:**
Acid for, 599
Bijour Storage Battery, The, 669
Dry Battery Litigation, 716
at Electricity Works, see under name
Questions and Answers, see QUESTIONS, ETC.
for Traction, 441
Unit, The, 543

Adams, W. P., Dust Destructors and Electricity Works, 88
Addenbrooke, G. L., The Value of Overhead Mains for Electric Distribution in the United Kingdom, 335
Addresses, New, Change of, see "Removals"
Administrative County of London and District Electric Power Bill, etc., 411, 416, 444, 481, 519, 701, 738, 742, 757, 823, 896, 901; also see POWER TRANSMISSION
Advertising, Value of, 759, 902
Agencies, 68, 320, 464, 681, 823, 894, 925
Allen, A., Heating by Electricity, 881
Alternating and Direct Current Circuits, Relays for, 621
Alternating-Current Motors in Industrial Service, P. D. Ionides, 884
Alternating-Current Rectifying Effect, 40
Alternating-Current Series Motor, The, F. Creedy, 589, 617, 633, 673, 843, 879, 917
Alternators, see DYNAMOS, ETC.
Aluminium, 128, 164, 199, 234, 272, 326, 533, 796
American Electric Blue Printing Machines, F. C. Perkins, 596
American Electrical Exports, 290
American Visit of the Institution of Electrical Engineers, Dr. Morris, 160
Amsterdam-Haarlem Electric Railway, 11
Anderson, A. C., Application of Electricity to Mines, 303, 336
Application of Electricity to Industrial Purposes, J. F. C. Snell, 446, 478, 707
Application of Electricity to Mines, A. C. Anderson, 303, 336
Appointments, see "Personal"
Appointments Vacant, see each Issue

**Arc Lamps:**
Angold, The, 93
Brockie-Pell, The, 433
Excello, The, 175, 457
Flame, 237
Improvements in, 543
Maxim, The, 32
Meridian, The, 484
Street Lighting by, H. B. Maxwell, 87, 275
Street Lighting by, S. E. Fedden, 853, 889

Arc, The Metallic, I. Ladoff, 623
Arc Works Sports, 883
Armatures, see DYNAMOS, ETC.
Arnheim Party-Line Telephone System, 517
Atkinson, L. B., and C. J. Beaver, Some Points on the Selection of Electric Cables, 204
Australia, Printed Matter for, 177
Automatic Regulators, Operating Device for, 373
Automatic Signalling on the Underground, 226
Automobiles, 30, 31, 75, 162, 168, 174, 182, 217, 241, 246, 247, 289, 291, 342, 390, 362, 406, 427, 441, 505, 570, 714
Auxiliary Railway Signalling, 263, 415
Awards, 211, 321, 397

## B.

Bache, W. J., Gloucester Electricity Works, 798, 847
Bailie, J. D., Condensing Arrangements in Central Stations, 110

**Balance-Sheets, etc.:**
Blackpool Accounts, 888
Burnley Tramway Accounts, 816
Bury Accounts, 888
Colchester Accounts, 888
Hanley Accounts, 539
Huddersfield Accounts, 521
Launceston (Tasmania) Accounts, 854
Liverpool Tramways, 519

**Balance-Sheets, etc.** (*continued*):
Sheffield Public Lighting, S. E. Fedden, 853, 889
Shipley Accounts, 816
South Shields Accounts, 888
Stepney Accounts, 672
Walsall Accounts, 278

Ballads of Business, 420
Barton, E. C., Some Notes on High-Speed Feed Pumps and the Reasons for their Inefficiency, 56
Beaver, C. J., and L. B. Atkinson, Some Points on the Selection of Electric Cables, 204
Belt Creep, 901
Bennett, A. R., Telephone Trunk-Line Charges, 158
Bennett, A. R., The Proposed Telephone Deal, 24
Berlin-Zossen Tests and their Results, Dr. Schulz, 767
Blisset, P. T., Notes on the Running of a Private Lighting and Power Plant, 267, 308
Blue Printing Machine, Electrical, F. C. Perkins, 596
Board of Trade Electric Lighting, etc., Regulations, 685, 744
Board of Trade Reorganisation, 398, 794

**Boilers:**
Babcock and Wilcox, The, 168
at Clyde Power Company's Works, 870
at Electricity Works, see under name of Station
for Hong Kong Tramways, 44
in St. Louis Union Station, 547
Stirling, The, 68
Watertube, 253

Booth, W. H., and J. B. C. Kershaw, Fuel Economy in Steam-Power Plants, 165, 275

No. 1, Vol. XXXV. LONDON, JANUARY 6, 1905. PRICE 3D.

## NOTES.

**Faraday Society.**—We regret that in the report of this society's proceedings, which appeared in our last issue, the name of Mr. L. Gaster should have been inadvertently rendered as "Mr. L. Gasta."

**Municipal and County Club.**—At the next house dinner on the 27th inst., Sir William J. Collins, M.D., D.L., J.P., chairman of the Education Committee, London County Council, will be the guest of the club.

**New Publications.**—"Catalogo da Biblioteca du Marina," two vols. (Rio de Janeiro Government Printer). The library of the navy department of Brazil is a highly technical one, and is arranged on the decimal system of Melvil Devoy by Captain-Lieutenant J. A. dos Santos Porto. There is a subject index and an author's index, the former containing 928 pages.

**Personal.**—We are pleased to hear that Mr. Gisbert Kapp has recently been made an honorary member of the Physical Society of Frankfort. This honour shows that Mr. Kapp's work is as highly appreciated on the Continent as in this country, and it will afford him a pleasant reminder of his friends across the Channel when he returns to England to take up his appointment at Birmingham University.

**Electric Lighting Provisional Orders.**—Elsewhere in this issue will be found an official list of applications for electric lighting provisional orders for the next session of Parliament. The total number is 62, which is 14 less than in the last session. Looking through the list, we see that this year 32 municipal authorities are seeking electric lighting powers in the districts they control or in adjoining areas, and that there are 30 companies asking for powers. Last year 35 local authorities and 41 companies sought powers. The reduction in the number of applications is largely due to the fact that electric light and power services have already been organised in the most remunerative areas within the United Kingdom. Quite a large number of applications, both last year and this, come from power distribution companies who wish to supply small areas in bulk.

**Manufacturers and Contractors.**—The agreement between the Electrical Manufacturers' Association and the Electrical Contractors' Association has been terminated, the primary cause being the question of preferential discount. Formal notice was given by the first-named organisation in order that terms might be reconsidered, whereupon the contractors put forward counterclaims for amendment, they having for a long time alleged grievances against the manner in which manufacturers interpreted the clauses referring to preferential discount. The grievance of the contractors appears to be that discounts have been given to parties outside the legitimate trade, and the official organ of the contractors considers that the question of contractors being accorded the "favoured nations" clause should be a secondary consideration as compared with the exclusion of outsiders from participation in the preferential discount. We observe that negotiations are about to be opened with a view to a fresh compact, and we trust that an equitable solution will be arrived at, as it is eminently desirable that there should be concord between the two interests. To attain this end, it will be well if the parties first come to a distinct understanding as to who is entitled to trade discount.

**Personal.**—Mr. E. Kilburn Scott, A.M.I.C.E., M.I.E.E., has been appointed chief of the electrical engineering department at Sydney University. We understand that this is a new department, which he will have to organise and work. Mr. Kilburn Scott has for the past four years been a lecturer to the senior electrical engineering students at the Northampton Institute, Clerkenwell. In addition to his lecturing duties at Sydney, we understand that he will engage in consulting practice. His experience with Messrs. Johnson and Phillips and other firms included a considerable amount of power transmission work. It will be remembered that Mr. Kilburn Scott is the author of a treatise on "The Local Transmission of Power for Workshops," which we published some years ago. We wish him every success in Australia.

**Commercial Education in Japan.**—The perusal of an interesting little article on this subject in the *Journal* of the Society of Arts impresses one with the systematic manner in which the Island Empire of the East has, as in other fields, set to work to frame a curriculum of commercial education. There are practically three stages, culminating in the high schools at Tokyo and Kobé, which may be regarded as commercial universities. One of the leading features of the system is the excellent way in which the grades are consolidated, a student on completing one course being ripe for the next. The substance of the training consists of internal and external economics, technology, practical physics, general law, mathematics, and composition, with such foreign languages as English, German, French, Chinese, and Korean. Dai Nippon is certainly not lacking in culture, yet our allies do not consider it necessary to instil the classics into the youth intended for a commercial career, though it will be noticed that considerable attention is paid to the languages of countries with which he is likely to have dealings. For linguistic instruction the foundations at Tokyo and Kobé have several foreign professors, who in course of time will be replaced by natives, as was done in regard to electrical tuition, organised by Profs. Ayrton and Perry. In fact, this has been the Japanese policy in practically all spheres, including the public services. Japan does not disdain to borrow from the West. On the contrary, where she excels is in selecting her instructors from the most capable, and in adopting the best features of their civilisation, while rejecting the bad or the indifferent.

**Inventors' Rights.**—An important judgment was delivered by Mr. Justice Buckley the other day concerning the relations between employer and employé in reference to patents. The litigation arose out of a machine to gin cotton without injuring the fibre, but the legal aspect of

Digitized by Google

the case is of general application. A patent was obtained by the plaintiff, and while the machine was under construction certain variations were made, for which the defendant, who had just before been engaged by plaintiff as an engineering draughtsman, appears to have contributed a few trifling suggestions. These alterations were made the subject of a supplementary patent. Shortly afterwards the plaintiff summarily ended his association with the defendant. A day or two later the defendant filed an application on his own behalf, the specification for which was almost a facsimile copy of that lodged by the plaintiff in connection with his supplementary patent. His Lordship, in revoking the patent which had been granted to defendant through the oversight of the plaintiff's agents in not depositing an objection within the allotted time, cited the following words from the judgment of Mr. Justice Earle in Allen *v.* Rawson: "I take the law to be that if a person has discovered an improved principle, and employs engineers, agents, or other persons to assist him in carrying out that principle, and they in the course of experiments arising from that employment make valuable discoveries accessory to the main principle and tending to carry that out in a better manner, such improvements are the property of the inventor of the original improved principle, and may be embodied in his patent; and if so embodied the patent is not avoided by evidence that the agent or servant made the suggestion of the subordinate improvement of the primary and improved principle." It is reassuring to see that on this point law accords with equity.

**Electrolytic Formation of Carbon.**—In the *Zeitschrift anorg. Chemie*, Messrs. F. Haber and S. Tolloczko contribute an article upon the reduction to carbon of chemically-combined carbonic acid, of which an abstract appears in the *Journal* of the Chemical Society. Solid sodium hydroxide was fused in an iron dish; it was then cooled, and as soon as it solidified was electrolysed by a current of 0·15 ampere and 11 volts, and finally at 200deg. with one ampere and five volts. The yield of sodium was 39 to 46 per cent. Barium chloride was electrolysed at a temperature 400deg. below its melting point. When barium carbonate is added to barium chloride, carbon is formed at the cathode in quantitative amount. By aid of sodium, barium carbonate is readily converted into oxide, whilst carbon separates. Barium chloride and barium carbonate were fused together in a nickel crucible, allowed to cool, and then electrolysed at 550deg. to 600deg., the cathode consisting of iron, platinum, or graphite. Carbon separated in a dendritic form. The E.M.F. between 550deg. and 580deg. varied from 6 to 10·4 volts, whilst the current strength varied from 22 to $45 \times 10^{-3}$ amperes. In the experiments with graphite electrodes, the latter were not attacked. During the electrolysis of barium chloride in a Hempel furnace, carbon was formed at the cathode, owing probably to the action of carbon dioxide and oxygen present in the heating gases on barium chloride, a reaction which proceeds thus: $BaCl_2 + CO_2 + O = BaCO_3 + Cl_2 - 11{,}850$ cal. The analogous reaction with calcium chloride, proceeding according to the equation $CaCl_2 + CO_2 + O = CaCO_3 + Cl_2 + 1{,}550$ cal, was studied. Chlorine is also produced in an analogous manner by the action of carbon dioxide and oxygen on sodium chloride. No carbon was obtained when barium chloride was electrolysed in an electric furnace at about 600deg. in an atmosphere of nitrogen. For the formation of barium and nickel chlorides as products of the electrolysis of solid barium chloride with nickel anodes, a polarisation of 2·65 volts would be expected according to the equation $Ba + NiCl_2 = BaCl_2 + Ni + 122{,}400$ cal. The value of 1·9 volts was found corresponding with the free energy of formation of solid barium chloride and nickel from the reaction $2BaCl + NiCl_2 = 2BaCl_2 + Ni$; the reaction $Ba + BaCl_2 = 2BaCl + 34{,}600$ cal. corresponds with 0·7 volt. Determinations of the E.M.F. of two solid Daniell cells, $PbCl_2/AgCl$, agreed with the calculated value 0·519 volt.

**Cape Town.**—The report of this Corporation for the year ending Sept. 22, from which we gave some extracts as to electric lighting last week, contains a number of interesting items. In the new station in Dock-road there are two 750-kw. dynamos, driven by Ferranti engines of 1,000 h.p., the largest of their kind in Africa. The number of consumers of electric light has been multiplied by 37 since the opening of the system in 1895. Up till 1900 very few people took energy for power purposes, but on a special reduction for day current being introduced the number promptly rose, and up to February of last year the motors connected represented 1,375 b.h.p., the result of a steady increase from 200 b.h.p. since the reduction in charge. The plant is called upon to provide energy at night for street and private lighting equal to about 50,000 8-c.p. lamps, leaving a margin of some 20 per cent. on the peak load. The charges have undergone material reduction since 1897, and from 1900 energy has been supplied in the day at 4d. per unit, as against 8d. at night. Mr. W. F. Long, the city electrical engineer, anticipates that within the next few months the economy lately effected in operating costs will enable the Corporation to again reduce their tariff, at any rate for lighting, and also the maximum charge for power; but he does not think they will be able to get below 4d. for energy in the daytime just yet. A new type of lamp has been installed in the side streets, and the overhead wires for street-lighting have been superseded by cables from England of double the size, enabling arc lamps to be placed in all the principal streets. In the year ending September, 1903, the Council paid interest and sinking fund charges to the amount of £9,244, a sum of £5,921 was placed to depreciation, £5,362 was allotted for small extensions, whilst £3,404 went in relief of the general rate. We also observe that during the year the Corporation sanctioned extensions of the tramway lines owned by the Camps Bay and other companies. Altogether the pioneer municipal electric light undertakers of Africa well merit congratulation upon their progress.

**Municipal Wiring.**—The opposition of the National Electrical Contractors' Association to the clause in the London County Council's Bill seeking power for local authorities to execute wiring was referred to in our issue of June 10, when we felt constrained to concur with the arguments of the objectors. One invidious circumstance to which the clause is calculated to give rise is that it would devolve upon the municipal engineer to pass the work of his private competitors. At a recent meeting of the Law and Parliamentary Committee of the County Council a deputation was received from the Hampstead Borough Council in reference to this subject. At this meeting it was suggested on behalf of the Electrical Contractors' Association that what is now known as the "Ealing Clause" should be adopted. For the sake of reference we reproduce this: "(73) It shall be lawful for the council of any metropolitan borough being authorised to supply and supplying electrical energy to expend money through a contractor, but not otherwise, upon the wiring and fitting and supplying with wires, fittings, and apparatus, the premises of their consumers or prospective consumers, and to enter into and carry into effect agreements and arrangements with respect thereto, and to make such charges therefor, whether directly or otherwise, as they may think fit. Provided that nothing

Digitized by Google

in this section shall authorise the council of any borough themselves to fix upon any consumer's premises electric light fittings or electric wiring other than may be required to complete the service line between the corporation's supply mains and their own apparatus upon such consumer's premises. (74) Any such council of a metropolitan borough may borrow, in the same manner and subject to the same conditions as if such expenditure were for the purposes of the Electric Lighting Acts, 1882 and 1888, as amended by the London Government Act, 1899, such sums of money as may be required by such council for the purposes of this part of this Act." One of the Hampstead representatives, Mr. Alderman Pritchard, who is also barrister to the metropolitan borough councils, assented to this clause, subject to slight modification, but a few days later the County Council intimated that, after careful consideration, they were not prepared to alter their original clause. It therefore seems inevitable that the struggle of 1903, when the contractors' opposition prevailed, will be renewed, and with increased vigour. The *Electrical Contractor*, which is the official organ of the association, contains a rallying call to the industry, enumerating several large towns which the efforts of the organisation have preserved to the private contractor.

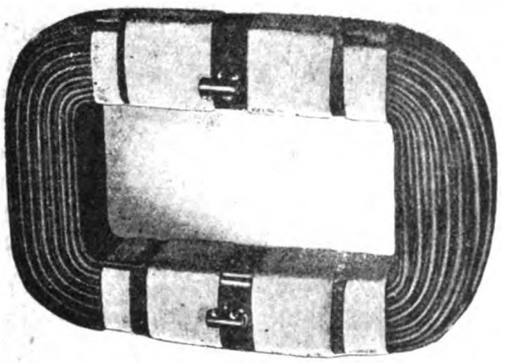
**Electricity from Tides.**—The vast amount of energy in the tides, which is at present unutilised, has attracted the attention of a large number of engineers. Unfortunately, the cost of the civil engineering works required to make this energy available for industrial purposes is, as a rule, prohibitive. Coupled with this high cost there are the variable high and low tide levels, and frequently the position in which the civil engineering works have to be constructed is such that their permanence is doubtful owing to the action of the waves. What is required to make tidal power available in large quantities can only be obtained economically under certain configurations of coast-line, The requisites are a large inlet which can be used to store water at high tide, and another large inlet which can be drained regularly at low tide, and from which the incoming tide can always be excluded. According to Mr. W. S. Cleveland, writing in the *Scientific American*, these conditions can be obtained in one or two localities in the United States and Canada. He describes these, and mentions as one of the best opportunities for applying this method of using tidal water power the harbour of the city of St. John, N.B. Kennebecasis and Courtney bays are large arms of the harbour, but both, under present conditions, are of little service to shipping. The entrance to the former bay is located above the famous Reversible Falls, but subject to the action of the tides at high water, and the latter is studded with dangerous reefs and rocky flats, which render it worthless to shipping, except at high water. The entrance to Kennebecasis Bay is very narrow, and the embankment making it serviceable as a high-water basin could be cheaply constructed; but the mouth of Courtney Bay is much wider, although not imposing any serious engineering difficulties in the work of converting it into a discharge basin. In applying the 30ft. head of water thus obtained, the narrow neck of land separating the bays could be crossed by power and tail-race channels, and the turbines located at the most convenient point thereon. Should previously suggested improvements, embodying the maintenance of continuous high water in this harbour, be carried out, a slight modification of the original plans would facilitate the application of this great water power, and make St. John City one of the leading industrial centres of the continent. As the author does not give any particulars of cost or area one cannot tell the horse-power available, or the capital charge per horse-power year, which is usually the prohibitive factor in these schemes. When, however, the indirect advantages from the large civil engineering works are such as are described above, there may be a chance of a remunerative undertaking being established.

**Californian Power Plant.**—A plant has recently been installed at Monterey, California, designed by the National Electric Company, of Milwaukee, which attracted a good deal of attention at the annual convention of the Pacific Coast Electric Transmission Association, and of which a description appears in the *Street Railway Review*. It consists of a 200-kw. generator and motor-generator set, comprising a synchronous revolving-field motor of 162 kw. capacity, which drives by direct coupling a National 550-volt direct-current railway generator with a rating of 150 kw. The 200-kw. alternating-current generator follows closely the structural design that has become well established in American types of revolving-field generators, and its inherent regulation is well within 6 per cent. at unity power factor. It is run at a speed of 600 revolutions per minute, and consequently, to deliver a current at 60 cycles, it is provided with 12 poles on its revolving field. The usual temperature guarantee, that with an atmospheric temperature of 25deg. C., the temperature of the machine will not rise more than 35deg. under a continuous 24-hour run at full normal load, was well above the limit reached in operation, the rise being but 22deg. above the temperature of the surrounding air. The efficiencies of the generator are as follows: 93 per cent. at 25 per cent. overload, 92·5 per cent. at full load, 91·25 at three-quarter load, and 88 per cent. at half load. The exciter runs at a speed of 1,450 revolutions per minute, is normally rated at 12 kw. at 110 volts, and is belt-driven from a pulley placed on the end of the generator shaft. The motor-generator set runs at a speed of 720 revolutions per minute, and in operation it has been found that the temperature of the synchronous motor does not exceed 25deg. C. above the temperature of the surrounding air, and the direct-current generator does not show a rise of more than 25deg. in any part when both machines are working under full-load conditions. An interesting feature in connection with the motor-generator set is that a 22in. pulley with a 16in. face has been placed on the shaft between the motor and generator, and belted to the flywheel of a 200-h.p. high-speed Buckeye engine. This gives absolute flexibility to the plant, in that during the hours of light load both the units of the motor-generator set may be run as generators, and in that the motor-generator set affords the link by means of which the railway load may be coupled in with the two-phase load, or *vice versâ*. Obviously, this enables a day alternating-current service to be maintained in conjunction with the railway load as minimum efficiency in operation, and though the installation of the motor-generator set may appear anomalous in view of the fact that the current for its operation is taken from generators located within the same premises, it is considered the rational solution of the problems presented by the local conditions.

**Insulation of Motor Field Coils.**—The *Street Railway Journal* contains an article upon some experiments carried out by the Deltabeston Fuse Company, of Providence, R.I., relative to the insulation and winding of their magnet wire for railway motor field coils. The experiments were conducted by the company with a view to the production of a field-coil insulation capable of withstanding unusual temperatures and practically impervious to water. The process involves the employment only of material which will not be affected by any ordinary motor temperature, and the material must be so treated as to render it waterproof. The portion of the coil upon which the terminals

Digitized by Google

are fixed is carefully insulated by covering with a single layer of a special asbestos paper. Over this and under the terminal a thin sheet of micanite is placed, upon which the terminal, after being soldered to the twine, is securely bound by asbestos twine, as shown in the accompanying illustration. The asbestos paper is then formed about the coil by damping it with a thin solution of good paste. It has been found desirable to cut the paper into various shapes in order to harmonise with the irregular form of the coil. Two layers are used in covering the body of the coil, the paper employed being about ·01in. thick, and it must be thoroughly impregnated with the paste. Before applying the second layer, the coil should be left overnight, and then placed in an oven for two or three hours, raising the temperature to about 300deg. F. Taking the coil out while hot, it should be immersed in a fairly thin solution of a paraffin insulating compound, allowing the coil to remain in same until thoroughly cooled down. The second jacket is similarly applied, and the coil having been air-dried, it is ready for a tight outer wrapping of ·03in. asbestos tape, preferably of about ¾in. width. Having been rapidly dried in an oven at 300deg. F., the coil is ready for its final dipping, which is performed by saturating it in a bath of good baking japan. The coil is



then allowed to drain, after which it is baked until quite hard, a period of three to four hours being required as a rule. To render the saturation perfect, the coil may be replaced in the japan bath, and having been again drained and baked the process is complete. The company's experience has shown that the repetition of this process twice a year, giving the motor one dipping and baking, is ample. To determine the value of this insulation, comparative tests were conducted under service conditions of coils as above and those wound on ordinary asbestos paper and cotton insulation, the exterior insulation in the latter being of the type commonly used throughout the States. At the end of a 97-hour practically continuous run the cotton-covered coil was reduced to charcoal, while the Deltabeston coil appeared to be quite uninjured. On the application of water the insulation of the cotton-covered coil receded practically to zero, the Deltabeston coil, on the other hand, exceeding the capacity of the instruments, some 400 megohms.

**Electrical Equipment of Canals.**—The report of Mr. S. E. Fedden, the general manager of Sheffield's electric supply department, upon his recent tour in America contains some interesting notes upon the electrical equipment of canals, which is largely the vogue on these waterways in Canada. Electricity is employed for illumination and for operating the various devices at the locks and the swing-bridges. Mr. Fedden gives a concise description of the Soulanges Canal—14 miles long—joining the St. Francis and St. Louis Lakes, which is typical of the system generally adopted. The canal banks are illuminated by 2,000-c.p. alternating arc lamps of the enclosed type, which are placed 480ft. apart on one side, and when nearing locks or bridges they are erected considerably nearer and on both banks, enabling navigation to be carried on with ease and safety during the night. Altogether, 219 arc lamps are used along the canal. The supply of energy is obtained from their own power-house, situated five miles from the Lake St. Francis entrance of the canal. At this point the Grease River crosses underneath the canal in a 10ft. culvert, and empties into the St. Lawrence. The water for the turbines is taken from the canal, the Grease River forming the tail race. The head of water obtained is about 20ft. The canal is crossed by seven bridges, which weigh about 100 tons each. The electrical apparatus for operating these bridges consists of a gear and friction mechanism driven by a 2-h.p. 220-volt three-phase induction motor, placed in a cabin at the centre of the bridge. By a simple movement of a lever in one direction the bridge can be started, or it can be stopped or retarded by a motion of the same lever in the opposite direction. A 3 h.p. induction motor is geared to a friction mechanism for operating the locks and sluice gates, which involves the same principle as that described for operating the bridges. The gates are closed or opened by means of a strut or drawbar hinged to the gate under the gate platform, at the end of which is a rack and pinion mechanism worked by the friction apparatus. The whole machinery is placed in a watertight cast-iron box, which projects about 15in. above the coping of the lock. At each lock there is a switch cabin, which contains two sets of transformers for stepping down from 2,200 to 220 volts, which is the motor voltage. One main switch controls all the motors at each lock. The electrical equipment of this canal, which has been in operation for over two years, has given entire satisfaction, and in concluding his observations Mr. Fedden pays this notable tribute to the system: "I think this is one of the best applications of electrical energy I have ever seen, the change to this system increasing the working capacity of the canals very greatly, besides effecting a large saving in manual labour."

**German Tramway Practice.**—*Kuhlow's Review* has an article upon the changes in German electric tramway practice during the past year. Few new lines have been installed, as experience has shown that with towns of less than 50,000 population a service cannot be conducted profitably, so attention has been mainly concentrated upon improvements in detail. A greater number of car miles are now run without increasing the track mileage, but how far the receipts have benefited is not stated. In most cases this increase in car mileage has been between 3 and 4 per cent., but on some of the large city lines it has reached 10 to 11 per cent. The type of car now favoured is of the single-truck order, with two motors and a short-circuiting brake, without an upper deck, but with movable windows, so as to have open cars in summer. Double-truck cars are not likely to be built frequently, because they are too large for German street conditions, and single-truck cars with trailers are cheaper and more flexible. Many trailers are being fitted with magnetic brakes to save extra brakesmen, and roller bearings have been found to effect a large saving in tractive effort. The G.E. 800 motor is being gradually displaced by motors of somewhat larger capacity. When replacing motor gearing a great deal of attention is now given to seeing that the motor pinion will have as long a life as the gear, which is generally made of ordinary cast iron, hardened steel being used for the pinion. A life of 24,000 miles for the pinion is considered satisfactory, though a few large companies have obtained 66,000 miles. A number of lines have placed wattmeters on their cars. These have been found to work accurately within 4 per cent. during four to six months' service, and have had an excellent influence on the current used by the motorman.

Digitized by Google

The single-tongue switch has gained a decided victory, maintenance cost being negligible compared with the double-tongue type. Contrary to American practice, the results with very large generating sets have not been of the best. Units of 1,000 h.p. to 1,500 h.p. have proved the most suitable for large stations, on account of economic conditions. Practically all the power stations are now equipped with storage batteries, which has resulted in substantial fuel economy, especially in small stations Feed-water heaters and purifiers have become almost universal, and the use of inferior fuels such as ashbin refuse with automatic firing has increased with good results. Liquid lubricants are displacing grease. Concrete is now recognised as the most desirable base for the track if the rails rest on an intervening layer of asphalt concrete 1in. thick, which must be allowed ample time to harden. The rails now coming into general use are much harder than the earlier ones. The Goldschmidt "thermit" process of welding has been applied successfully on some of the large systems, and the new Melaun method is well spoken of, though it is too early to pronounce definitely with regard to the latter. The fender is unpopular, and in some cities the authorities have prohibited it as more likely to increase than to diminish accidents. The tendency to reduce fares has undergone a reversal, especially on municipal lines. Transfer traffic has been encouraged, but more attention is being given to the control of transfers. There is also a tendency to sub-divide the management of operation by appointing inspectors of stopping places, switches, track-cleaning, etc. A valuable innovation has been the compilation of uniform statistics for all German street and light railways. The traction companies are making efforts with a view to the modification of the oppressive laws regulating liability for accidents. The executive offices of the Street Railway and Light Railway Association have been removed from Hamburg to Berlin, which is expected to facilitate management. Destructive competition between lines in the same area has given place to co-operation. There has been less controversy upon the question of municipal ownership. Some of the corporations have done well, but "quite a number" show deficits. It is gratifying to observe, however, that the officials of the two classes are working in harmony on all technical matters.

**Cooper Hewitt Converter.**—Patents have been granted in the United States to Mr. P. H. Thomas for three forms of the Cooper Hewitt converter or current rectifier. A description of these, with the accompanying diagrams, appears in the *Electrical World* of New York. It will be remembered that the converter is based upon the "electric valve" principle; a current passes through the converter in only one direction, an electrode resistance so great being opposed to flow in the opposite direction as practically to prohibit the passing of current of opposite character. The object of the new forms of rectifier is to provide means for conducting a large amount of current into and from the converter with relatively small resistance, to provide means for keeping the converter cool, and to withdraw from the chamber any excess vapour so as to maintain the vapour in proper condition. The enclosing chamber shown at the top of Fig. 1 is provided with two side tubular extensions containing columns of mercury, which constitute respectively the positive and negative terminals of the device. The lower ends of the tubes are open and are submerged in vessels containing mercury. The chamber is provided with a third tube in the middle, which terminates in a vessel also containing mercury. This vessel is connected by a pipe with a pump, the outlet of which is connected by a pipe with the bottom of one of the electrode vessels. In operation current is led into, say, the left-hand electrode vessel, then passes up the mercury column in the tube leading therefrom, then through the vapour in the upper chamber, and thence down through the right-hand column and to line by way of the circuit conductor. As more or less heat will be developed in the passage of the current, a more or less continuous flow of mercury is kept up through the left-hand tube into the chamber, whence it flows downward through the centre tube, carrying with it more or less of the gas or vapour contained within the chamber. This continuous flow of mercury will not only result in providing cool mercury for the positive terminal of the device,

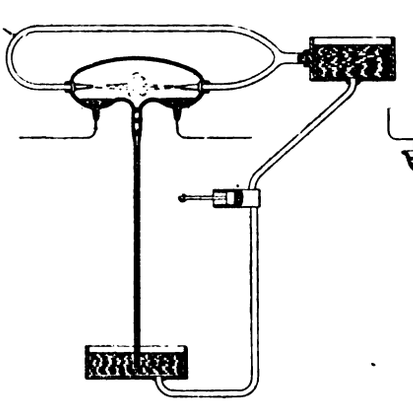


FIG. 1.

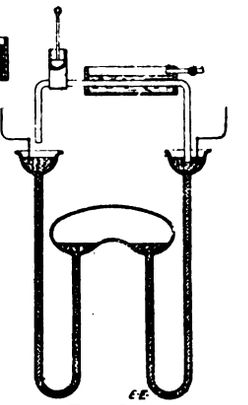

FIG. 2

but will continually act as a pump for maintaining the requisite purity with respect to the vapour in the chamber. The receptacle beneath the centre tube may be constructed to afford a considerable heat radiating surface, and there may be added a cooling pipe, as shown, for circulating water or other cooling fluid. It is generally found unnecessary to cool the negative terminal, as in some instances the device operates better while this terminal is hot. There will always be more or less condensation of the mercury vapour upon the walls of the vapour chamber, and the presence of the cold body of mercury contributes to this action, which results in keeping the vapour at its proper density. The second diagram

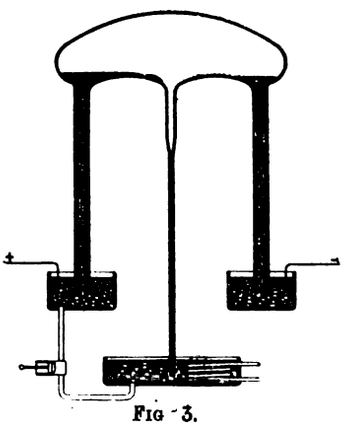

FIG. 3.

illustrates another arrangement, in which the lead wires are connected directly with the positive and negative terminals, and mercury from a receiver is forced through pipes into the chamber in the form of a finely-divided spray. By this means both the terminals and the conducting vapour within the chamber are cooled. Fig. 3 represents an arrangement for use when it is desired to maintain the conducting gas or vapour in the container at a high pressure, in which case atmospheric pressure might be insufficient for the purpose. The pressure within the container corresponds to the height above the level therein of the mercury in the tubes shown. In this case a water-jacket for cooling the mercury is shown around the pipe connected with the pumping arrangement.

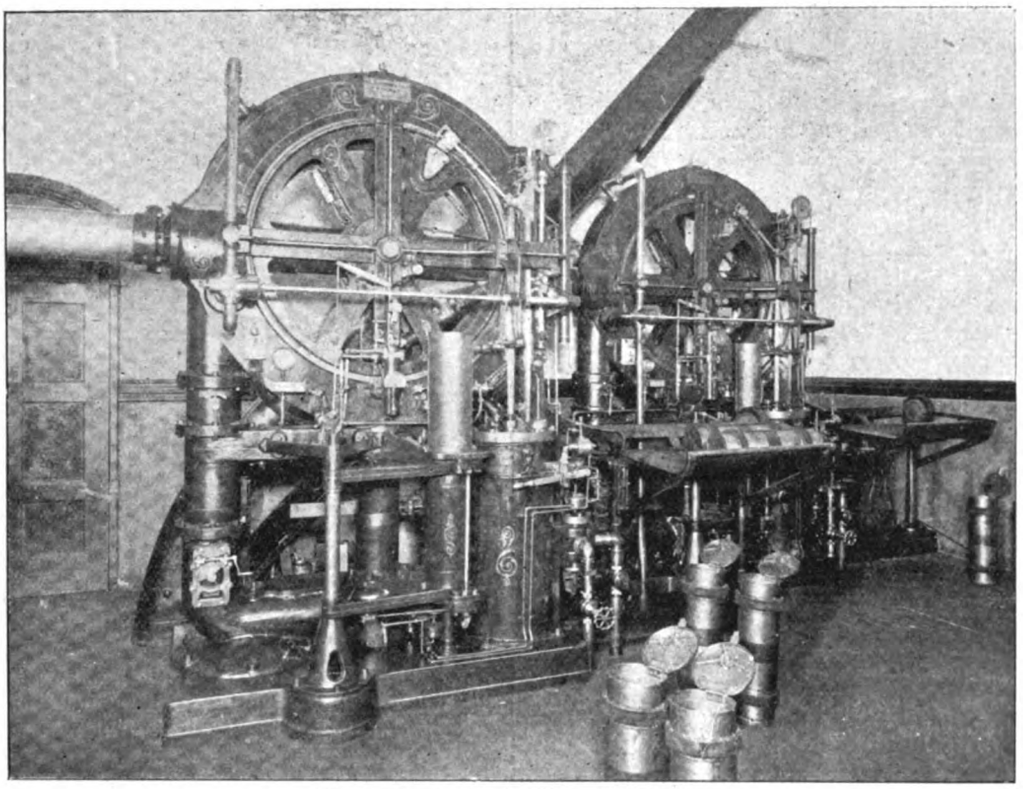
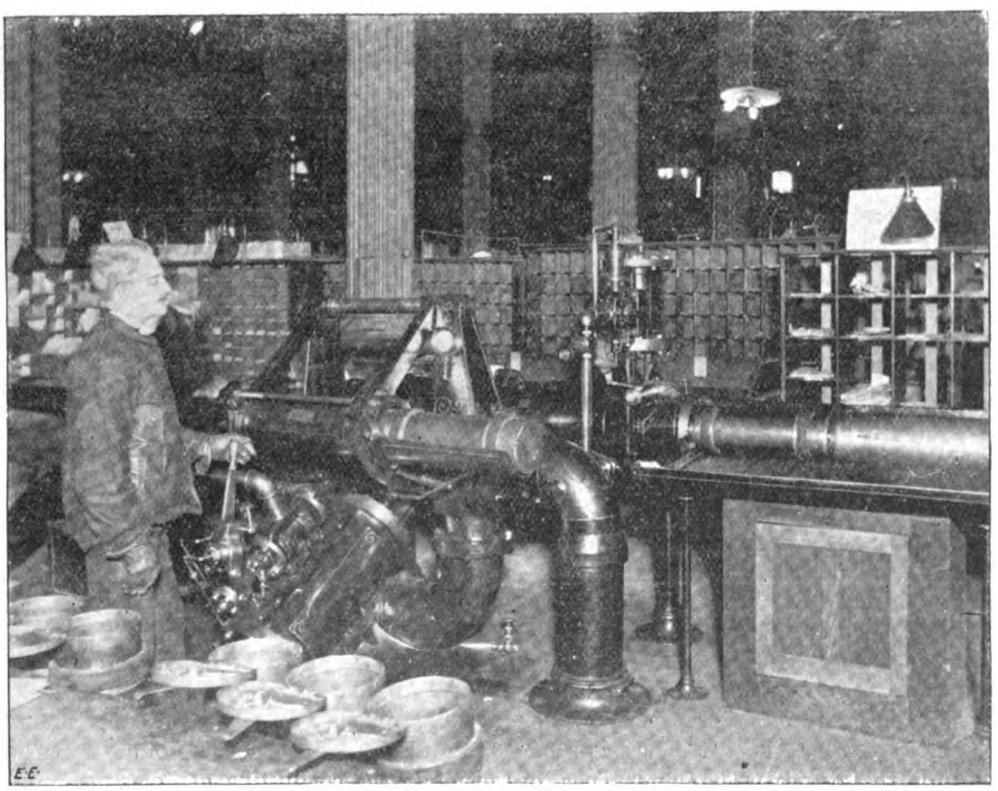
## THE PNEUMATIC-TUBE SYSTEM OF DISPATCH.

At a recent meeting of the Municipal and County Club, Sir John Wolfe Barry, his associate (Mr. C. A. Brereton), Colonel Crompton, C.B., and Mr. K. E. Stuart (engineer to the Batcheller Pneumatic Tube Company) gave a description to a number of metropolitan borough engineers and surveyors of the scheme for dispatch of letters and parcels in London on the pneumatic-tube principle which will be laid before Parliament next session. On each route it is proposed to lay a pair of 12in. tubes at a depth of about 6ft., with electric mains alongside, and between the tubes a telephone line for use in connection with the system. It is calculated that these tubes will permit of nearly 90 per cent. of London's parcel traffic being thus transmitted. Receiving and dispatching offices to the number of 172 will, according to the scheme, be located over the Metropolis at short intervals, and pedestrian messengers will perform the bulk of the delivery. By this means it is considered that the greater part of the vans for delivering mails and parcels (which represent over 20 per cent. of London's traffic) will be obviated, so contributing to the solution of the traffic problem. Large establishments like Harrod's would have an installation on their premises.



Selective Receivers as installed in Philadelphia.



Tube Terminals at Boston (U.S.A.) Post Office.

Another important consideration is the question of saving

Digitized by Google

time, and upon this one or two examples may be given. A letter from Charing Cross to Liverpool street occupies by post three hours; by tube transit it would occupy 20 to 40 minutes, or by an express system of tube transit 10 to 15 minutes. This express service would, it is claimed, be not only more expeditious but cheaper than the existing Post Office system. Other advantages are that deliveries would be more frequent, and letters could be posted up till a later hour; in fact, one of the fundamental ideas of the scheme is smaller consignments and quicker deliveries as compared with the existing system.

The essential features of the Batcheller pneumatic tube system are: (1) a suitable conduit or tube; (2) a receptacle or carrier for passing through it; (3) a device for dispatching the carrier, called a transmitter; and (4) a device for arresting the carrier and delivering it from the line, called a receiver. The carriers are operated by a uniform current of air at low pressure created by electric motors, which would be much more economical than the system used on the old Euston tube. These carriers consist of a light steel cylindrical cartridge, and it has been found in practice abroad that there is no danger of entanglement. The cylindrical steel vessel travels upon a pair of bearing rings placed near each end of the carrier. The rings are of specially-prepared composition, and the carrier travels 10,000 miles upon them before they are worn out, when they can be replaced at moderate expense. The object of the transmitter is to introduce the carrier into the air current without interrupting the flow. The receivers are of four types, each adapted for some special condition. The simplest, which is also the newest, has no moving mechanism whatever. In each of the other three types the carrier is brought to rest by the air cushion formed ahead of it in entering the closed section of tube. When placed where the pressure of the line is atmospheric, the carrier is automatically discharged by the opening of the gate that normally closes this section. Where the pressure of the line is above that of the atmosphere a special form of receiver is provided, which delivers the carrier without escape of air. Colonel Crompton spoke enthusiastically of the ease with which the receiver brings the carrier to rest. Such articles as eggs, pigeons, and kittens have been transmitted with perfect safety, although travelling at from 30 to 40 miles per hour.

One of the most ingenious features of the apparatus is the arrangement by which letters and parcels are delivered at the desired station. Stations other than terminal offices are provided with a piece of mechanism called the intermediate receiver. By means of metallic discs of graduated diameter, carried on the front end of the carrier, this machine selects the carriers intended for delivery at that station, and passes all carriers for stations beyond. The operation is performed by two slender metallic pencils or needles in the head of the machine. These are placed at such a distance apart as corresponds with the diameter of the metallic disc on the end of the carrier. If the disc is large enough to span the distance between these needles, the electric circuit is formed which operates the mechanism that discharges the carrier from the tube. The operator has merely to attach a disc of the size corresponding to the station to which he is dispatching, and the carrier goes there automatically and is discharged from the tube without further attention. We reproduce an illustration of this selective apparatus as installed in Philadelphia, U.S.A., and also a view of the tube terminals at the Boston, U.S.A., Post Office. In America, by the way, 8in. tubes are employed, but the promoters have increased the diameter, as mentioned above, for the present scheme so as to render it more comprehensive.

Regarding the opening of the streets, the promoters and their eminent technical advisers consider that traffic disturbance can be reduced to a minimum by employing the "cut-and-cover" method, and in a large number of cases side streets can be utilised. Colonel Crompton and Mr. Brereton, who have seen the system at work in America, as well as Mr. Stuart, who has had experience of its working, testified to the facility of its operation, and quoted the expressions of unqualified admiration which it evoked from the New York postmaster.

An experimental installation has been laid down at Fulham, where the promoters will welcome visits from anybody interested in the scheme.

## WIRELESS TELEGRAMS TO SHIPS AT SEA.

The first day of the New Year marked the inauguration of a commercial scheme which will be highly appreciated by those who spend part of the time each year in crossing the Atlantic. In official terms this new arrangement for transmitting wireless telegrams from any telegraph office within the United Kingdom is announced as follows: "The Postmaster-General has made provisional arrangements with the Marconi International Marine Communication Company for the acceptance and prepayment at telegraph offices in the United Kingdom of telegrams for transmission from wireless stations on the coast to ships at sea. The arrangement will come into operation on New Year's Day. The charge will be 6½d. a word, with a minimum of 6s. 6d. for each telegram." Of this charge 6d. goes to the Marconi Company, which is a moderate sum for the convenience of receiving definite private information at sea. The arrangement is one of considerable significance both for the Marconi Companies and for the general public. Hitherto, wireless messages have freely passed from ships at sea to the Marconi Companies' shore stations, and thence over the postal telegraph system to their destination. The whole rate for the transmission of the telegrams—viz., the wireless rate from ship to shore and the postal telegraph rate over the inland system—has been collected on the ships by the Marconi operators in charge of the stations there. The Marconi operator at the shore station has, on receipt of a wireless message from a ship, handed it in at the nearest postal telegraph office, paying, of course, the Post Office charges. When, however, messages had to be transmitted from the shore to the ship, the matter was not so simple. In the first place, the general public had no information of the movements of ships carrying the wireless apparatus, or of the locality of the shore stations through which messages might be sent at certain times. Further, any Marconi telegraph station on a ship was not recognised by the postal telegraph officials as an address. Anyone desiring to send a message, for example, from London to a passenger on the "Lucania" could only telegraph the message to one of the Marconi Companies' shore stations, paying only the inland telegraph rate at the telegraph office from which the message was dispatched, and leaving the wireless rate from the shore to the ship to be collected on the ship from the addressee. Apart from the objection to compelling the addressee to pay the wireless rate on receipt of the message, a good deal of knowledge as to the movements of the ships and as to the locality of the Marconi Companies' shore stations, not obtainable at the telegraph offices, was necessary. So crude were the facilities available that the wireless traffic from shore to ship has been practically nil.

All this will now be changed. Anyone desirous of sending a message to a ship at sea by wireless telegraphy will be able to obtain at any telegraph office information as to the ships fitted with the Marconi apparatus, the shore stations with which the ship comes into communication, and the hours during which the ship is within range of such shore stations. The whole rate of the transmission—the land charges to the point where the message passes to the Marconi system, and the rate for transmission over the Marconi system—that is, from the Marconi shore station to the wireless apparatus on the ship—will be collected by the Post Office authorities, the land charges being, of course, retained and the wireless rates handed to the Marconi Companies.

For some years the companies have been endeavouring to secure these facilities, but they have only recently achieved success. The difficulty has been two-fold—partly a disinclination on the part of the Post Office to exchange traffic with companies carrying on such a novel business as the transmission of messages by wireless telegraphy to a moving object (ship at sea), and partly failure in certain quarters to recognise the necessity to the companies of such facilities as these for which they asked.

Digitized by Google

The present agreement is thus welcome, as showing that the Marconi system is now open commercially for the dispatch of messages to steamers at sea.

For use, we presume, of the telegraph offices throughout the United Kingdom, the Marconi Company have issued a list of the proposed sailings of all ships carrying Marconi telegraphs during the present month. In this list there are no less than 29 sailings from European ports and 27 from either New York or Boston. The following extracts from this list will show the general character of the information given. Thus the "Campania" leaves Liverpool on Jan. 14. It can be communicated with from the Rosslare station of the Marconi Company at midnight of Jan. 14, and from Crookhaven station at noon on Jan. 15.

The "Vaderland" leaves Antwerp on Jan. 14. It can be communicated with from the North Foreland station at 3 p.m. on Jan. 14, from the Niton station at midnight the same day, and from the Lizard at 11 a.m. on Jan. 15.

In the same way the times given for the ships leaving America show that telegrams can be dispatched to the same a day or so before they are due to arrive at their European ports. The scheme now inaugurated does not include transmission of messages to ships in mid ocean. Such intercommunication is regularly maintained with many of the best liners, and we are given to understand that a service of private messages will be arranged in the near future. The charge for transmission will, however, be greater than the rates given above. At present the long-distance messages provide the news for the daily papers published on these liners and the weather reports sent to the *Daily Telegraph*.

## THE GLOVER ALMANAC.

The third annual tear-off sheet almanac issued by Messrs. W. T. Glover and Co. is as interesting as either of its two predecessors. This year a vast improvement has been made in the binding of the sheets, which prevents one tearing off a half-year in looking through the almanac for the first time to see what it contains. The feature this year is the inclusion of the photographs of a large number of central-station engineers. One would not suppose from looking at these that the engineer-in-charge of electric lighting works had a happy time, but it must be remembered that the photographer was without doubt the disturbing element when the portrait was made, and thus it would not be fair to put some of the expressions down to the running of the plant in the towns in which the engineers in question are engaged. Another new feature is the insertion of a number of original contributions of an interesting and humorous nature, which tends to lighten the publication. As last year, we think it only fair to the firm to reprint one or two of the daily sheets in order to show the humour which can be extracted even from an engineering profession. Thus, for Jan. 1 we have some remarks on New Year's resolutions (with apologies to Mr. Dooley):

"Well, sir," said Mr. Dooley, "we are in th' nixt year again, an' th' pavin' season has opened down below. Th' surveyor there is layin' out new r-roads f'r th' flagstones made be folks whin they wint home la-ast night. There's nawthin' like a New Year's Eve f'r repinting your wickidniss iv th' past whin ye're singin' God save Oireland, or f'r makin' resolooshuns f'r th' future whin ye're tryin' to pit your key into th' wrong dure. Take th' mannyfacturers now, full iv punch an' mince pies in th' bussum iv their families; an' feelin' so peaceful wid all th' wurruld that they raysolved to divide th' profits iv this year with th' staff. An' every mimber iv th' staff, who are all wishin' to marry this year, tellin' his sweetheart in th' parlor that onless he gits a roise befure th' nixt month he'll leave to onct. Contractors comin' home fr'm St. Paul's raysolve not to send another pennyworth iv ordhers to th' Blankety Blank Company, an' Insultin' Ingineers wake up, whin they hear th' Church Bells an' swear they'll never ask f'r discounts again.

"Perfessors, burnin' th' midnight oil, as Hogan says, an' absorbed in the pa-apers iv last year, pause whin they hear th' whistles an' raysolve to become Insultin' Ingineers. Th' Sicrety iv th' Institooshun was raysolvin' to dhrop th' tripper biz'niss an' make a bee-line f'r foundayshun stones an' portraits iv past-prisidints. I dunnaw where th' Station Ingineers was last night, but if ye asked me I might be right; but they was all raysolvin' f'r to scrap their mains an' ordher Glovers' Cables. Here, Jawn, raise your glass an' may everybody keep to their good resolooshuns."

On Jan. 8 an extract is given from Mr. D. H. Morton's remarks before the Institution of Electrical Engineers. This extract is headed "The Engineers' Creed."

"If one is to be esteemed an advanced engineer to-day, one must believe in the electrical transmission of power and in the internal-combustion engine. I believe in the electrical transmission of power and in the internal-combustion engine, but I am not lost in adoration, nor do I believe that there is but one method of generating and but one method of transmitting and distributing power. Rather, I believe that, with equal skill and zeal exercised in each case, the difference between one system and another is never so great as the retained advocates of each would have us believe. Each system has its physical limitations; those of electrical transmission are the widest, therefore electrical transmission is likely to be the most used and universally employed"

The following extract from Mr. John F. C. Snell's contribution to a discussion before the Municipal Electrical Association appears on May 1. We can quite conceive of the resident engineers of smaller towns reserving this extract for the attention of the chairman of their committee. In those places where salaries are increased in January we are afraid that the leaflet for May 1 will not rest in Glover's almanac until the appointed day for its removal.

"I think it wise that a municipality should engage an independent expert engineer to launch the undertaking and to assist in the selection of a capable chief officer. This officer being appointed, will then seriously consider local conditions, and if he is worth anything at all, will devote his energy to the proper and careful development of the work entrusted to him. But being young and ambitious he will be naturally allured to another town offering a wider field and a bigger salary, and I have known men who have been allowed to leave because their councils have been niggardly, and have declined to increase salaries which were entirely disproportionate to their serious responsibilities. One does not hear of the like changes on the staffs of the larger companies. A change of management in such a case must affect temporarily the progress and development of the system, for it takes time for a new man—however capable—to acquire a thorough knowledge of local conditions, and even a slight change of policy may cost the municipality a great deal of money. Councils, I think, want to form an idea of the depreciation of the engineers, the wear and tear on whom is a really serious factor, for the responsibility of electrical supply undertakings is a very heavy strain. I think more encouragement is required to be given to officials of proved efficiency."

The almanac will have a hearty reception.

## ELECTRIC LIGHTING PROVISIONAL ORDERS (SESSION 1905).

The following is the complete list of applications for provisional orders deposited with the Board of Trade, under the provisions of the Electric Lighting Acts, 1882 to 1890, for consideration in the 1905 session of Parliament:

| Title of Order and Description of Area. | Name of Promoters. |
|---|---|
| Airdrie Burgh Electric Lighting Order (Transfer of Powers and Amendment). | The Scottish House-to-House Electricity Company, Limited. |
| Andover Electric Lighting Order.—The Borough of Andover. | The Corporation. |
| Ballaghaderreen Electric Lighting Order.—The Town and Townland of Ballaghaderreen, and the Townlands of Lung, Friarshill, Knockanaconny and Kilcolman, all in the Rural District of Castlerea. | The Rural District Council. |
| Barnet Electric Lighting Order.—The Urban District of Barnet. | The North Metropolitan Electrical Power Distribution Company, Limited. |

Digitized by Google

| Title of Order and Description of Area. | Name of Promoters. |
|---|---|
| Barton-upon-Irwell Electric Lighting Order.—The Rural District of Barton-upon-Irwell. | The Lancashire Electric Power Company. |
| Bishop's Stortford Electric Lighting Order. — The Urban District of Bishop's Stortford. | The Urban District Council. |
| Brentford Electric Lighting Order.—The Urban District of Brentford. | The Brentford Electric Supply Company, Limited. |
| Brentford Electric Lighting Order.—The Urban District of Brentford. | The Metropolitan Electric Supply Company, Limited. |
| Brockenhurst and Milton Electric Lighting Order.—The Parishes of Brockenhurst and Milton, in the Rural District of Lymington. | Messrs. Christy Bros. and Middleton. |
| Burslem Electric Lighting (Extension) Order. — The Urban District of Tunstall. | The Corporation of Burslem. |
| Bury Rural District Electric Lighting Order.—The Rural District of Bury. | The Rural District Council. |
| Clewer and Old Windsor Electric Lighting Order.—The Parishes of Clewer Without and Old Windsor, in the Rural District of Windsor. | The Windsor Electrical Installation Company, Limited. |
| Coatbridge Electric Lighting Order (Transfer of Powers and Amendment). | The Scottish House-to-House Electricity Company, Limited. |
| Conway Corporation Electric Lighting Order.—The Borough of Conway. | The Corporation. |
| Croydon Rural District Electric Lighting Order.—The Rural District of Croydon. | The County of London Electric Supply Company, Limited. |
| Cults and District Electric Lighting Order.—Portion of the Parish of Peterculter, in the County of Aberdeen. | Messrs. Lowdon Bros. and Co. |
| Denny and Dunipace Electric Lighting Order.—The Burgh of Denny and Dunipace. | The Corporation. |
| Dorchester Electric Lighting Order.—The Borough of Dorchester. | The Dorchester and District Electric Supply Company, Limited. |
| Dover Electric Lighting (Extension) Order.—The Parishes of Hougham, Poulton, River, Alkham, Ewell, Whitfield, West Langdon, East Langdon, St. Margarets-at-Cliffe, West Cliffe, and Guston, in the Rural District of Dover. | The Corporation of Dover. |
| Durham Districts Electric Lighting Order. — The Rural District of Durham and portion of the Rural District of Chester-le-Street. | The County of Durham Electrical Power Distribution Company, Limited. |
| Eastbourne Corporation Electric Lighting (Willingdon Extension) Order.—The Parish of Willingdon in the Rural District of Eastbourne. | The Corporation of Eastbourne. |
| Farnham Electric Lighting Order.—The Urban District of Farnham. | The Farnham and District Electric Supply Company, Limited. |
| Golborne Electric Lighting Order.—The Urban District of Golborne. | The Urban District Council. |
| Gosport Electric Lighting Order.—Portion of the Urban District of Gosport and Alverstoke. | The Gosport and Alverstoke Electric Lighting Company, Limited. |
| Grangemouth Electric Lighting Order. The Burgh of Grangemouth. | The Corporation. |
| Gravesend Electric Lighting (Extension to Northfleet) Order.—The Urban District of Northfleet. | The Corporation of Gravesend. |
| Haydock Electric Lighting Order.—The Urban District of Haydock. | The Urban District Council. |
| Hemsworth and District Electric Lighting Order.—Portion of the Rural District of Hemsworth. | The Hemsworth Electricity Supply Company, Limited. |
| Hessle Electric Lighting Order.—The Urban District of Hessle and the Parish of Anlaby in the Rural District of Soulcoates. | The Urban District Council of Hessle. |
| Hipperholme Electric Lighting Order.—The Urban District of Hipperholme. | The Urban District Council. |
| Houghton-le-Spring and District Electric Lighting Order (Transfer of Powers). | Harry James Almond, Esq., and the Sunderland District Electric Tramways, Limited. |
| Inverness Electric Lighting Order.—The Royal Burgh of Inverness. | The North of Scotland Electric Light and Power Company, Limited. |
| Kingsbury Electric Lighting Order.—The Urban District of Kingsbury. | The Urban District Council. |
| Lichfield Electric Lighting Order.—The City of Lichfield. | Messrs. Foote and Milne, Limited. |
| Litherland Electric Lighting Order.—The Urban District of Litherland. | The Urban District Council. |
| Little Hulton Electric Lighting Order. The Urban District of Little Hulton. | The Urban District Council. |
| Little Lever Electric Lighting Order.—The Urban District of Little Lever. | The Urban District Council. |
| London : Woolwich Electric Lighting Order.—The Metropolitan Borough of Woolwich. | The Borough Council. |
| Ludlow Electric Lighting Order.—The Borough of Ludlow. | William Norton, Esq. |
| Lytham Electric Lighting Order.—The Urban District of Lytham. | Messrs. Foote and Milne, Limited. |
| Macclesfield Electric Lighting Order.—The Borough of Macclesfield. | Messrs. Foote and Milne, Limited. |
| Marlborough Electric Lighting Order. The Borough and Urban District of Marlborough. | The Marlborough Electric Supply Company, Limited. |
| Penmaenmawr Electric Lighting Order. The Urban District of Penmaenmawr. | The Urban District Council. |
| Pollokshaws (Burgh of) Electric Supply Order.—The Burgh of Pollokshaws. | The Corporation. |
| Ravensthorpe Electric Lighting Order. The Urban District of Ravensthorpe. | The Urban District Council. |
| Renfrew Burgh and District Electric Lighting Order.—The Royal Burgh of Renfrew and portions of the Parishes of Renfrew and Govan. | The Corporation of Renfrew. |
| Rushden, Higham Ferrers, Irthlingborough, and Thrapston (Rural) Electric Lighting Order.—The Urban District of Rushden, the Borough of Higham Ferrers, the Urban District of Irthlingborough and portion of the Rural District of Thrapston. | Edwin Percy Harvey, Esq. |
| Rutherglen Electric Supply Order.—The Royal Burgh of Rutherglen. | The Corporation. |
| St. Albans Rural Electric Lighting Order.—The Rural District of St. Albans. | The St. Albans and District Electric Supply Company, Limited. |
| Southall-Norwood Electric Lighting Order.—The Urban District of Southall-Norwood. | The Urban District Council. |
| Southall-Norwood Electric Lighting Order.—The Urban District of Southall-Norwood. | The Metropolitan Electric Supply Company, Limited. |
| Spalding Electric Lighting Order.—The Urban District of Spalding. | The Urban District Council. |
| Stratford-upon-Avon Electric Lighting (Amendment) Order. | The Corporation. |
| Surbiton Electric Lighting Order.—Portions of the Urban District of Surbiton. | The Urban District Council. |
| Tewkesbury Electric Lighting Order.—The Borough of Tewkesbury. | The Corporation. |
| Tottington Electric Lighting Order.—The Urban District of Tottington. | The Lancashire Electric Power Company. |
| Uphall Electric Lighting Order.—The Uphall Special Lighting District in the County of Linlithgow. | The Linlithgow County Council. |
| Ware Electric Lighting Order.—The Urban District of Ware. | The North Metropolitan Electrical Power Distribution Company, Limited. |
| Whitwood Electric Lighting Order.—The Urban District of Whitwood. | The Urban District Council. |
| Whitworth Electric Lighting Order.—The Urban District of Whitworth. | The Urban District Council. |
| Wimborne and District Electric Lighting Order.—The Urban District of Wimborne, the Parishes of Canford Magna and Kinson in the Rural District of Poole, and the Parishes of Colehill, Hampreston, Pamphill, and West Parley, in the Rural District of Wimborne and Cranborne. | The Bournemouth and Poole Electricity Supply Company, Limited. |
| Woking (Chertsey Extension) Electric Supply Company Electric Lighting Order.—Portion of the Parish and Urban District of Chertsey, the Parishes of Byfleet, Pyrford, Chobham, and Bisley in the Rural District of Chertsey. | The Woking Electric Supply Company, Limited. |

## TRADE NOTICES AND NOVELTIES.

### Calendars, Diaries, etc., Received.

ARMORDUCT MANUFACTURING COMPANY, LIMITED.—A very serviceable desk calendar, rather novel in design, of the tear-off-a-leaf variety. Notes can be made on any leaf ahead, and all notes taken during the year are preserved.

W. H. WILLCOX AND CO., LIMITED, 23, Southwark-street, London, S.E., manufacturers of semi-rotary pumps and Penberthy patent injectors and ejectors, patent wire-bound hose, and general engineers' requisites.

THE SIMPLEX STEEL CONDUIT COMPANY, LIMITED, interior electric conduit manufacturers.

WILLESDEN PAPER AND CANVAS WORKS, LIMITED, Willesden Junction, London, N.W.

*Bound Volumes of* "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, January to June, 1904, now ready.*

## MONEY.

"'Tis money makes the mare to go"—an old and well-known adage; though perhaps a direct meaning it has none, still it forms a very nice and convenient text upon which to sermonise. A well-known engineer discussing prospects before Christmas said, as has many another, that money was tight, and far too dear. What! with a bank rate at 3 per cent. for so many months? Oh, the bank rate is no criterion as to what we have to pay in order to obtain money necessary to carry out new authorised schemes. "Here," said the speaker, "are drawings showing proposed works. The schemes are acknowledged to be good, have every prospect of success, are necessary to fully develop other works in successful operation, and need not be expensive." The question of carrying out such work, of course, depends upon funds being forthcoming, and unless these be obtained *through the usual channels*, there seems little prospect of obtaining them. The usual channel is by the aid of professed financiers, and there seems to be a very general impression that the better the proposed scheme the dearer it is to get money. This seems difficult to understand; but the way it is explained makes it clear. The estimated income is so much, that income means 5 or 10 per cent. upon so many thousands of capital; therefore the capital is made to depend upon the estimated income instead of upon the actual cost of construction. Hence the capital as put forth in a prospectus may be double what is actually required and the payments to the financial fraternity are large, bringing about a large sum sooner or later planted upon the public for which there is and never has been a corresponding asset, and for the issue of which there is no reason except inflated estimates. The labourer is worthy of his hire. True, no one disputes that, nor grudges him his due, but what we are suggesting now is that in many of the schemes carried out by the aid of City financiers the question of due and true hire is never considered. All that governs action is plunder; plunder — the more the merrier. Thus it has come to pass; money is unobtainable for new enterprises except at high rates. A direct appeal to the public for money is almost useless. Honesty of proposers is scouted. The purse holder is led to invest only by a promise of high dividends. He discounts to a certain extent the promise, but bites, on the off-chance that it is one of the few cases where performance is better than the promise. Again our engineer, "What chance should I have of getting the money required direct from the public without the intervention of the financier?" Our reply was diplomatic, with might, may, if, and but looming largely; but in sober earnest, what real chance is there to obtain money in such a way? If, then, the inference we draw is correct, and our present methods of floating companies are as indicated, most of our industrial concerns are over-capitalised, and their balance-sheets must mention assets of doubtful value if they could be read aright. One of the arguments of the anti-municipalist is that the local authorities can obtain money at a less cost than can companies. From this point of view that undoubtedly is so, and will be so long as the financier is paramount. On the other hand, no feasible scheme has yet been suggested whereby the cost of obtaining money can be reduced. The financiers say, "On the whole we do not obtain too great an income," but that is simply because the best things have to pay for the failures, and hence, again, a reason for over-capitalisation when the concern is first rate. The average to the financier comes out all right, but the financier looks at the matter quite differently to the engineer or the parties whose interest is more in the future working than in promotion. Is there a solution?

## THE AMSTERDAM-HAARLEM ELECTRIC RAILWAY.

In our issue for Dec. 2 last we referred briefly to the successful completion of the above undertaking. Through the courtesy of Messrs. J. G. White and Co., Limited, the engineers and contractors, we are now able to give a full illustrated description of this interesting line.

### Historical.

About five years ago a system of electric tramways was constructed in Haarlem by a local Dutch company. This system—the first of its kind in Holland—included a circular route round the city, with two branches, one running north to Bloemendal, a thriving residential suburb, and the other about five miles west to Zandvoort, an important seaside resort. Haarlem contains some 65,000 inhabitants, and is popular among the business men of Amsterdam as a place of residence. The distance between the boundaries of the two cities is 10 miles, and it appeared to a number of people that an electric line connecting them should be a paying enterprise. A concession for such a line was granted several years ago; but the proposed route was rather roundabout, and finally the Holland Steam Railway Company secured control and prevented the fruition of the scheme. In 1901, however, Messrs. Anderhagen and Neumeyer, of Amsterdam, took the preliminary steps towards obtaining a new concession for the construction of a line by way of the direct Government high road, which runs parallel with the steam railroad. It was proposed to construct a line on each side of this high road, thus forming a double track, and in due course the necessary concession was granted. Its principal terms were: (1) That the concessioniare was required to sheet pile the sides of the road (which is bordered by a canal on one side and a ditch on the other) in order to secure the necessary width and stability, and to carry out the whole of the works with the least possible interference with the regular use of the road. (2) The period of the concession was for 50 years from Dec. 31, 1902. (3) All construction plans of every nature were required to be submitted for the Government approval. (4) The period allowed for the construction was two years. (5) The speed allowed for the cars was to be regulated by the Secretary of State, and the speed actually permitted was 22 miles per hour. The Secretary of State was also empowered to fix the maximum fares, but it was generally understood that the maximum fares allowed should be equal to those of the steam road.

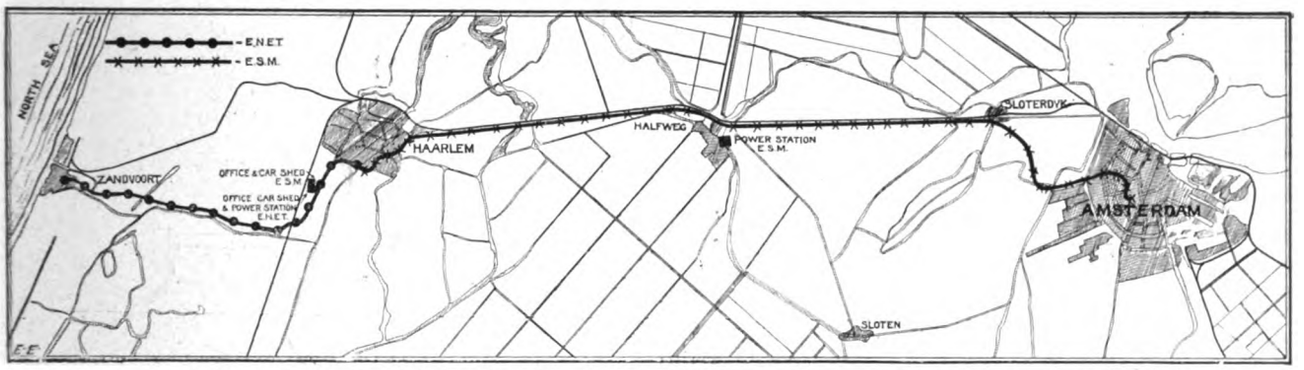

FIG. 1.—Map of Route. Key: E.N.E.T., First Netherlands Electric Tramways; E.S.M., Amsterdam-Haarlem Light Railway.

At the expiration of the concession the Government takes over, without compensation, all the property of the company located on Government lands. There are a large number of minor provisions regarding protection of workingmen, as to hours of labour, accident insurance, pensions, and so forth, and as to the protection of the various water boards, drainage boards, telegraph companies, railways, etc.

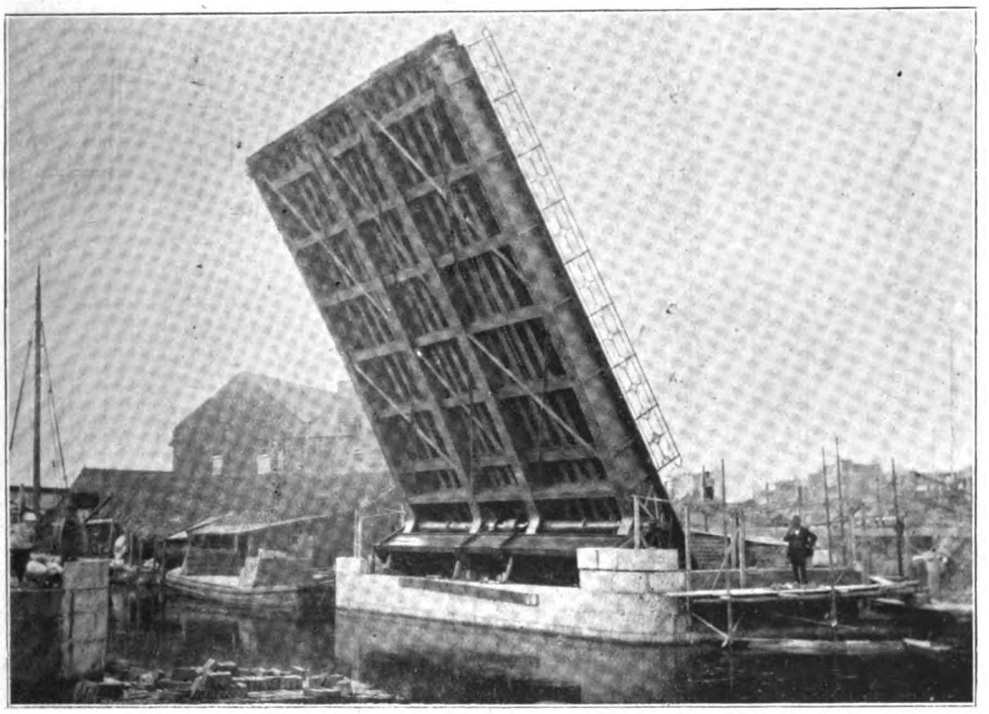

FIG. 2.—Kostverloren Vaart Bridge, Amsterdam-Haarlem Light Railway.

In addition to this concession for the use of the Government high road, it was necessary to obtain an entrance into Amsterdam, and to do this satifactorily the concessionaires obtained options on a private right-of-way for about two miles from the Government road to the Amsterdam city boundary, at a point near the terminus of one of the Corporation tramway lines. In obtaining this private right-of-way, the option was made to include a strip of land for the whole distance, wide enough to permit of a row of building sites on each side of the road being laid out and sold. On this section the tramway is built in a purely private right-

Digitized by Google

of-way in the centre of the road, with a paved carriageway on each side, and outside of this carriageway the usual footpath and building sites are arranged.

Running powers were then secured over the tramways of Amsterdam, then in process of electrification, for a distance of about one mile from the city boundary to the corner of the Spui and the Kalverstraat, the centre of the office and retail business quarters. The gauge of the Amsterdam lines being standard and that called for by the new concession 1m., it was necessary to lay a third rail for the greater part of this distance, where the lines are common, to permit through running of the company's cars over the Corporation route, and this work was carried out by the Corporation at an agreed percentage over cost. A large swingbridge had also to be constructed to permit the through running of the cars. In addition to paying for this bridge and third-rail construction, the concessionaires agreed to pay 40 per cent. of the fares which the town would have charged within the city boundary on the basis of its own rates, and also to refund the actual cost plus 10 per cent. expended by the Corporation for repairs and maintenance of the tracks used by the concessionaires, and, further, to pay for power within the city and taken from the Corporation's trolley wire, at a rate of not less than 0·9d. per car mile. The period of this contract is the same as that of the concession on the Government road. It will be noted that the conditions are most stringent, and that a net profit on the running in the city of Amsterdam could not be looked for; but, on the other hand, the distance within the city was a very short one (1·4 mile in a total run of 12), and to secure the satisfactory terminal facilities these concessions were necessary. Messrs. Anderhagen and Neumeyer then secured an agreement with the Corporation of Haarlem permitting the construction of about 1½ miles of lines within that city, to give the company a satisfactory terminus at its eastern end. The Haarlem concession is also for a period of 50 years, and is without unusual features, except that the concessionaires are required to pay large amounts for the renewal of bridges and similar works along the route.

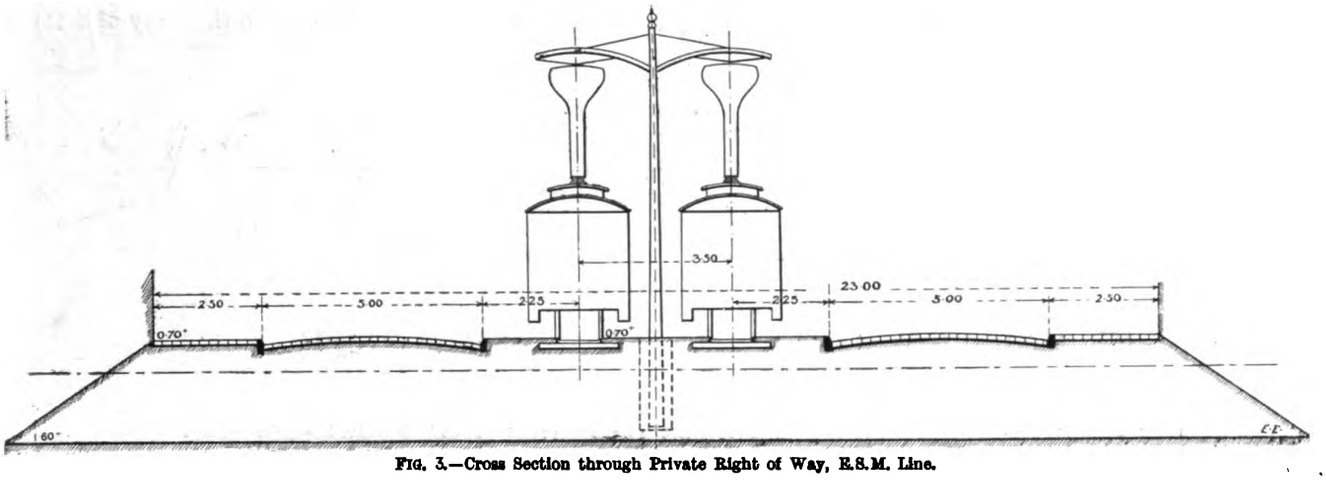

FIG. 3.—Cross Section through Private Right of Way, E.S.M. Line.

When all the concession arrangements above outlined were completed and the local permits obtained, the scheme was submitted to an American syndicate headed by Mr. H. J. Pierce, of Buffalo, who, after full investigation, decided to take the matter up and build and operate the proposed line. The Electric Railway Company of Amsterdam—a Dutch corporation—was formed for the purpose. All the shares of this company were subscribed and fully paid for in cash by the Netherlands Tramways Company of New Jersey, the American syndicate above mentioned. The debentures of an amount equal to the amount of shares—viz, 3,000,000 guilders (about £300,000)—were purchased outright by the well-known Amsterdam banking firm of H. Oyens and Sons. The Netherlands Tramway Company decided that in order to secure more satisfactory terminal facilities in Haarlem and through running arrangements between Amsterdam and Zandvoort, the seaside resort referred to in the foregoing, the local Haarlem tramway company, which had been in operation then for two years, and which is known as the First Netherlands Electric

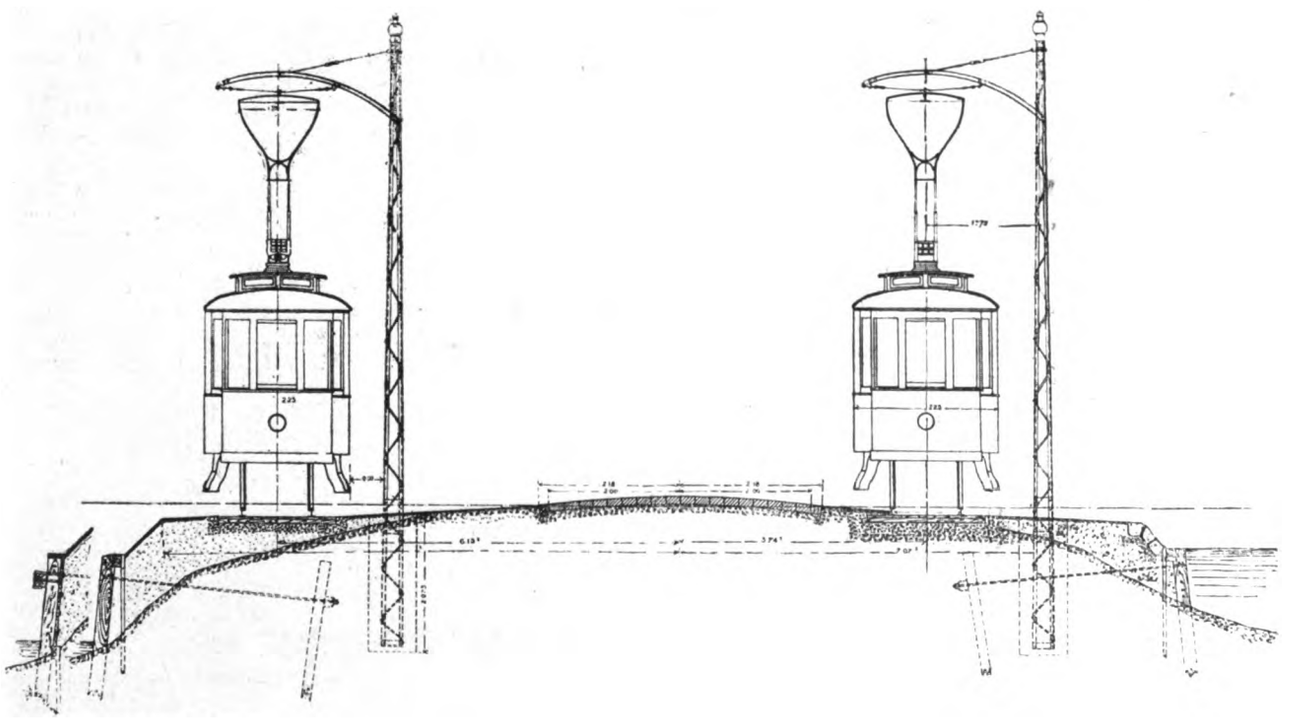

FIG. 4.—Cross Section through Government High Road, showing arrangement of Tracks and Sheet-Piling, E.S.M. Line.

Digitized by Google

Tramways, generally abbreviated to E N.E.T., should be purchased outright. This was carried out, and practically all of the shares of the E.N.E.T. passed into the hands of the Netherlands Tramways Company of New Jersey. The two undertakings are thus consolidated, and for practical working the lines will be operated as a single system.

A contract was then entered into with Messrs. J. G. White and Co., Limited, of London, for the complete design and construction of all the works required, including the permanent way, overhead equipment, power station, car shed, shops, office buildings, bridges, etc., for the

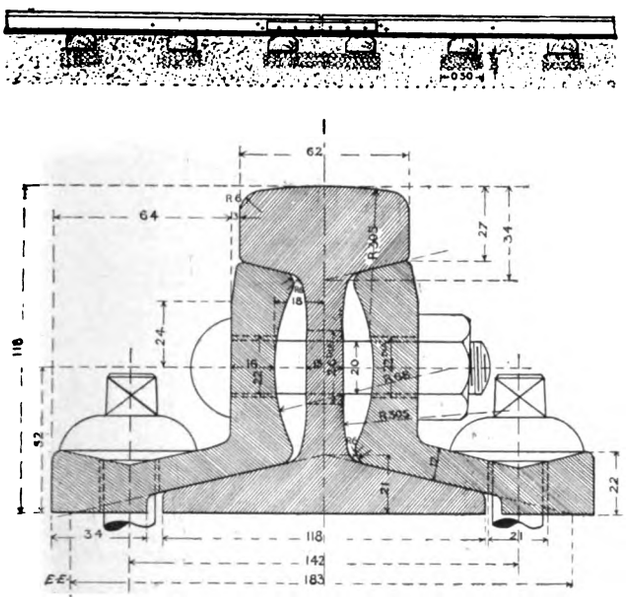

FIG. 5.—Details of Rail and Joint used on Government High Road and Private Right of Way.

Amsterdam-Haarlem inter-urban system, and the reconstruction and additions required by the E N.E T., including the double tracking of the line running to Zandvoort, increase of office and car-shed accommodation, and extension plant in the power station serving this section. The contract was signed on Jan. 1, 1903, and the operation of the completed system commenced in October, 1904. It was intended to inaugurate a service of cars in the spring of 1904, but the works were delayed, due to the failure of the Corporation of Amsterdam to complete bridges, and the delay in getting the approval of the Municipality of Haarlem.

## The Route.

Referring to the accompanying map (Fig. 1), the almost direct route taken by the lines from the centre of Amsterdam to the Zandvoort terminus will be at once appreciated. It will be noted that the designations E S.M. and E.N.E T. distinguish respectively the Amsterdam-Haarlem inter-urban line from that of the First Netherlands Electric Tramways. The bridge (Fig. 2) at the point of junction between the Amsterdam Corporation's and E.S.M. lines is known as Kostverloren Vaart. This bridge was designed and constructed for the Amsterdam Municipality by the Haarlem Machine Company at the cost, as before mentioned, of the Electric Railway Company. It is what is generally known as the bascule type of swing-bridge, and not being easily adaptable for an overhead construction the cars run across it by momentum. There has been found to be no difficulty in this, notwithstanding the fact that there is a considerable ascending grade and a sharp curve on the Amsterdam approach. It should be mentioned that the bridge is operated electrically. The current for working the tramcars to this bridge, and also for working the bridge itself, is furnished by the Municipality, though there is a cable connection made under the canal to enable current to be supplied from the company's mains in case of failure on the west side. For the further information of the reader it may be stated that the bridge in question has a span of 39ft. 6in., and is 39ft. 6in. wide, while some 876 piles and 230 cubic yards of other timber were used in connection with the foundations. It also contains 1,620 cubic yards of brickwork, 130 cubic yards of granite, and 220 tons of steel. Bearing in mind the above quantities, it is almost unnecessary to add that loose sand, that characteristic of Holland, had to be contended with during the construction.

From this point for a distance of about two miles the line runs over what is known as the private right-of-way. The cross-section of the road (Fig. 3) over the greater portion of this part of the route measures 72ft. from building line to building line, a strip 26ft. 6in. wide being left in the middle for tramway tracks with centre-pole construction. The average level of the ground was 5ft. 3in. below the Amsterdam datum, and the height of the finished road was 2ft. 3in. above, so that 7ft. 6in. of material had to be added. The total filling in corresponding to these figures works out at 200,000 cubic yards, but the actual amount of sand brought on to the work was 350,000 cubic yards. There was therefore used on the work 150,000 cubic yards more than shown on the embankment. This is accounted for by the bad soil, the additional amount sinking into the ground. The sand was conveyed in scows to the works from a distance of 12½ miles. It was unloaded from the canal, by means of elevators, into trucks, and hauled by engines on to the road. On this private right-of-way two steel bridges and one of wood had to be built. The first mentioned have a span of 16ft. 4in. and a width of 39ft. 6in. Some 440 piles, with 93 cubic yards of additional timber, 400 cubic yards of brickwork, 26 cubic yards of granite, and 20 tons of steel, enter into their composition. There was also used for the approaches 500 piles and 130 cubic yards of other timber.

At the village of Sloterdyk (see the accompanying map, Fig. 1) the line joins the Government high road, between Amsterdam and Haarlem. On the north side of this road is a canal running the whole length, except through the village of Halfweg, while on the south side there is a ditch. The ground over this distance is what is known in Holland as "polder land." The land itself is below the canal level. It is divided by ditches, generally running in a north-easterly and south-westerly direction. These ditches lead to various points, where windmills are placed to pump the water from the low level up into the canals. The land is of a boggy, peaty nature, and is used wholly for grazing purposes. One of the conditions of the concession, it will be remembered, was that the sides of this road should be sheet piled, and this piling constitutes perhaps the most interesting feature of the whole scheme. It is shown in the cross-section (Fig. 4). On the north or canal side of the road the distance from centre to centre of the piles

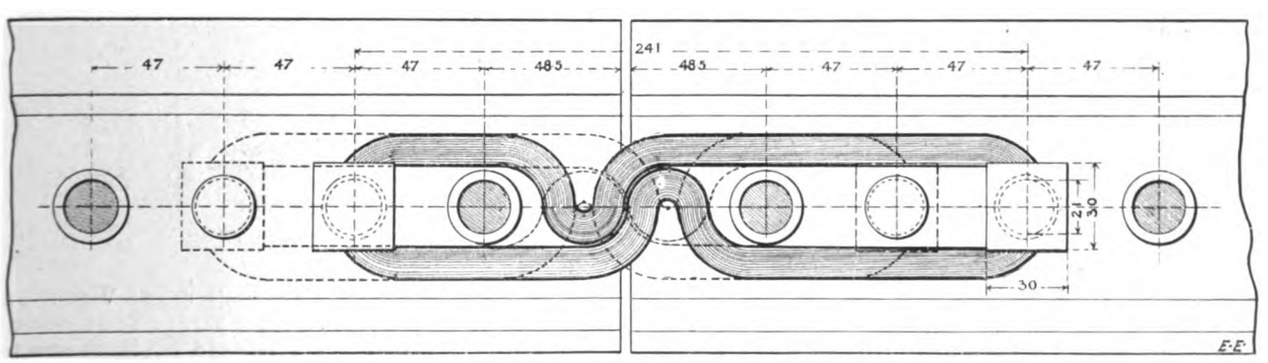

FIG. 6.—Double Concealed Rail Bond.

Digitized by Google

is 1·25m. They are of heavy kolders or hellens, measuring about 22cm. at the top and 18cm. diameter at the point. Their length is 5m. A purlin 13cm. by 20cm. of squared pine is carried along this piling, being bolted to the piles. The bolts are made with square heads countersunk into the wood. Behind this purlin a row of planks, 6cm. thick and 2·50m. long, are driven in, each plank being 28cm. by 30cm. wide. These planks are fish-mouth jointed, and each is fixed on the purlin with three spikes. They are driven in perfectly vertical, and the joints are of good workmanlike fit. At the back of every other pile two anchor piles are driven in. Behind these

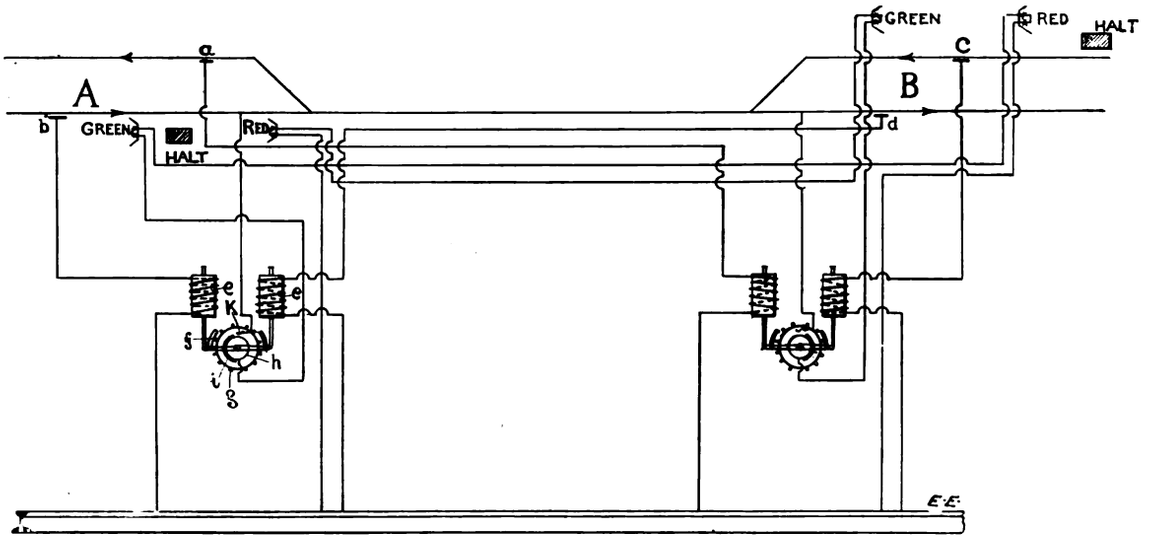

FIG. 7.—Diagram of Connections to the Siemens-Schuckert Automatic Signalling Apparatus installed at Halfweg.

again there is an anchor plate of wood. These plates are tied to the sheet piles with 25mm. round iron rods.

On the south side of the road the piles are of roughly-dressed creosoted pine, 6m. long, 22cm. diameter at the head, and 18cm. diameter at the point, the distance between the piles from centre to centre being 1·10m. The back of this piling is shuttered with boards 5cm. thick of creosoted pine, the joints being covered with strips of timber. This shuttering reaches to a depth of 10cm. below the summer level of the water in the ditch, a purlin 8cm. by 18cm. being fixed to the piles underneath it. Behind the purlin a row of pine planks 6cm. thick are driven to a depth of 3m. For anchoring every alternate pile two anchor piles 3·50m. long are driven in, and to these are attached anchor plates, which in turn are tied with the purlin by means of 25mm. diameter iron rods 4m. long. The space between these retaining walls has been filled in as shown in the cross-section (Fig. 4). Before commencing the sand filling the turf was carefully taken up and stacked, the subsoil and other material being also removed. Pure sand was then deposited in level layers and well rammed down, a coarse gravelly variety being used under the railway sleepers to a depth of 15cm.

At the south side of the road, where the height of the slopes is more than 60cm. above the top of the sheet piling, the slopes are built up with sods in graduated layers. The remaining slopes and the surface of the filling, as far as the sleepers, are covered with either sods or turf 10cm. thick. Where the latter is used grass seed has been planted. The slopes on the canal side above the sheet piling are covered with basalt, which gives them an exceedingly neat and durable appearance. A layer of broken bricks is placed between the sand filling and basalt, the finished pitching having a slope of 1 in 1. The paving of the high road was practically relaid the entire length, to the stipulated datum level of Amsterdam. Some idea of the immense amount of work involved on this section of the route may be gathered from the following quantities of materials used: 20,500 uncreosoted and 23,000 creosoted piles; 3,500 cubic yards uncreosoted and 2,450 cubic yards creosoted timber; 160 tons of iron for tie-rods; 5,000 tons of basalt for projecting slopes; 100,000 cubic yards sand filling; 37,500 square yards of brick paving; 5,700 cubic yards of dredging; 1,850 yards of fencing; and 74 gateways and approaches to farms and houses on the south side. When the work was in full swing on the entire line there were employed 2,360 labourers, two steam locomotives, one electric locomotive, 31 steam pile drivers, three steam spouters, one steam crane, 60 hand pile drivers, one steam bucket rigger, and 165 flat boats and scows.

## Permanent Way.

The permanent way along the Government high road, and also along the private right-of-way, is practically a steam railway construction. The rails are of Vignoles or T section (Fig. 5), weighing 70lb. per yard. The section is the standard of the American Society of Civil Engineers for that weight. The rails rest directly on the sleepers, spaced 2ft. 6in. from centre to centre, except at the joints, where the distance between the centres is 1ft. 7in. The joints are staggered. The sleepers are of creosoted Norway pine, 23cm. by 11·5cm., the upper edges being bevelled. The rails are fastened to the sleepers by screw bolts. Double concealed bonds (Fig. 6) are placed at each joint. The length of route along the canal is 8½ miles. At the village of Halfweg, which, as the name indicates, is situated approximately half-way between Amsterdam and Haarlem, the line crosses two canals. Over these bridges were built

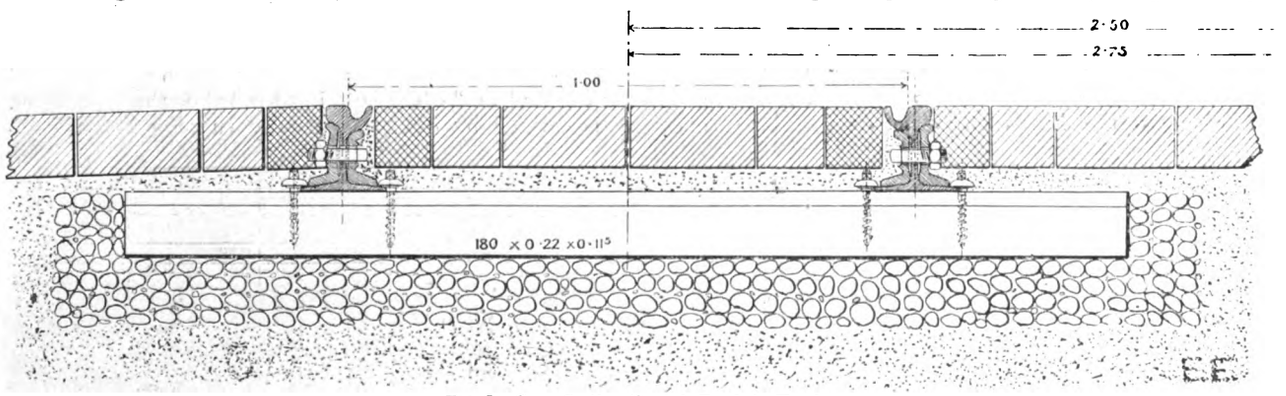

FIG. 8.—Cross Section through Track in Haarlem.

Digitized by Google

specially for the purposes of the tramway. One bridge has four spans, each 49ft. 6in., and the other two spans of the same length, all mounted on piles.

Through the village of Halfweg there are two sections of single line. These short sections are controlled by an automatic electric signalling device of the Siemens-Schuckert

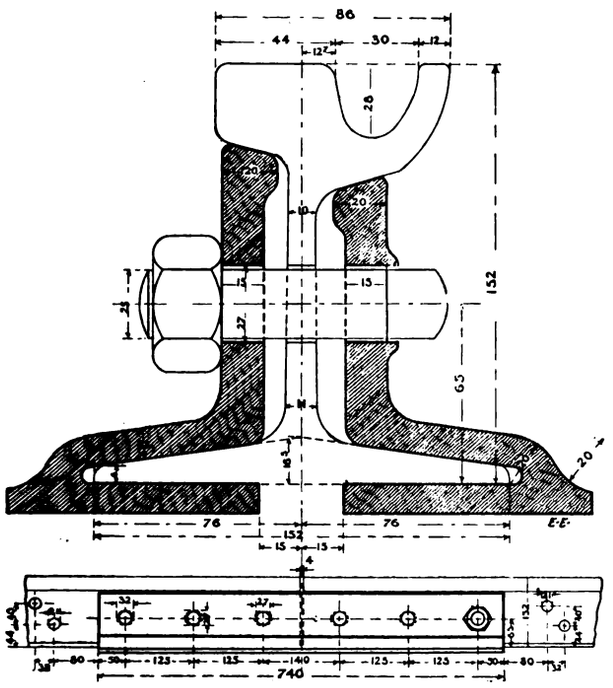

FIG. 9.—Details of Grooved Girder Rail and Continuous Rail Joint used in Haarlem.

Company. This apparatus is designed to prevent two cars entering upon a section at the same time in opposite directions, when both ends of the section cannot be seen by the driver at one time. The connections are shown in the accompanying diagram (Fig. 7). At each switch point this toothed wheel is a contact wheel, *h*, with one segment, *i*. The segment, *i*, forms, with the spring, *k*, an arrangement for breaking contact in the circuit of the light signals in such a manner that the contact is usually broken; therefore, no light burns when the section is free—that is to say, when no car is passing between A and B. As soon, however, as a car enters the section in the one or other direction, a turning movement acts on the toothed wheel, the lamps are lit, and when the green lamp is alight the signal is free, and when the red lamp burns the signal is at danger. When, now, the car leaves the single-track section and touches the contact apparatus in connection with the trolley wire, the toothed wheel is turned in the opposite direction, by means of which the spring, *k*, slips off from the segment and the lamps are extinguished. It is easy to see that the apparatus works in exactly the same manner for several cars following one after the other, and that the number of cars is only limited by the number of teeth on the toothed wheel. By the entrance of each car into the section, the wheel is turned forward one tooth, and by the same car leaving the section it is turned back by one tooth, so that the lamps are extinguished only after all the cars have passed out of the section. If we now follow the course of a car from A to B (Fig. 7), we notice that the car on nearing the point A touches the contact piece *b*, and through a stirrup operates the relay as above described. The spring, *k*, touches the segment, and the green lamp lights up, and is seen from the car, showing that the track is open. At the point B the red danger signal appears; the section, therefore, is closed for cars coming from the direction of B. After the car has passed the stopping place, it passes through the single-track section, and, making contact with *d*, works the relay in the opposite direction, and the lamps are extinguished. The same process is gone through when cars pass from B to A, with this difference, that the relay at B lights or extinguishes the lamps. Should the two cars make contact at *b* and *c* simultaneously, red and green lights appear on both sides. But the arrangement is such that in this case the car coming from B will see only the green light, which means "free track." The car coming

FIG. 10.—Special Track Work at Kleine Houtweg, Haarlem.

where cars enter and leave, similar contact pieces, *a*, *b*, *c*, *d*, are installed, which by the passing of a car are connected by means of a stirrup with the trolley wire, current being thereby caused to flow for a brief period through the windings of an electromagnet, *e*, whereby the armature of the magnet is drawn up, and a ratchet, *f*, is engaged with a toothed wheel, *g*, and at the same time this toothed wheel turns through one section of its circumference. Firmly connected to from A, however, will see from its stopping place only the red light danger signal, and will, therefore, be obliged to wait until the first car has passed the section. The apparatus and signal lights are attached to poles near the switch points. The contact pieces through which the relays are operated are spaced a short distance from the signal lights on the span wire, while the signal wires of silicon bronze, 2mm. in diameter, are carried by porcelain

Digitized by Google

insulators attached to cross-pieces of angle iron, which in turn are fixed to the poles between the cross-arms carrying the feeder cables and telephone wires.

At what is called the "Amsterdam Gate" the line enters the city of Haarlem. The terminus in Haarlem coincides with the terminus of the Zandvoort line, belonging to the E.N.E.T. system. Grooved girder rails, weighing 84lb. to the yard, are used in Haarlem. They rest directly on the sleepers, spaced 2ft. 6in. centre to centre, except at the joint, where the spacing is 2ft. The dimension of the sleepers is the same as for the Vignoles track. Fig. 8 illustrates the track construction mostly employed in Haarlem, while Fig. 9 gives the details of a continuous rail-joint also used, special work in course of execution being the subject of Fig. 10. In this town it was necessary to reconstruct a swingbridge, entirely rebuild three other bridges, and to construct a new bridge for the tramline only at the Amsterdam Gate. The new car-shed (Fig. 11) was constructed alongside the existing power station of the E.N.E.T. The car-shed track rails are supported directly on cast-iron columns. These columns have flanged bases, resting on the piled foundations. The length of the columns is 7ft. 3in., and the depth of the pit in the clear 4ft. 6in. The distance from centre to centre of the columns is 6ft. 6in. The rails bridge this distance without any additional support. This construction gives the minimum of obstruction in the pits, and is simplicity itself. Vignoles type rails, with a rolled guard-piece bolted on, as shown in Fig. 12, are used for the curves into the car-shed.

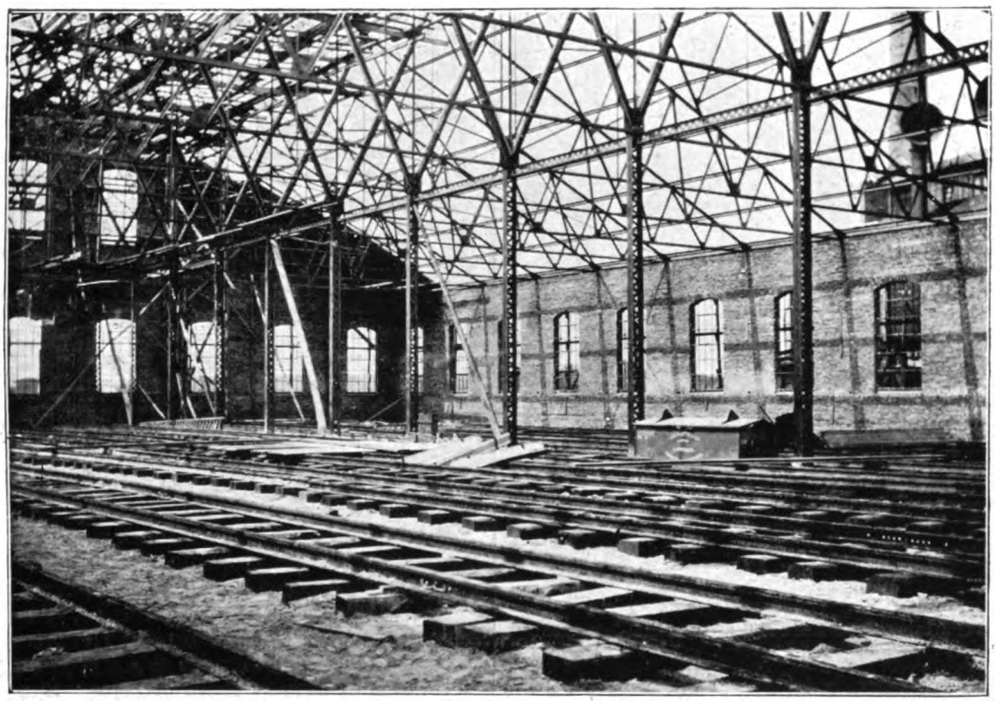

FIG. 11.—Car Shed in course of erection, Haarlem.

## Power Station.

The power station is situated at Halfweg, which is practically the best position for distributing power to the line, being almost central. It adjoins the Ringvaart Canal, which will afford cheap carriage for coal and other supplies, besides abundance of water for feed to boilers and jet condensation. Owing to the nature of the subsoil at the site, an elaborate arrangement of piling was necessary, the entire site being piled with 46ft. long by 9¾in. diameter piles, placed 4ft. 1in. apart, each pile being estimated to carry four tons. On top of these piles runners 7⅞in. by 9¾in. are carried, and support a floor 3in. thick over the space occupied by the building. The piling is carried below the water-level to a distance of 3ft. 7⅜in., and from this point the foundations rise to the floor level, a height of 7ft. 2⅜in.

The buildings (Fig. 13) are of brick, substantially and neatly finished with stone trimmings. The area of the site is about 9,150 square feet, with sufficient additional ground for future extensions. A wharf (shown in the section, Fig. 14), 26ft. 3in. wide, is erected alongside the canal, and immediately adjoining this is the boiler-house, measuring 88ft. 7in. by 52ft. 6in. The engine-room is 59ft. by 34ft. 7½in., by 21ft. 4in. high from floor-level to top of wall. Situated at one end of the boiler-house is a coal storage room, 50ft. 8in. by 35ft. 4in, with storage capacity for 400 tons. An outhouse for offices communicates with the engine-room. The walls of the buildings are 14in. thick above and 21in. thick below the ground line, being strengthened by pilasters 14ft. 9in. apart and 21in. thick, which are carried to the top of the walls for supporting the roof principals. These latter are of tee section rafters, with angle struts and flat bar ties securely riveted to suitable plates. The purlins are of channel iron with wooden runners, and supported by angle-iron brackets fastened to the principals. The whole of the slopes are covered with red tiles secured to a wood lining, which is fastened to the purlins.

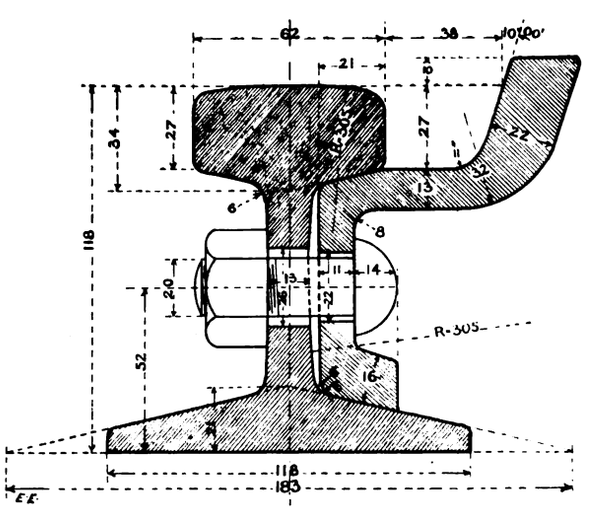

FIG. 12.—Rolled Guard for Tee Rail.

A monitor, 9ft. 10in. wide, is formed along the full length of boiler-house, each side being filled in with nine rows of louvre boards. Wooden gutters with zinc linings are provided along the tops of walls, with suitable drain pipes, which convey the rain-water to the ground-level, or to a tank placed on the roof, the supply from which is utilised for washing purposes. Good light is obtained throughout the entire building by large glass windows with iron frames, and ample door space is provided for bringing machinery into the building. The travelling crane works over an area of the engine-room at a height of 15ft. The gantry

Digitized by Google

construction is of tee rail resting on wooden beams and supported on brick arches.

## Equipment of Power Station.

*Boilers.*—The boiler-house (see Fig. 15) contains six Lancashire steel boilers, by Stork, of Hengelo, Holland, the heating surface of each boiler being 926 square feet, grate area 35 square feet, steam pressure 160lb. per square inch. The boiler shell is 7ft. 6in. diameter by 27ft. 10in. long and contains two furnaces, each 2ft. diameter, and having five Galloway tubes. The boilers are stoked by hand. There are also six superheaters. These are placed in the flues directly behind the boilers, and arranged to work at a temperature of 500deg. F. Each superheater has a heating surface of 330 square feet, and consists of 10 rows of coils, the ends of which terminate in two cast-steel headers, 8ft. 11½in. apart, the coils being bound by steel straps bolted together. The steam enters the one header, passes through the tubes, and discharges at the other. Fixed to the discharge steel header is a 1½in. safety valve, a 1in. blow-off cock, and two small holes for testing purposes. The foundations for the boilers are composed of brick arches filled in with sand, and rise from the wooden floor. The boilers are further encased in heavy brickwork walls, and supported on cast-iron stools. By the arrangement of dampers adopted the gases can be made to pass either through the superheater, after passing through the internal flues of the boiler, or the superheater can be cut out, in which case the gases pass along the sides of the boiler to an underneath flue which adjoins the main flue. A round brick chimney, 131ft. high and of 5ft. 5in. internal diameter, is situated free from the building at the end of the boiler-house. This chimney is lined with firebrick set in fireclay, extending from the bottom to a height of 65ft., the foundations consisting of a large bed of concrete 23ft. square by 6ft. deep, and supported by wooden piles 9¾in. diameter by 46ft. long, placed 2ft. 2in. apart.

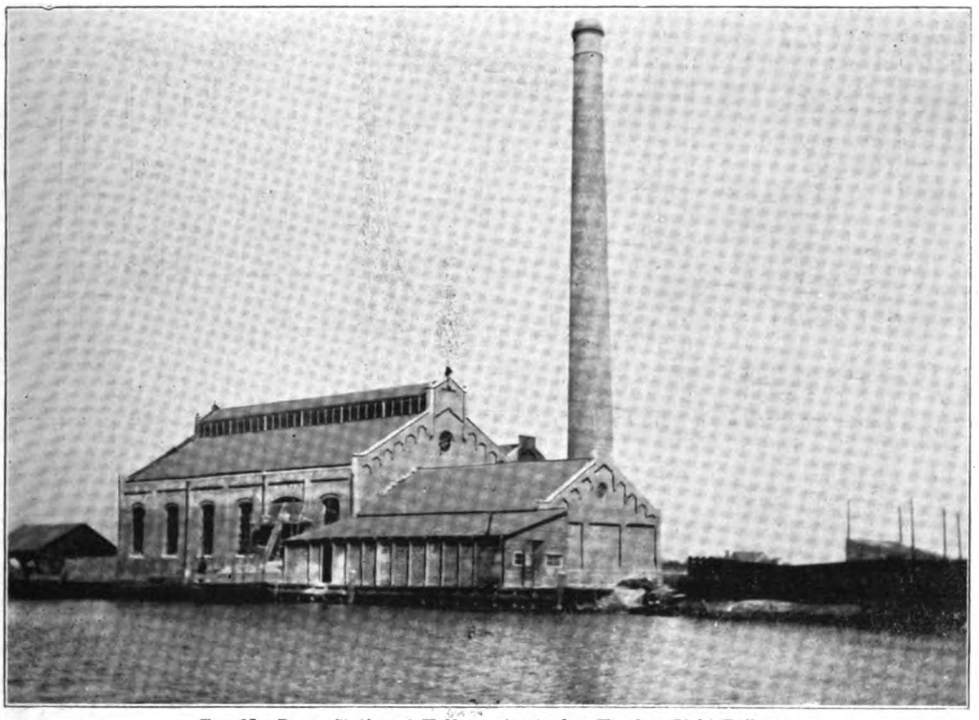

FIG 13.—Power Station at Halfweg, Amsterdam-Haarlem Light Railway.

*Feed to Boilers.*—The feed water for the boilers, as already mentioned, is taken from the adjoining canal. The supply contains a certain amount of suspended matter, necessitating recourse to filtration. Under the stoking floor a duplicate arrangement of brick tanks has, therefore, been provided. Each system consists of a filter tank with reservoir, the filtering medium being composed of sand and clinkers, supported on a wooden perforated floor, thus allowing the water to percolate through the medium to the reservoir. A branch pipe connecting both reservoirs leads to a hot-well. Inside of the hot-well, and fixed to the side of the tank, is a ball-float valve, with connecting pipe to the water inlet supply to the condensers, the latter being used as an automatic emergency water supply in the event of the filtering tanks failing to supply the hot-well. The

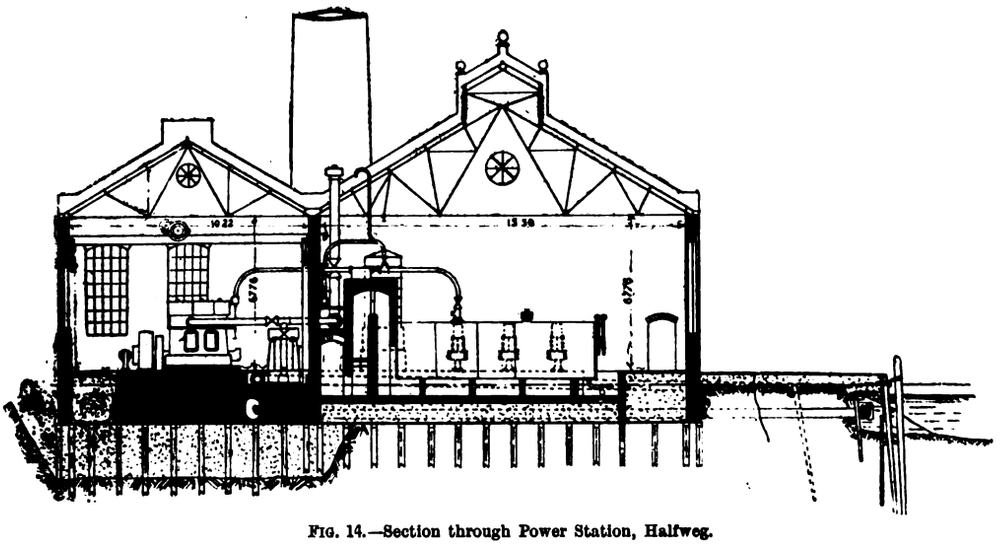

FIG. 14.—Section through Power Station, Halfweg.

Digitized by Google

area occupied by the filter tanks is about 710 square feet. Three sets of direct-driven horizontal duplex feed pumps, 6in. by 3½in. by 6in., made by the Buffalo Pump Company, N.Y., are installed, each capable of delivering 2,400 gallons per hour against 300lb. per square inch, the working steam pressure being 160lb. per square inch. A vertical exhaust feed-water tube heater 9ft. 7in. high by 24⅝in. diameter, by the Wheeler Condenser and Engineering Company, is placed directly behind these feed pumps, the feed water entering at the bottom and leaving at the top, the exhaust steam *vice versâ*. The shell is made of cast iron, while the tubes are made of the best quality seamless drawn brass, fastened to the tube plates at the top end by ferrules and asbestos packing, the bottom end being secured by screwed joints. By removing the upper cover of the heater and the bottom hand-hole plates the tubes can be readily cleaned.

*Main Steam-Piping.*—From the angle stop valves on the boilers 6in. pipes join the cast-steel header of the superheaters, and then branch into the main header, from which the engines take their supply of steam. The piping, which is extra heavy throughout, is arranged by closing valves in the main header to permit the operation of this plant as three independent units. Owing to the high temperature of steam, ample allowance has been made for expansion and contraction, and the piping is designed in such a way that any condensation of steam in the pipes connecting the main header collects in the latter, and is drawn off by three drains of large size, one in each section, so as to prevent any accumulation of water in the pipes. The three drains being coupled to two steam-traps, which can be worked independently, discharge into a drip main, which runs along the division wall between the engine and boiler rooms to the hot-well. A stand-pipe from the drip main

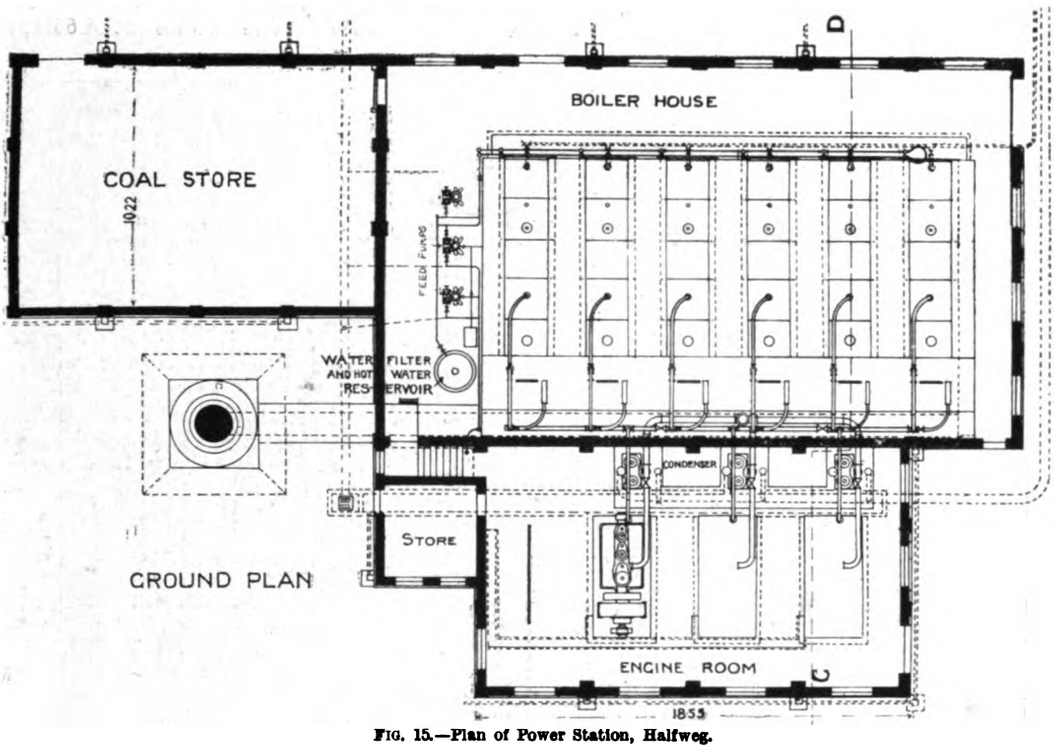

FIG. 15.—Plan of Power Station, Halfweg.

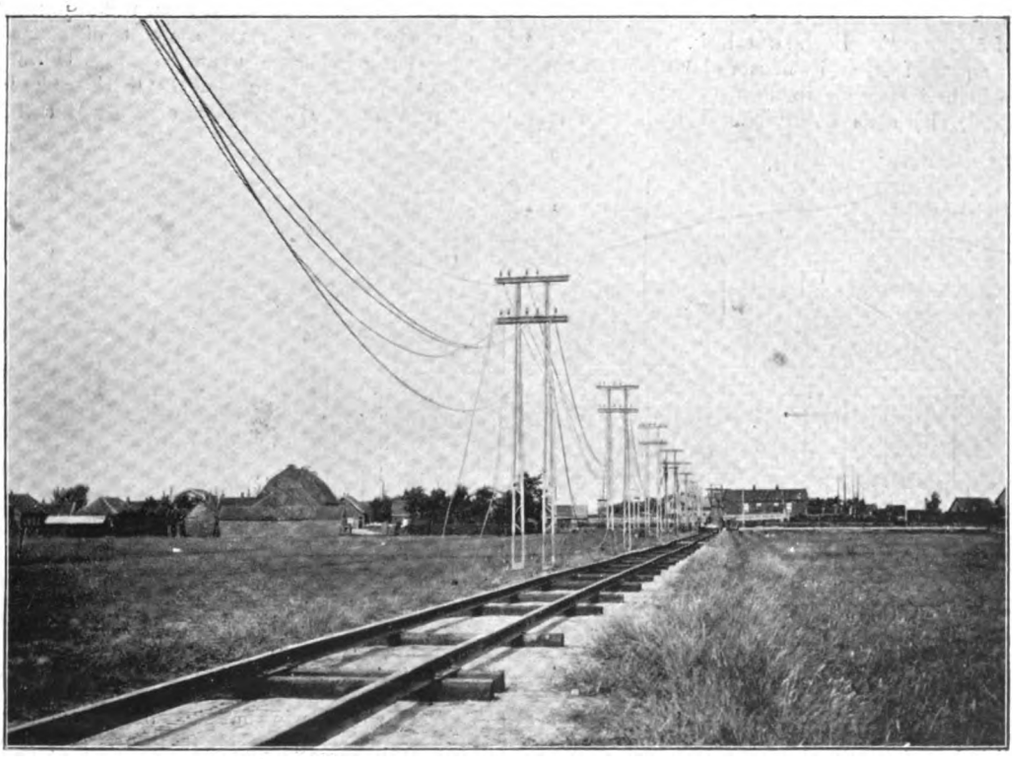

FIG. 16.—Feeders and Returns at Power Station Site, Halfweg.

Digitized by Google

is placed in a prominent position in the boiler-house with its end open, so that any excessive discharge of steam will draw attention to a defective trap. Following are the dimensions of the main steam piping: main header, 8in. diameter; diameter of pipe from stop valve to superheater, 6in.; diameter of pipe from superheater to main header, 4½in.; diameter of pipe from main header to engine, 4½in. From each of the angle stop valves on the boilers a drain is connected to a drip main, which discharges into the hot-well. This drain will only be used in the case of any of the boilers being shut down, so as to prevent water from accumulating in the valve. From the stop valves on the engines are drains leading to traps, which connect with the common drip main and run off to waste.

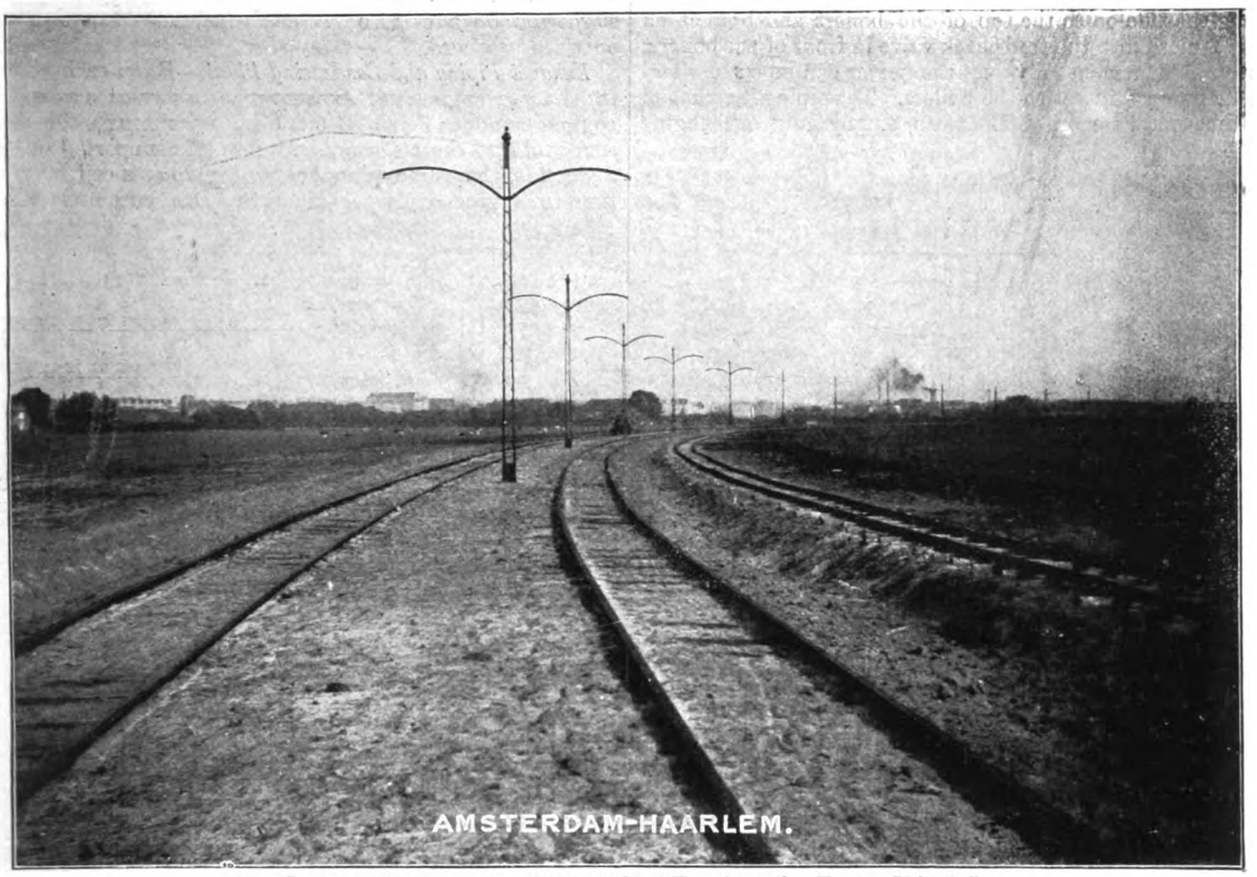

FIG. 17.—Centre Pole Construction, Private Right of Way, Amsterdam-Haarlem Light Railway.

FIG. 18.—Side Pole Construction, Government High Road, Amsterdam-Haarlem Light Railway.

*Feed Piping.*—The feed-water piping to the boilers is arranged in duplicate. The discharge from the pumps passes through the heater into one of two mains which run along the side on to the top of the boilers and branch off to a Y-piece into the feed check valve in front of the boilers. By an arrangement of valves the heater can be cut out and water pumped direct to the boilers. The piping is arranged so that one or more boilers can supply any one engine

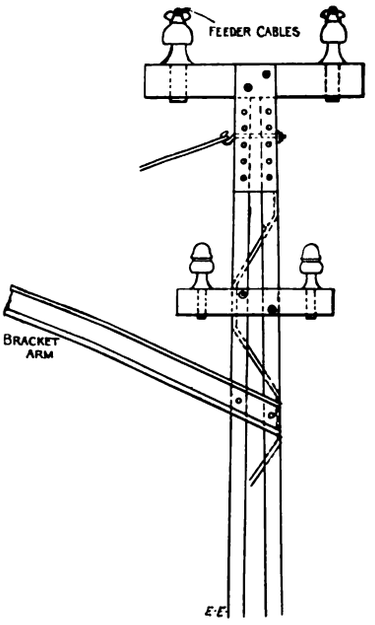

FIG. 19.—Details of Side Pole Construction, showing method of carrying Feeders and Telephone Wires.

independently of the others, and allow the consumption of steam in the engine to be determined at any time. Each of the feed pumps installed is capable of supplying the full amount of feed water required by all the boilers.

*Engines and Generators.*—The main plant consists of three Belliss patent self-lubricating, three-crank, triple expansion engines, each of 430 b.h.p. at economical cut-off, and having a steam consumption of 13½lb. per brake horse-power hour with superheated and 17lb. with saturated steam, with 26in. vacuum. The speed is 375 revolutions per minute, and its regulation is within 3 per cent. even with sudden variations from full to no load. The engines are of the enclosed type, supported on a heavy cast-iron frame, and secured by nine foundation bolts. The cylinders are respectively 12in., 17in., and 26in. diameter with 13in. stroke. To these engines are direct-coupled three continuous-current compound-wound six-pole generators supplied by the Société Anonyme Westinghouse, Le Havre. The output of each machine is 300 kw. at 525 to 575 volts when running at a speed of 375 revolutions per minute. Each generator is supported on a cast-iron frame, which also supports the outward bearing.

*Exhaust Piping and Condensing Plant.*—From each of the three main engines an exhaust pipe is carried across the engine-room at a height of 6ft. 6in, and through the division wall into the boiler-house, where it is supported on the main flue, the three pipes connecting up at a central position to a pipe of larger diameter. An automatic relief

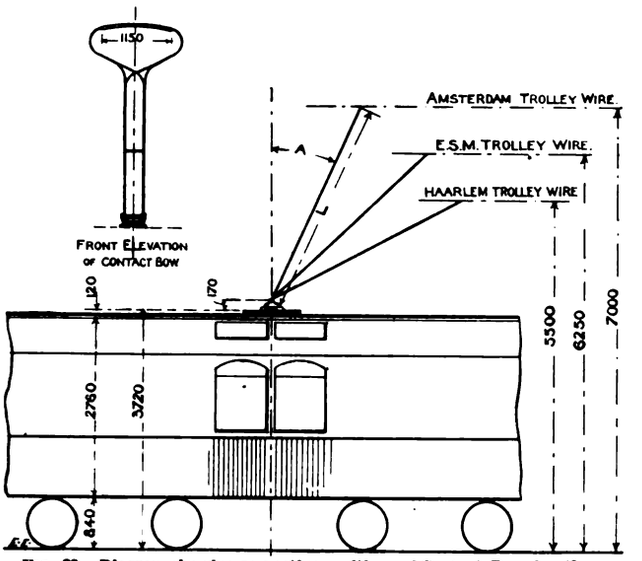

FIG. 20.—Diagram showing respective positions of Contact Bow for the different sections of route.

valve is provided in the vertical pipe leading to the atmosphere, an exhaust header being also attached. A branch pipe is taken from each engine exhaust into an independent jet condenser, by valves situated conveniently in the piping. The arrangement will permit of any one engine working in conjunction with any condenser. The condensation in the pipes drains back into the condensers. The condensing plant itself was made by the Nederlandsche Fabrick, Amsterdam, and consists of three jet condensers, each capable of condensing 9,000lb. of steam per hour. The pumps are of the vertical type, with cylinders placed side by side, and supported by a cast-iron frame. Directly below are the Edwards air pumps. The condenser and injection water inlets are situated behind the pumps, the pumps discharging into a large air vessel placed in front of the pumps. The position of these condensers behind the main engines is shown in Figs. 14 and 15.

FIG. 21.—Motorcar, Amsterdam-Haarlem Light Railway.

Digitized by Google

The inlet water is taken from the canal through a pipe into a channel reservoir built into the foundations of the engine-room, from which channel the suction pipes of the condensers take their supply. A valve placed at the pipe entrance enables the water to be cut off if necessary. The discharge from the condensers takes place into a main which has ample capacity for two additional units, and flows thence into the canal.

It may be added here that the auxiliary units (feed pumps and jet condensers) are worked with saturated steam taken from branches off the main steam-pipe between the stop valves and superheaters. The branches are joined up to a loop system, alternate boilers connecting up one side of the loop. From this, again, a main is taken through a separator into the engine-room, where it branches off to the three condensers. Other branches are taken from the loop to supply the feed pumps.

The exhaust from each of the three condenser engines joins into a main pipe which passes through the division wall into the boiler-house, where it meets a main exhaust pipe from the three feed pumps to the heater, the latter being by-passed through butterfly valves, which can be operated to divert the steam either through the heater into the atmosphere or into the atmosphere direct. Valves are placed in the piping, so that any unit can be isolated when required.

between Amsterdam and Haarlem, the remaining section from the last-mentioned town to Zandvoort being supplied from the E.N.E.T. station, extension plant for which was included in Messrs. J. G. White and Co.'s contract.

## Overhead Equipment of the Line.

A good general idea of the overhead construction along the two principal sections of the line—that is to say, the private right-of-way and Government high road—will be obtained from the accompanying illustrations (Figs. 17 and 18). The poles, it will be noticed, are different to anything met with in this country, being of the latticed girder type, and exceedingly light in appearance. They are of three different weights, respectively 550, 700, and 1,300 lbs. The lightest and medium weight poles are constructed of two channel sections braced together, the heaviest being composed of angle pieces. Heel plates are attached, and the poles are set in concrete to a depth of 6½ft., notwithstanding which it has been found necessary to also provide guy ropes in some cases. The bracket arms each consist of two channel sections braced together, this construction being employed throughout, except in Haarlem, and the poles carry both the feeders and telephone wires. The feeders consist of two bare copper conductors, each of 194 square millimetres section, and are carried at the top of the poles on cross-arms, as shown in Fig. 19,

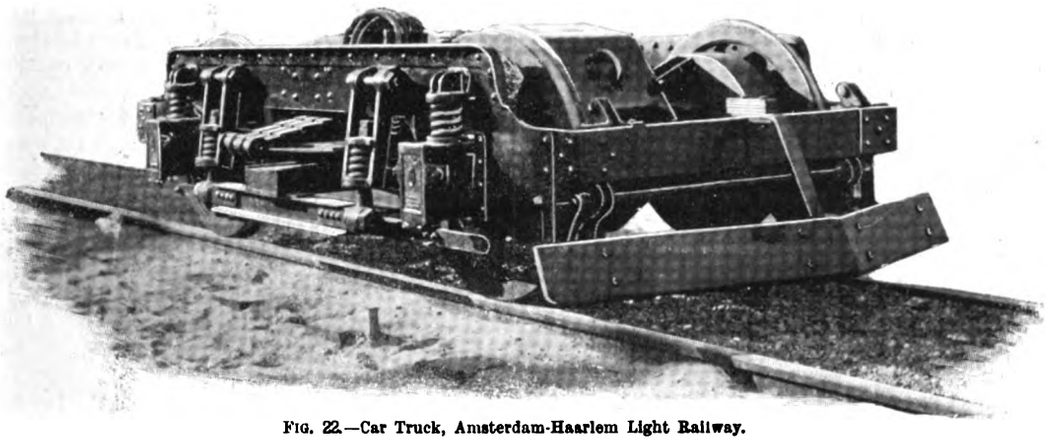

FIG. 22.—Car Truck, Amsterdam-Haarlem Light Railway.

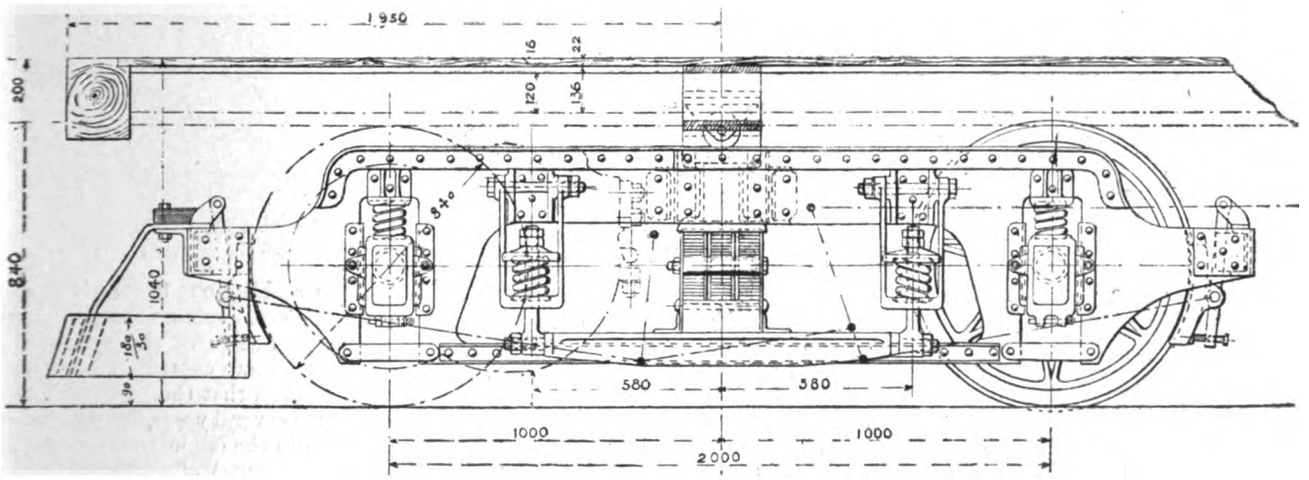

FIG. 23.—Elevation of Car Truck.

*Switchboard.*—The switchboard was supplied by the Société Anonyme Westinghouse, Le Havre. It consists of five marble panels (three generator and two feeder), fitted to a steel frame, and is erected on the floor at one end of the engine-room. The usual complement of instruments, switches, etc., is provided. The cables from the generators are led into a trench which runs along the ends of the machines and terminates behind the switchboard. This trench is covered by chequered plates. The method of carrying the feeders and return cables from the power station to the line is shown in Fig. 16. The voltage on the line differs from that at the switchboard by the amount of loss due to transmission—that is to say, it varies from 575 to 500 volts. It must be remembered that the power station described in the foregoing has to serve only that portion of the line lower arms being provided for the telephone wires. The trolley wire is 68 square millimetres in section, and is zig-zagged, in order to equalise the wear on the bow collectors with which the motorcars are equipped. On that part of the route from Haarlem to Zandvoort bow contact is made with two wires simultaneously. The wire is secured and held up by means of mechanical clips, which, with the bow, ensure noiseless running. The height of the trolley wire from the ground varies for the different sections of the route, as shown on the diagram Fig. 20. This variation in height caused at first considerable trouble with the bow collectors, but at present the bow base is so arranged as to keep an equal tension on the bow at the respective heights. The wear on the bow has been noticed to be very rapid at high speeds when the wire is coated with ice. Lightness pro-

Digitized by Google

vided without loss of strength may be said to characterise the overhead construction throughout.

## Rolling-Stock.

There are 34 motorcars of the type shown in Fig. 21. These were built by La Metallurgique at Nivelles, Belgium. Each car is divided into two compartments, for seating 22 and 12 passengers respectively, being also vestibuled. The smaller compartment is for smoking. Besides the usual hand brakes, the equipment includes a Christensen air-brake, supplied by Messrs. R. W. Blackwell and Co., Limited, London. The air-pumps are worked by an electric motor automatically regulated. The trucks (Figs. 22, 23, and 24) are noteworthy in that the swing hangers are pivoted on the outside of the truck frame. This permits a maximum distance between the supports of the spring plank and a maximum distance centre to centre of the swing hangers. The result of this construction has been most satisfactory, the riding of the cars being remarkably easy even at the higher speeds of 35 to 40 miles per hour. Two motors of 50 h.p. each are used on each car. These were furnished by the Union Elektricitäts-Gesellschaft, now incorporated with the Allgemeine Elektricitäts-Gesellschaft.

## Conclusion.

We need not repeat here the observations as to the prospects, etc., of the above undertaking contained in our issue for Dec. 2 last. Suffice it to say, our personal inspection of the line impressed us with the thorough substantiality of the work throughout and the careful regard for local conditions evidenced by every detail of the scheme. The result reflects great credit upon Messrs. J. G. White and Co., Limited, whose indefatigable representative on the spot during the execution of the contract was Mr. Wood. We trust it will lead to the firm being entrusted with other large schemes on the continent of Europe.

In conclusion, we have to express our indebtedness to Messrs. J. G. White and Co. for the materials from which this article has been prepared.

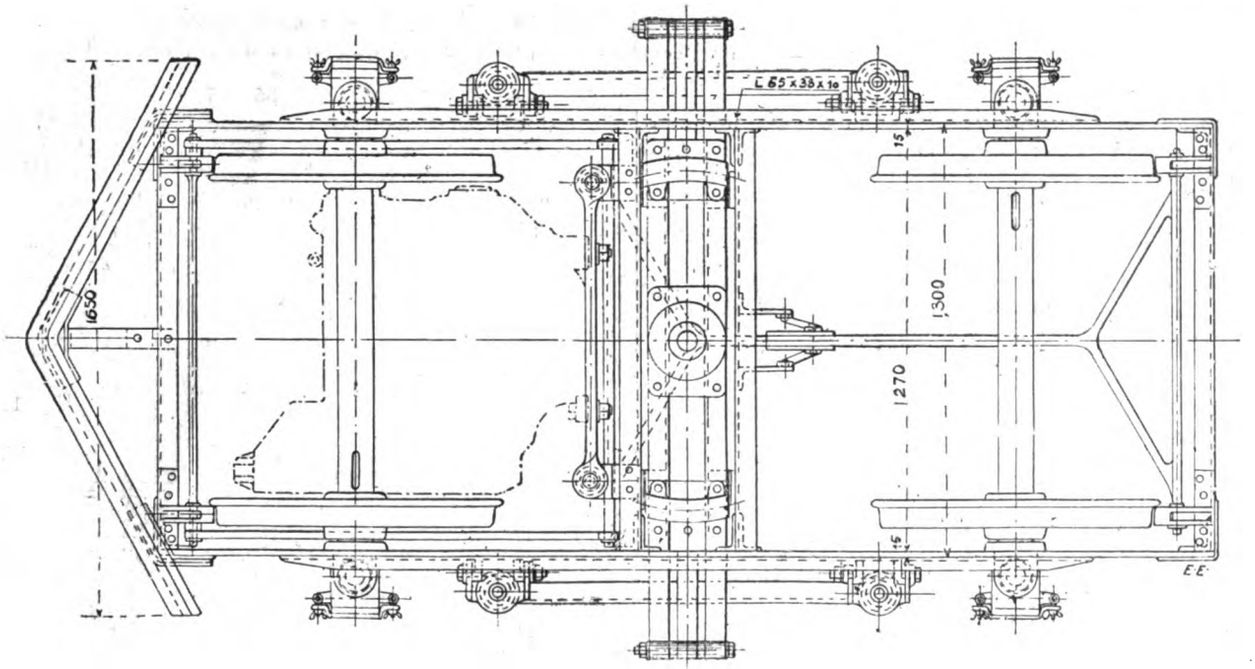

FIG. 24.—Plan of Car Truck.

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

In previous articles contributed to this journal the author has dealt with the design of high-tension, extra high-tension, and low-tension switchgears from various points of view. The present series has for its subject the chief types of oil switches in use, their design and assembly in conjunction with other apparatus to form a power-house or sub-station switchgear. The superiority of the oil switch, and more recently the oil circuit breaker, over the air switch and fuse is now established beyond all dispute where high voltages and large capacities need controlling, so that the respective merits of these types will not be considered. It will be sufficient to draw attention to the effect of opening an air-break switch as shown in Fig. 1, where a very considerable arc is evident across the terminals of a small switch to emphasise the necessity for an oil break under all circumstances. There can be no denying that air-break switches are now in use where present practice would suggest or even compel the employment of oil circuit breakers. But this is no argument for their efficiency. It may be said, rather, that where installed such switches are the bane of the operators, while the management will continually live in fear of breakdown.

The development of the distance-controlled switch has been a comparatively slow one, in that its employment has depended on the size of the plant controlled. In fact, only in really large power-houses has it merited adoption, and, strangely enough, it is in America that it has been most extensively used. Until comparatively recently the large Continental power plants have maintained a supply with air-break switches, while many to this day are entirely dependent on them. In collecting data for this article enquiries were made of electrical engineers of repute on the Continent and in America, and but one firm only among the former supplied particulars of remote-control gears. Whether this is in any way indicative of the attitude of Continental engineers towards remote control it is difficult to say. Of course, it is well known that the basement type of gear has been used abroad for several years, the gear being lever-operated from a platform in the engine-room. As far as the author is aware, few Continental electrical engineers manufacture electrically-operated switches, and such as have them in contemplation are at present reticent in giving details of their design. To America, then, must the credit be given for the exploitation on a large scale of the electric distance-control switch, and English engineers who come later into the field with their power schemes are compelled to adopt their designs even if the apparatus is manufactured in this country. Whatever we may do in the way of making such switches of English design, we are still indebted to America for enterprise and forethought in developing so important an adjunct to large power stations.

In introducing this subject, it will be easier for the reader to follow if the types now employed of distance-control gears are classified under two heads: (1) the manual control and (2) the electrical control. In treating with both these the switches themselves will be first described, and the lay-outs of such subsequently treated at the end of

Digitized by Google

each section. This procedure will enable ready reference to be made to the types of gears coming under each section.

The arrangements and apparatus described in this article are intended to illustrate what is now being chiefly done with extra high-tension switchgears handling pressures now considered as best kept at a distance from the operator. If these are compared with the high-tension gears previously dealt with by the author in this journal, an interesting record of progress will be noticeable, together with that of changes occasioned by the use of much higher pressures and greater powers. Where at one time anything would do for a high-tension gear, and the operator's life or the fate of the station were apparently unimportant, now the operator, or at least the attendant, is completely isolated from the board, and the greatest possible precautions against fire are taken by sub-dividing the gear and isolating the sections thus formed from each other. Seeing that serious arcing

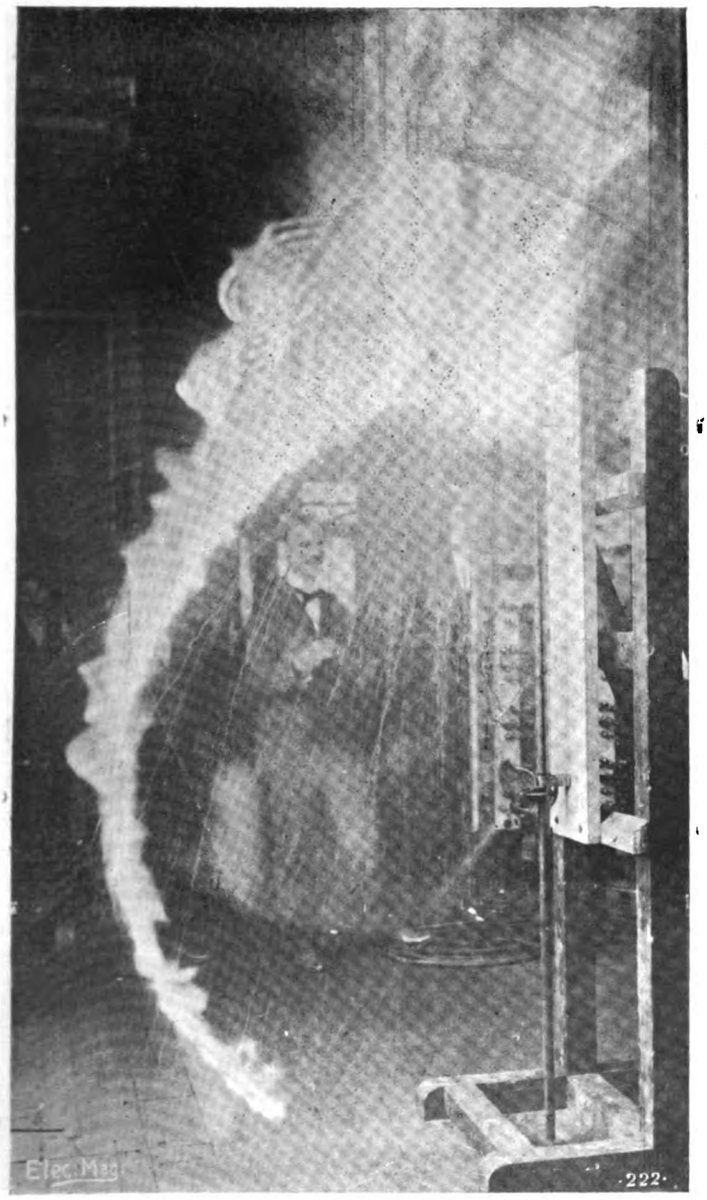

FIG. 1.—Arc produced at Opening.—Air-Break Switch.

if allowed to occur and spread will quickly transform a valuable controlling gear into a heap of ashes, and, perhaps, involve the whole plant, precautions which are really such must be taken to confine that arcing, which will take place on rare occasions, to the faulty apparatus. Unless this is done the gear cannot be safe or considered so. When some individual switch is called upon to deal with the entire output of a station, the necessity for complete isolation becomes even more evident, as failure means that the whole plant will pour its energy into the failing switch.

Perhaps equally important is isolation of phases or parts working at different potentials. In some lay-outs, especially where connections are made to the 'bus bars on the same wall face, assuming the cables enter the bar chamber from below, the first cable presents no difficulty, but the other two must pass through the bottom and middle chambers respectively of the other phases before reaching their particular bar. This method compels the use of insulating tubes for the leads of opposite phase crossing the other bars. Seeing that the most feasible place for the connection is behind the bar, and that the tube may become covered with dust, the arrangement is not conducive to maintaining that standard of safety so closely observed in other parts of the gear. Isolation, if undertaken at all seriously, should be thorough, each particular phase being distinct from generator cable to 'bus bar, from 'bus bar to feeder cable. In no case should it be identified with the other phases or parts from which it differs greatly in potential.

With an air-break lay-out the switches are invariably placed at the top of the board above all other apparatus. Since oil circuit breakers have been used it has often been considered safe to incorporate them in the body of the gear, placing other apparatus above them. This arrangement seems reasonable enough, based as it is on the excellent reputation of the oil circuit breaker. To take every precaution against accident, however, the oil switches should always be placed at the top of the gear, *with nothing between them and the roof* of the switch-house. If partitioned off from their neighbours, any trouble would be confined to the switch itself, and only under abnormal conditions spread to the adjoining gear or plant. Similarly, the cable connections should be *unexposed* in the switch-room, and, where possible, should be below the switch itself. In case of fire destroying the latter, another switch might be quickly got into place, and the cables would have remained intact. The 'bus bars also should be below the switches, and without difficulty can be assembled with the cables (feeder and generator), the instrument transformers, and the section switches. By this method, and with two or three tiers or galleries for the gear, probably the best arrangement to conform to the chief dictates of experience will be found. The relative advantages of manual and electrical control cannot well be discussed here. As the switchgear is the most vital accessory to electricity supply between power plant and consumer, the simpler it can be made, and the less reliant it is on external sources, so much the more immune from breakdown will be the plant be. With lever control, complete confidence is placed in the switchman, on whose muscular efforts its operation will depend; with electrical control, the switchman is still there, but, in addition, some source of electrical energy is needed, and two have to be depended upon instead of one. The ease and flexibility of electric control, however, gives it a powerful advantage over a mass of levers and cranks, and where batteries can be used there should be no trouble from failure of supply. The system requires more thought and skill in its operation and maintenance, but that should not be reckoned a real detriment to its installation. With continued experience of electrical control, we may yet see an automatic switchgear developed, seeing that so much otherwise complicated apparatus can be readily controlled by electrical means. With the questions of 'bus-bar arrangements, selector switches, and sub-division of plant, it will not be possible to deal in this article. Should opportunity arise, these matters will be considered on a future occasion.

## MANUAL CONTROL.

Associated with the development of distance-control switchgears is the small oil "box" switch for hand operation. Various types of these have been constructed, and

Digitized by Google

though largely employed singly in isolated positions, their adaptability for distance control with links and levers justifies some reference to them here. Such switches are remarkably compact for the power they control, while they are free from that *bête noir* of many oil switches—leakage from the containing tanks. They possess another interesting feature which makes possible standardisation of type for many different pressures, thus adding materially to the ease of manufacture. For low pressures the contacts can be enclosed in a single oil bath, hung from the contact support. As the pressures to be dealt with are increased, the contacts can be enclosed in *separate* oil-tanks, while for

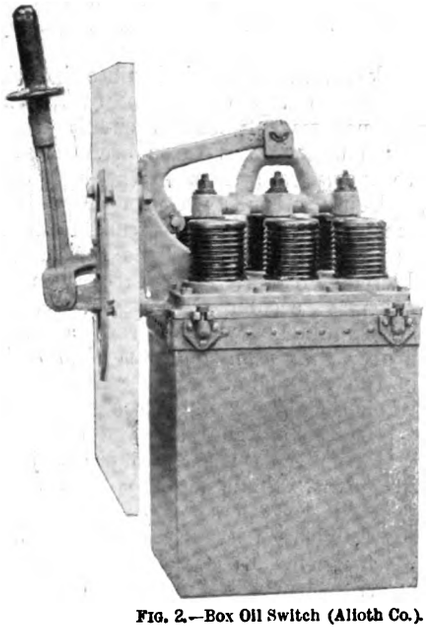

FIG. 2.—Box Oil Switch (Alioth Co.).

higher potentials without increase of power, the contacts can be put in series, giving several breaks under oil in the one circuit. In this case, of course, three switches would be needed, and operation might be cumbersome, though for tandem operation little more room would be required.

As mentioned above, many Continental concerns used the air-break switch for years after the oil switch was its acknowledged superior, but now this fancy for air interruptions and flaming arcs is giving place to a preference for the oil circuit breaker. Fig. 2 illustrates a type made by the Alioth Company, Munchenstein, Bale, a glance at which will at once reveal marked similarity to American practice. In Fig. 3, however, which shows a back view of the

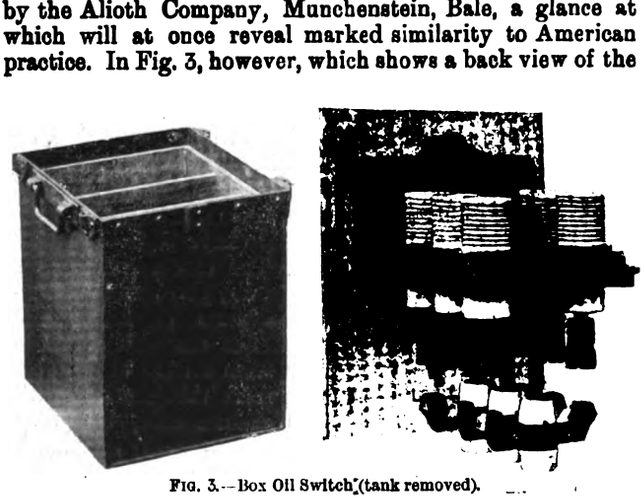

FIG. 3.—Box Oil Switch (tank removed).

switch, the method of mounting the moving contacts will be noticed as dissimilar. A substantial grooved insulator at the end of the vertical rod is used to clip on the bridge contact piece, while the fixed contacts themselves are formed of four distinct strips, which can be readily replaced. A system of parallel links and levers engaging with the casting coupling the switch rods together, and terminating in the main handle, serves to operate the switch. A knuckle joint serves to hold the switch in the "on" position, and when opening, the joint is moved over the dead centre, when the switch mechanism falls sharply by its own weight. The switch is also fitted with a tripping solenoid for operation on overload or reverse currents. The tripping can be derived from a direct-current source or the alternating-current supply through the medium of current transformers. Fig. 4 illustrates the connections for the latter on a three-phase circuit, the secondaries being connected in series through the tripping coil. An armature attracted by the relay normally

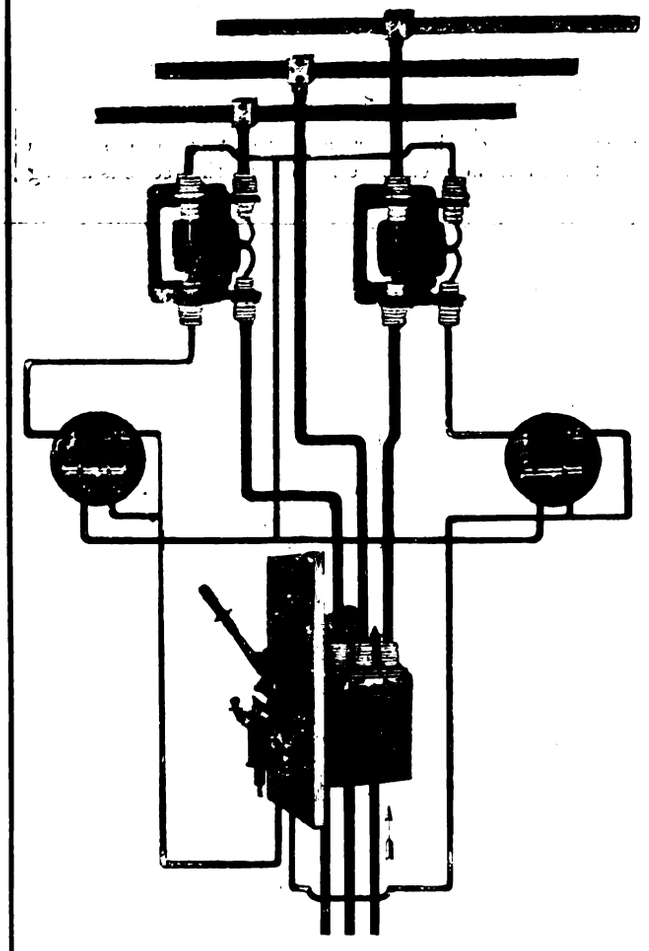

FIG. 4.—Diagram of Tripping Relays and Transformers for Three-Phase Operation.

short-circuits a parallel circuit to the solenoid, but on either relay operating, the solenoid is cut in and operates the switch. The connections and relays are for a maximum-current relay. The author has not been furnished with details of the reverse-current device. Obviously a switch of this character can be operated at any convenient distance, and in the lay-outs to be afterwards described it will be seen that such a switch can be very successfully employed in this particular.

*To be continued.)*

## THE PROPOSED TELEPHONE DEAL.

BY ALFRED R. BENNETT.

The Post Office in the past has admittedly made many mistakes about telephones. It is now about to face a larger and more important operation than ever before, one of which the consequences will be enduring and permanent, whether for good or evil. It is desirable, therefore, to enquire into some of the possible consequences of the contemplated action, and to discuss the various steps or stages which may lead up to it.

As a guide, it would not perhaps be out of place to review what happened when the Post Office acquired the trunk lines some dozen years ago, and discover how we stand now as the result of that proceeding. There can be no doubt that the amount paid for the trunk lines was largely in excess of their actual value. The company was unwilling to sell (as a matter of fact, the sale was an unparalleled and irretrievable blunder on its part), and it

Digitized by Google

very properly drove a good bargain so far as payment for the actual plant was concerned. The blunder lay in the mistaken policy—from the point of view of the company's own interests—of relinquishing the splendid hold on the country which the possession of a trunk system gave it. The Post Office had no power to force a sale otherwise than by giving notice to acquire the whole concern in accordance with the terms of the license. The advantages to the company other than the handsome price it received were illusory, and the directors dropped the real meat while grabbing at a shadow. As the company did not benefit, it might be contended that the Post Office, as the other party to the transaction, must have done so, but that view will not hold good when one reflects that the Post Office acted as representing the taxpayers of the kingdom, and that it could only score a triumph by making a bargain satisfactory to the whole community. This it did not do. Much of the plant it bought was already worn out; much was of antiquated construction and already obsolete in 1892; much, again, was little better than temporary work, insufficient conductors supported on inefficient insulators fixed to inadequate poles; and much was on ground for which no proper wayleaves existed. But the price paid was equal to the cost of the best work quite new. No sooner did the Post Office come into possession than the task of pulling down and re-erecting began, and has continued since until probably there is little or none of the purchased plant in actual operation to-day. The trunk lines have consequently been paid for twice over, and it is not surprising, therefore, that the Post Office find it necessary to charge trunk rates about twice as high as they ought to be, and twice or thrice what are found adequate by Continental telephone administrations. Moreover, it is reported that it makes a heavy loss on the trunk system all the same, but as no proper accounts are published, it is impossible for an outsider to tell whether this is true or not. A by-question that may pertinently be put here is, why no separate and understandable accounts are rendered? But, in addition to the high trunk rates, the Post Office let itself and the public in for what are known as terminal fees, which for short distances amount to as much as the trunk rates themselves, and are a burden always. The effect of these are to put telephone exchanges owned by itself (the Post Office) at a permanent disadvantage as compared with exchanges owned by the National Telephone Company, and their existence has no doubt been one of several reasons why Post Office exchanges have never prospered, but have always been outclassed, sometimes actually run out of existence, by the company's competing systems.

The corporation telephone exchanges suffer under the same disability as a consequence of the ineptitude of the Post Office bargainers of 1892, and if they hold their own, as they do, the fact is in no way due to the Post Office, but rather in spite of it. Again, the Post Office has not done its duty by the trunk lines. One of the reasons assigned for purchase was that the company or companies would connect only the larger towns, which would yield a good return on the capital cost, and neglect all others, although, as a matter of strict fact, a good many small towns had already been joined together several years prior to 1892. As early as 1887-1890 the present writer had connected most of the towns in Scotland, as well as in Cumberland, and had erected the first trunk line across the Border. Most of the towns then dealt with were small, such as Whitehaven, Workington, Maryport, Carlisle, Dumfries, Selkirk, Hawick, Galashiels, Stirling, Dunfermline, Kirkcaldy, etc.; and it may be cited as a curious example of the respective merits of company and government administration that not one of the many trunk lines erected by the author failed to pay interest on its cost within two or three months of its opening. Some yielded a very handsome profit. But what has the Post Office done about small towns? In very many instances it has *refused* to connect them at all in default of a guarantee from the local authority, the subscribers, or even the National Telephone Company itself, of a certain minimum revenue. In fact, it has been less enterprising than the company was before the transfer. As regards the larger towns, it has been quite as remiss. Complaints from chambers of commerce and other bodies of inadequate trunk communication between important centres of commercial activity are constantly being recorded, and with every justice. Glasgow and Paisley are only six miles apart, and ought really to be in the same telephone area, and not separated by trunk lines. The number of trunks between them is entirely inadequate, and long waits of anything up to 40 or 50 minutes are common. The state of matters between Glasgow and Edinburgh is even worse. Brighton and London is another case in point—in fact, prompt trunk connection between busy centres is often impossible, and can never be reckoned upon. Had Paisley been one of the places in the Glasgow telephone area permissible for the Glasgow Corporation to deal with, that body would have laid an underground cable containing 100 circuits all the way, and so provided for efficient connection between the two towns. In some cases the Post Office duplex the trunk lines, making two lines serve for three simultaneous talks. This is cheap but bad, as the least fault on any of the wires concerned throws the whole out of gear, and conversations are overheard by people for whom they are not intended.

This is a brief sketch of the outcome of the first purchase negotiated by the Post Office. Compared with what is now contemplated, it was quite a twopenny-halfpenny transaction. What guarantee have the public that the same errors will not be repeated on a more gigantic scale? The danger of such a disaster is far from remote, but leaving that point for the moment, let us enquire how, supposing the purchase to have been decided upon, the price to be paid may be ascertained. The methods open to negotiators appear to be three in number: (1) the market value of the shares; (2) the book cost of the system; (3) "tramway terms"—*i.e.*, buy only what is actually required by the Post Office at a fair valuation considered as plant only, giving nothing for goodwill.

The first appears to me quite out of the question. When prospective purchase was announced the preferred shares rose to 108-9, and the deferred to 102: on what grounds or expectations it is difficult to imagine, the spirit of gambling apart. The ordinary shares have been split at least once; on many of them nothing was ever paid up, they being given away for patents long since expired though never written off, promotion, purchase of competing concerns, etc. Yet many people have bought into the company on these terms in expectation of making a profit out of the projected purchase. They must be either very well or very ill informed. Such a deal is simply inconceivable.

Not much more practical is the second method. The book cost will cover plant already scrapped and done away with, and much that is rapidly approaching that stage, as well as the fancy prices paid for the old competing systems. Purchase on these terms would mean an exact repetition of the trunk-line fiasco.

The third or "tramway terms" method would be fair, and, if it can be shown to be compatible with cheap rates, probably acceptable, *except to the sellers*. This fact, doubt about the outcome as regards future rates, and the difficulty, practically insurmountable, of giving effect to it in time to be of service to the nation, will, in my opinion, make it equally impossible with the other two. It must be remembered that the National Telephone Company are not under any obligation to sell unless they like. The Post Office having failed to give notice by June 30 to avail themselves of the last break in the license, all power of compulsion is over, and the two parties meet on equal terms to make a bargain or disagree just as they may decide. Is it likely, therefore, that the National Telephone Company can consent to sell on any such terms? Even if the directors were bold enough to recommend it, the shareholders would not agree. Where would the profit of those who have bought in at 108 or so be? Instead of a profit, the transaction would probably mean the writing off of a large proportion of the share value because the arbitrator could not give cost price, much less a premium, for old plant. He would have to knock off depreciation and, perhaps, obsolescence, and what would remain would certainly not be accepted by the company. Very likely some of the plant would not be purchased at all. From the company's point of view "tramway terms" are impracticable, from which fact may

Digitized by Google

be deduced the generalisation that anything that the company *would* accept would be an astonishingly bad bargain for the country.

Let us now look at the matter as taxpayers and telephone users. Why does the Post Office want to buy the telephones? Is it to benefit telephone users, give them lower rates, and improve and extend the service? Only on some such grounds can purchase be justified at all. But the Post Office record, as I have shown, qualifies it but poorly for the playing of any such important part. The trunk lines speak eloquently as to that. The Post Office is not a reforming institution: it is neither progressive nor sympathetic with public needs and ideals. Its idea of work is to do nothing till forced, and then to leave off again as soon as may be. Can it be trusted to make a bargain for the benefit of the people? Not at all, in my opinion. If left to itself it will probably recommend Parliament to buy at a price which will make cheap telephones simply an impossibility ever afterwards, or, alternatively, will land the country into a standing deficit on telephones as bad as, or worse than, the standing deficit on telegraphs.

It is true that a Select Committee has been promised, but this may mean anything or nothing, according to the terms of reference. On a former occasion—the trunk-line purchase—it must be remembered that the Postmaster-General repeatedly promised that the House would be afforded an opportunity of discussing the agreement before signature, but that ultimately it was laid on the table with the intimation that the Government were pledged to it, and no amount of discussion could alter it one iota. And so the House was jockeyed and the people's birthright sold. What has happened once may well come about again. It is significant that the *Nottingham Daily Guardian* of Dec. 26 and the *Darlington North Star* of Dec. 28 both speak of the agreement as concluded, and of the company as having already incurred considerable expense in anticipation of transfer at the request of the Post Office. Are the shady manœuvres of 1892 to be repeated?

The people's part is to make quite sure *in advance* that no foolish contract is entered into. What is wanted are cheap rates such as are charged by the British corporations who own telephone systems, by the National Telephone Company itself wherever it is face to face with competition, by the Continental telephone administrations, and by the independent telephone companies in the United States. All these show that a rate of between £5 and £6 per annum for an exclusive direct line to the exchange with unlimited calls is remunerative, and that is what must be insisted on in this country. If the Post Office cannot pledge itself to that in advance, then it has no right to buy the telephones. It is no use fixing a price and then discovering too late that, in order to earn interest on it, a rate of £8 or £10 a year must be charged. The business way is to calculate beforehand the maximum sum that is admissible on the basis of, say, a £5. 10s. rate, and if the company will not take it, drop the matter once and for all until the flux of time gives again the right to buy compulsorily by arbitration. But the price must be a very low one because, as was the case with the trunk lines, quite as much as the Post Office gives for the *plant will have to be expended in order to bring it up to date.* When this is thoroughly realised purchase will appear more than ever impracticable. If no purchase is effected the company will remain free till Dec. 31, 1911. If, in the six intervening years, the corporations be encouraged to start competing exchanges, the company will then be found in a much more lamb-like and amenable frame of mind, and telephone users will be in possession of both cheap rates and improved service, because competition and emulation will have produced their usual beneficial effects.

Another and very cogent argument against Post Office purchase is the inability of the Department to find the money for extensions. Few realise to what an extent the telephone system of the country is bound to grow within the next few years, or how many millions of pounds will have to be expended in order to keep pace with the demand. The Post Office depends on the Treasury for its supplies, and the Treasury is often unwilling to oblige. It may have guns to provide, new ships to build, many matters apparently more pressing than telephones to finance, and it will bid the Post Office "go whistle." This has happened already many times in respect to trunk-line construction, and at least once since the Post Office started its London telephone system. Last year for several months it had no money to join up subscribers with or construct trunk lines. Is the telephone system of the country to be hampered in this way for ever? The fact that the demand for money for telephone extensions will be both heavy and incessant and will be resented by the Treasury, is a factor that must not be overlooked.

There is another and extremely important phase of the question which I have left to the last. Hitherto I have written on the assumption that the parties are really serious on the subject of purchase. But is it quite certain that this is the case? The writers and organs identified with the National Telephone Company's interests have recently been arguing against purchase, urging that the company should be left alone till 1911. With a keen appreciation of who provides the real opposition to the company, these articles also plead that no more licenses shall be issued to corporations—but that by the way. It is quite possible that the company has no intention of selling at all—I have shown that it can only do so at a loss—and that the plan is to amuse the Post Office with negotiations, luring it on week by week, month by month, and year by year by an apparent prospect of clinching a bargain, but never reaching that point. If all this time the Post Office declines to issue any more licenses to corporations on the plea that it is negotiating for the nationalisation of the telephones (it has already practically refused a license to Bournemouth Corporation on this ground), it is quite within the bounds of possibility that the parties will find themselves so close to 1911 that there will be no time left for the corporations or anybody to start effective opposition, and then the company's most probable game—prolongation of its license and not purchase—will be won, and the public diddled once more. Once past the stage at which effective opposition may be set up, the Post Office must either buy the company, as provided in the license (which cannot be done in 1911 any more than in 1905, without making cheap rates impossible), or prolong its license. The moral of it all is that monopoly is bad, and that there ought to have been free trade in telephones from the very beginning. The remedy lies in adopting loyally and freely the recommendations of Mr. Hanbury's Committee, and encouraging the corporations to compete, for the only effective opposition which the company has ever met has proceeded from them. No dawdling negotiations should be permitted. If, when Parliament meets, the Postmaster-General is not prepared with a scheme, the idea of purchase should be shelved and the cudgels of opposition given the fullest play.

The eagerness displayed to sell the telephones to the Post Office constitutes a thorough exposure of the hollowness of the outcry against municipal telephone undertakings as being destructive of private enterprise. What is the Government but an exaggerated municipality labouring under the disadvantage of slow, uncertain, and ponderous procedure, with the further disability of not understanding the requirements of specific localities; and what becomes of private enterprise once the telephones are transferred to it? It is extinguished, of course.

---

**Electrical Exhibition.**—The Lighting Committee of the Islington Borough Council propose holding an electrical exhibition at the Hornsey-road baths from Feb. 27 to March 11 inclusive, provided the Council at its meeting to-day approve the scheme. We understand that the three largest baths will be utilised for the exhibition, which will include not only machinery in motion and all kinds of electric lighting, heating, cooking, and power appliances, but also electrical novelties of all kinds, electric fountains, illuminations, etc.; while the men's large first-class bath will be used for swimming and diving entertainments, model yacht races, trips on electric boats, musical entertainments, etc. The idea is to not only attract intending consumers, but also the general public, thereby greatly increasing the value of the exhibition to the exhibitors as a medium of advertisement.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### MOVING-IRON INSTRUMENTS AS AFFECTED BY THEIR "MAGNETIC HISTORY."

SIR,—In view of the interesting figures given by Mr. G. F. C. Searle in his recent paper before the Institution of Electrical Engineers, it occurred to us to investigate the possible error introduced into the readings of moving-iron ammeters and voltmeters working at low magnetic inductions.

It is well known that for many reasons it is of great importance to keep down the induction in instruments of this description when used for alternating currents, but it appeared possible that in the case of direct-current instruments the low inductions employed might introduce errors due to varying "magnetic histories." To determine this point, a low-reading "Universal" moving-iron ammeter was tested, and calibration curves taken under various conditions. It may be noted that the induction in the moving iron in these instruments is kept exceptionally low so as to avoid frequency errors when used with alternating current; hence it was thought possible that the readings might be affected by a direct-current overload.

In the first place, the instrument was thoroughly demagnetised, and a set of up-readings taken. It was then again demagnetised, and a downward curve obtained. After this the instrument was overloaded to the extent of some 700 per cent., and another upward and downward curve obtained. It was found that the mean difference in the reading, brought about by this exceptionally drastic treatment, was as follows: at full load, ·5 per cent.; at two-thirds full load, ·1 per cent.; at one-third full load, ·6 per cent.

It will thus be seen that the influence of the previous "magnetic history" can for all practical purposes be entirely neglected in this type of instrument as manufactured by us.

Yours, etc, EVERETT, EDGCUMBE, AND CO.

### THE METRIC FALLACY.

SIR,—In your issue of Dec. 2 you publish an article on the "Metric Fallacy," on which, with your permission, I should like to make one or two comments.

The question is emphatically *not* one between scientific men on the one hand and practical men on the other. It is true that the Decimal Association is supported by the majority of scientific men in this country, but names such as Sir William Preece, Lord Kelvin, Sir Andrew Noble, Sir Guildford Molesworth (president of the Institution of Civil Engineers), Mr. Alex. Siemens (president of the Institution of Electrical Engineers), Sir Alfred L. Jones, Sir Hiram Maxim, Sir Douglas Fox, Sir Benjamin Baker, Lord Avebury, and Sir Wm. Ramsay, do not suggest mere professors and students of abstract science. We have to deal, in fact, with an agitation by practical men for a scientific system of weights and measures for, as your article well puts it, the simplification of work and the getting of business.

It is true that Sir Frederick Bramwell maintained the superiority of the existing system of British weights and measures over the "much-belauded metric system," and it is not a little curious that the British Weights and Measures Association should be so soon formed for the purpose of standardising and simplifying this British system. Let me quote from their manifesto what they say of our weights and measures: "To architects and builders this confusion of quantities is most vexatious and productive of misunderstandings, loss of time and money. Similar absurdities exist in other trades."

If the contentions of Sir Frederick Bramwell are carefully considered it will be found that he was protesting, not against the metric system, but against the compulsory use of decimals to the exclusion of vulgar fractions. A great deal is made of the contention that in France the metric system has not entirely ousted all the old measures, and this is taken as an argument against the superiority of that system. It is true that in some parts of France the *names* of old weights and measures are still used, but they are old names applied to metric measures. I think, however, that these arguments are beside the point. Our present system has been legalised in the British Islands for about 80 years, and yet we have a list of about 50 "customary," or illegal, weights and measures still in use in this country. Is this to be taken as an additional argument against the British system of weights and measures?

The American author referred to in the article appears to prove that Americans have no need of the metric system, and are content with our existing system of weights and measures. Let your readers judge for themselves. Within the last few years the United States have adopted a ton of 2,000lb., and have adopted a yard derived from the metre. This will show whether present-day business needs tend in the direction of decimalised weights and measures, in harmony with our universal scale of notation, or not.

The concluding part of the article on the metric fallacy contains a curiously inaccurate deduction—"the Latin races against the Anglo-Saxon." Does the writer think that Germany, Holland, Norway, and Sweden are of no account, or that they belong to the Latin races?

The majority of nations have adopted the metric system, and even America is no longer with us, inasmuch as, besides deriving her yard from the metre, and her pound from the kilogramme, the U.S.A. gallon, quart, and pint are all one-fifth smaller than our present ones.—Yours, etc,

E. JOHNSON, Secretary, the Decimal Association.

## FORTHCOMING EVENTS

MONDAY, JAN. 9.

**Institution of Mechanical Engineers (Graduates' Section).**—Paper on "A Mechanical Method of Discharging and Storing Grain," by Mr. A. O. Laird.

TUESDAY, JAN. 10.

**Institution of Civil Engineers.**—(And the 11th).—At 8 p.m., Sir W. H. White will deliver an address, entitled "The Recent Visit to the United States and Canada."

**Institution of Electrical Engineers (Glasgow Section).**—At 8 p.m., "Street-Lighting by Electric Arc Lamps," by Mr. H. B. Maxwell.

THURSDAY, JAN. 12.

**Institution of Electrical Engineers.**—At 8 p.m., resumed discussion on Mr. Adams's paper, "The Combination of Dust Destructors and Electricity Works Economically Considered," and, time permitting, Mr. W. H. Booth and Mr. J. B. C. Kershaw will present a paper on "Fuel Economy in Generating Stations."

FRIDAY, JAN. 13.

**Tramways and Light Railways Association.**—At 8 p.m., "Overhead Equipment," by Mr. H. M. Sayers.

**Junior Institution of Engineers.**—At 8 p.m., "The Theory of the Incandescent Mantle," by Prof. Vivian B. Lewes.

**Institution of Electrical Engineers (Manchester Students Section).**—"Electric Heating," by Mr. A. E. Jepson.

**Institution of Civil Engineers (Students' Section).**—"Theory of Electricity and Magnetism," by Mr. J. Swinburne.

Jan. 27.—The following papers will be read at the Physical Society: "Action of a Magnetic Field on the Discharge through a Gas," by Dr. R. S. Willows; "Action of Radium on the Electric Spark," by Dr. Willows and Mr. J. Peck; "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

## PERSONAL.

The Worcester City Council have appointed Mr. Cyril M. Shaw, of Wakefield, electrical engineer to the Corporation, at a salary of £400, rising by annual increments to £500.

The Bridgend Urban District Council have accepted the resignation of Mr. F. C. Williams, electrical engineer, who has received an important appointment in Natal.

Mr. A. A. Blackburn, A.M.I.E.E., car-shed superintendent of the Manchester Corporation tramways, has been appointed to the position of car-works superintendent to the Belfast Corporation tramways, at a commencing salary of £300 per annum. Mr. Blackburn has been with the Manchester Corporation tramways for 2½ years. He takes up his new duties on Feb. 1, 1905.

On the occasion of the transfer of the Belfast Street Tramways to the Corporation, Mr. Andrew Nance, the general manager of the system for the past 23 years, was presented by the staff and

Digitized by Google

employés with his portrait, painted by Mr. Harry Douglas, and with an address in album form from the conductors and drivers, while Mrs. Nance received three massive solid silver rose bowls with suitable inscriptions, accompanied by a beautifully illuminated address to Mr. Nance from the more prominent officials.

Mr. Harold W. Seymour has been appointed car-shed superintendent to the Blackburn tramways department.

Mr. E. Banner has been appointed clerk of the works for the extension of the Derby electrical tramways from St. Peter's street to the Market-place, and for the construction of a cross-over in Victoria-street, at a salary of £3. 10s. per week.

## APPOINTMENTS VACANT.

**Electrical Engineer**, Hanley Corporation. Salary £300, rising to £350 by annual increments of £10. Applications to Town Clerk by Jan. 10

**Junior Assistant**, King's Lynn. Commencing salary, £65 per annum. Applications to Borough Electrical Engineer by Jan. 7. See advertisement in last issue.

**Assistant in Charge of Meter Department**, Hammersmith. Commencing salary, £2. 10s. per week. Applications by Jan. 18. See advertisement.

**Three Electrical Engineering Assistants**, City and Guilds Central Technical College. Salaries commencing respectively at £200, £150, and £150 per annum. Apply to Prof. Ayrton, Exhibition-road, London, S.W. See advertisement.

**Second Assistant Electrical Engineer**, Bradford. Salary, £250 per annum. Applications by Jan. 19. See advertisement.

**Improver**, Stretford Urban District Council. No premium required. See advertisement.

**Switchboard Attendants**. Wages, 20s. per week. See advertisement.

**Canvasser** for a municipal borough. See advertisement.

**Switchboard Attendant**, Carlisle electric light and power station. Salary, 25s. per week. Applications to the City Electrical Engineer by Jan. 10. See advertisement.

**Electrical Adviser.** The Secretary of State for India has sanctioned the appointment of an adviser on electrical matters to the Government of India at a salary commencing at £70 per month, rising to £110. Private practice will be allowed, but not for municipalities or district boards, as it will be part of his regular duties to advise such bodies.

## LEGAL INTELLIGENCE.

### OBSTRUCTING THE TRAMS.

Before the Borough Bench, John Padley, carrier, was summoned for driving a horse and cart in Belgrave-road in such a manner as to obstruct an electric tram.

The motorman deposed that on the day named he was going from the Clock Tower to Belgrave, when he noticed defendant, who was driving a carrier's van. The van was on the metals in front of the car. Witness rang the bell very loudly several times, and defendant put his head round the corner of the tilt and laughed at him, saying "Don't be in a hurry, boss." Defendant then drew off, but this was near Melton turn, and witness had to stop to pick up passengers. During this defendant drove in front again, and obstructed him for a considerable distance. Witness then took defendant's name and address, and told him he would be reported.

A passenger corroborated.

In the second case, the motorman of another car said the defendant's van obstructed him for a considerable distance.

Defendant said that as to the first case three cars had just passed, and he did not dream that another was coming so soon. As soon as he heard the gong he drew off on to the road. He did not wilfully obstruct the trams on either occasion.

He was fined 20s. in each case, or 14 days.

## COMPANIES' MEETINGS AND REPORTS

### MANX ELECTRIC RAILWAY.

A meeting of this Company was held on Wednesday at the offices, 78, Cornhill. Particulars of the report appeared in our issue of the 23rd ult.

On the motion of Mr. Ernest Schenk, who presided, the report and accounts were adopted. The net earnings of the year were £13,538, and, after payment of the debenture interest, a dividend of 2½ per cent. on the preference shares, and placing £1,000 to the renewal fund, the balance of £780 was carried forward.

### DOUGLAS SOUTHERN ELECTRIC TRAMWAYS.

The ninth annual general meeting of the shareholders of the Douglas Southern Electric Tramways Company was held on Friday last in Manchester. The report and statement of accounts showed that the Company's season this year consisted of 134 days, as against 123 days last season, whilst the mileage run was 35,075·97, as against 32,343·77 last year. Notwithstanding the splendid summer, there had been a great falling off of visitors, caused by the crisis in the cotton trade, and the Manx season had suffered severely. It was a matter for congratulation that the receipts had kept up very fairly, being only £176 below those of last season. The total receipts this season were £4,785, as against £4,961 in 1903. The net profit for the year was £1,681, as against £1,965 last year, which, added to £209 balance from last year, gave a total disposable balance of £1,890. The directors recommend a dividend of 6 per cent. upon the preference shares, which would absorb £1,558, and leave a balance of £332 to be carried forward, subject to directors' fees. From and after Nov. 1, 1905, an additional payment of 5 per cent. of the gross receipts became due to the Marine Drive Company.

**The Chairman** (Mr. T. J. Hutchinson), in moving the adoption of the report and balance-sheet, said Douglas, like other watering-places to which Lancashire people resorted, had suffered from the depressed state of the cotton trade. The shareholders of that Company might congratulate themselves that under the circumstances the depreciation in their receipts had been trifling. The weather during the summer was of the best, but, unfortunately, the people who usually kept the watering places going had not the money wherewith to enjoy themselves. There was a slight increase in their working expenses, but their equipment generally had been maintained at the highest state of efficiency. The directors recommended the payment of a dividend of 6 per cent. per annum upon the preference shares, and the carrying forward of a balance of £332 to next year's accounts.

**Mr. W. Davenport**, who seconded the resolution, hoped that they would soon be in a position to make some return to the ordinary shareholders.

A **Shareholder** wished to know whether a scheme could not be devised for amalgamating the Southern Electric Tramways and the Marine Drive Companies with a view to the curtailment of expenses.

**The Chairman** said the question with regard to amalgamation was premature.

The resolution was passed.

Mr. W. Davenport was re-elected a director of the Company, and Messrs. E. Guthrie and Co., chartered accountants, Manchester, were reappointed auditors.

## NEW COMPANIES REGISTERED.

**Bergtheil and Young, Limited.**—Messrs. Bergtheil and Young, 12, Camomile-street, E.C., have converted their business into a limited company. The company will take over the business hitherto carried on by them as from Jan. 1, 1905, the following having become directors of the company: Messrs. Arthur Bergtheil, Henry Wilson Young, Edward Bergtheil.

**Tramways Development Company, Limited.**—Capital, £100. Objects: to own tramways, railways, omnibuses, and vans, and to equip, maintain, and work the same by electrical, steam, horse, or other power, etc. No initial public issue. Registered without articles of association.

**Rushworth Bros., Limited.**—Capital, £30,000. Objects: to carry on the business of consulting and mechanical engineers, iron and brass founders, millwrights, brewers' engineers, electrical engineers, plumbers, machinists, boilermakers, manufacturers of and dealers in lifting and hoisting machinery, stone, marble, and granite cutting, working, and polishing machinery, builders' and contractors' plant, hand, steam, and electric cranes, motors, etc. Registered office: Crane Works, Primet Bridge Foundry, Colne.

**John W. Sutcliffe and Co., Limited.**—Capital, £5,000. Objects: to acquire the business carried on at 7, Castle-street, Finsbury, E.C., as Hans Neumann and Co.; to adopt an agreement with A. Peltesohn; to act as manufacturers' agents; to trade in electrical and general supplies; and to carry on the business of electrical, gas, and general engineers, etc.

**Manchester and Milford Engineering Company, Limited.**—Capital, £10,000. Objects: to carry on the business of mechanical engineers, ironfounders, ironworkers, tramcar, motorcar, locomotive, and rolling-stock manufacturers, makers of signalling apparatus, telegraphs, telephones, etc. Registered office: 22, Conduit-place, Spring-street, Paddington.

**Herbert Plumpton, Limited.**—Capital, £6,000. Objects: to acquire the business and carry on at the Excelsior Toolworks, Liverpool-road, Warrington, the business of tool manufacturers, engineers, ironmasters, wire-drawers, galvanisers, iron and brass founders, electrical engineers, electric cable manufacturers, coppersmiths, electricians, suppliers of electricity for light, heat, power, or otherwise, electric and other car manufacturers, etc. Registered office: Samuel-street, Warrington.

**Meadows, Teeton, and Minshall, Limited.**—Capital, £1,000. Objects: to acquire and carry on the business of W. A. Meadows and H. W. Teeton, as Meadows and Teeton, at 7-9, Albion-street, Hanley, as electrical and mechanical engineers, manufacturers of and dealers in electrical, magnetic, telegraphic, telephonic, and other appliances, suppliers of electricity, manufacturers of electric lamps and fittings, etc. Registered office: 7, Albion-street, Hanley.

**New British Electric Supply Company, Limited.**—Capital, £2,000. Objects: to acquire the business of electrical manufacturers recently carried on by the New British Engineering Company, Limited; to adopt an agreement with Bergtheil and Young; and to carry on the business of electrical and mechanical engineers, suppliers of electricity, manufacturers of and dealers in all kinds of electric, magnetic, galvanic, chemical, and other appliances, etc.

**Mors, Limited.**—Capital, £15,000. Objects: to acquire English patents relating to motorcars of the Société Anonyme d'Electricité et d'Automobiles Mors or others; to manufacture and sell in the United

Digitized by Google

Kingdom and British colonies and dependencies motor-boats and accessories in accordance with such patents; to deal in motorcars and accessories made by the Compagnie Française des Voitures Electromobiles, and to carry on the business of garage proprietors, motorcar and vehicle manufacturers, agents and merchants, electrical and general engineers, etc. Registered office: 55-59, Shaftesbury-avenue, W.C.

### Liens Registered.

**North-West London Electric Supply Company, Limited, London, E.C.**—Trust deed dated Dec. 7, 1904, registered Dec. 22, for securing £20,000 debentures (£10,000 issued). Trustees: A. H. P. Strickland and P. A. M. Hoare, bankers, 37, Fleet-street, E.C. Charged on the undertaking and all the property, including the uncalled capital.

**Newcastle and District Electric Lighting Company, Limited.** Issue on Dec. 16 of a 4 per cent. debenture for £25,000, part of a series created Jan. 30, 1903, to secure not more than half the paid-up capital. Property charged: the company's undertaking and property, present and future, except uncalled or unpaid capital (as a first and floating security). Holders: Lloyds Bank Limited, Lombard-street, E.C. No trustees. Total amount previously issued of same series, £11,085.

**Bath Electric Tramways, Limited, London, E.C.**—Trust deed registered Dec. 13, for £135,000 debenture stock. Trustees: Sir F. L. Robinson, of Campden-hill, S.W., and H. P. Sturgis, of Leatherhead. Charged on the tramway undertaking and all other assets, present and future, including the uncalled or unpaid capital.

**Buenos Ayres Grand National Tramways Company, Limited.** A trust deed, dated Dec. 9, 1904, supplemental to a trust deed of Feb. 16, 1900, securing £700,000 conversion debenture stock (which includes £100,000 second preference debenture stock covered by the principal trust deeds, to be exchanged under the terms of the present deed for the same amount of conversion debenture stock), has been registered. Dates of resolutions authorising series—March 6, 1903 (shareholders and 6 per cent. debenture holders), and March 11, 1904 (second preference debenture stockholders and Board). Property charged: the company's undertaking and all its concessions, lands, tramways, premises, and property in the Argentine Republic. Trustees: the Trustees, Executors, and Securities Insurance Corporation, Limited, Winchester House, Old Broad-street, E.C.

**Electric Law Press, Limited (London).**—Issue on Dec. 8 of £200 7 per cent. debentures, part of a series created by resolutions of June 23 and Sept. 30, 1903, to secure £500, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £240.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Halifax.**—The Corporation invite tenders for coal conveyors. Tenders by Jan. 31.

**Paris.**—The Under-Secretary for Post and Telegraphs, 103, Rue de Grenelle, requires tenders for accumulator batteries. Tenders by Jan. 18.

**Algiers.**—Tenders are required for the erection of an electrical plant at the Abd-el-Kader Fort at Bougie. Tenders to the Mayor of that place by Jan. 17.

**Giurgu (Roumania).**—Tenders are required for a concession to establish electric lighting in the town. Particulars may be obtained from the Mayor. Tenders by Jan. 28.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Caen (France).**—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1.

**Completion of Works.**—A local authority in possession of powers for the electric lighting of its area is open to negotiate with suitable persons for the execution and completion of the works. See advertisement in last issue.

**Grimsby.**—The Corporation invite tenders for (No. 30) motors; (31) water-purifying plant; and (32) 12 months' supply of stores. Tenders for 30 and 31 by Jan. 23, those for 32 by Feb. 1. Particulars in advertisement columns.

**Bradford.**—The Education Committee invite tenders for the lighting of the Dudley-hill new Council Schools by electricity. Tenders to Mr. Tho. Garbutt, secretary, Education Offices, Manor-row, Bradford, by 10 a.m. on 9th inst.

**Port Elizabeth.**—Messrs. Davis and Soper, 54, St. Mary-axe, E.C., agents of the Municipal Corporation of Port Elizabeth, South Africa, invite tenders for various works in connection with the Corporation electricity supply undertaking. Tenders by Jan. 16, 1905.

**Erith.**—The Urban District Council invite tenders for overhead line equipment, poles, etc.; underground feeder cables, boxes, etc.; rotary converters, transformers, and motor-booster; and main high and low tension switchboards, cable connections, etc. Tenders by Jan. 9.

**Pudsey.**—The Corporation invite tenders for underground electric mains, switchboard, etc. Specifications, etc., may be obtained on application to Messrs. Shepherd and Watney, consulting engineers, Greek-street-chambers, Leeds. Tenders to the Town Clerk by Jan. 20.

**Gravesend.**—The Education Committee invite tenders for the electric lighting of King-street National School. Specification and form of tender may be obtained on application to Mr. C. F. McInnes, Electricity Works. Tenders to Mr. H. H. Brown, town clerk, by 16th inst.

**London, N.**—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Northern Hospital, Winchmore Hill, N., in accordance with plan and specification prepared by Mr. W. T. Hatch, M.I.C.E., M.I.M.E., engineer-in-chief. Tenders by 10 a.m. on Jan. 24.

**Swindon.**—The Corporation invite tenders for the supply and erection of one 30ft. by 8ft. Lancashire boiler with down-take superheater, steam, exhaust, and feed piping, etc. Tenders to be delivered before 10 a.m. on Tuesday, Jan. 24, 1905, to Mr. Robt. Hilton, town clerk. See advertisement in last issue.

**Ormskirk (Lancs.).**—The Guardians invite tenders for the necessary apparatus for electric lighting at their workhouse, Wigan-road. (Section 1) steam exhaust, &c., piping and erection of plant; (2) booster; (3) storage battery; (4) wiring of buildings and underground cables. Tenders to Mr. Alfred Dickinson, clerk, Railway-road, Ormskirk, by 9 a.m. on 12th inst.

**Drax (near Selby).**—Tenders are invited for electric light installation, also electric pump, etc., capable of delivering 500 gallons per hour, at Read's Grammar School. Apply to the headmaster, Mr. W. St. G. Drennan, at the School, who will supply all necessary particulars. Tenders to be delivered to Messrs. E. and T. Clark, solicitors, Snaith, R.S.O., clerk to the Governors, by noon on 28th inst.

**Johannesburg.**—The Council invite tenders for Vignoles rails, fishplates, angle steel guard-rails, bolts, nuts, coach screws, and dog-spikes. General conditions, specifications, and forms of tender may be seen at the offices of the Council's consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and may be obtained on payment of five guineas. Tenders by Jan. 26.

**South London Electric Supply Corporation.**—The Directors invite tenders for the construction, supply, and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of one 750-kw. steam alternator with pipe connections and sundry ironwork. Sealed tenders must be forwarded to the secretary of the company, Mr. H. H. Boyer, Bengeworth-road, Loughborough Junction, S.E., before noon on Jan. 16.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**Plasencia.**—Tenders are required for the concession for 10 years of the lighting by electricity of the town. Adjudication of tenders will take place on Jan. 28, and tenderers, if not appearing in person, must be represented by a duly authorised agent. The conditions of concession are set out in the notice in the *Gaceta*, which may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

**Copenhagen.**—The Public Lighting Office of Copenhagen invite tenders for the installation of a central electrical station at the Valley gasworks in accordance with conditions and drawings which can be inspected at the Ostre and Valley Gasworks, or obtained therefrom on payment of £1. 2s. 3d., which will be returned provided a tender is sent in in due time, accompanied by the drawings, etc. Tenders must be sent in to the Director for Public Lighting, 22B, Vestre Boulevard, Copenhagen, by noon on Jan. 23.

**Melbourne.**—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

### RESULTS OF TENDERS.

**Aberdeen.**—The Town Council have accepted the tender of Messrs. Babcock and Willcox for shifting boilers at Cotton-street and fitting them with chain-grate stokers, etc., at £870.

**St. Andrews.**—The power station having been completed, the Electric Supply Association have now begun to lay their electric cable. The Lighting Committee of the Town Council are negotiating for the laying of a special cable with the view of eventually adopting electricity for street-lighting.

# BUSINESS NOTES.

## TRACTION.

**Derby.**—The contractors have promised to complete the Market-place route by the 17th prox.

**Lancaster.**—The Electricity Committee are considering the advisability of establishing a motor omnibus service.

**Newcastle.**—The Tramways Committee have decided to recommend the Corporation to proceed with the Shieldfield extension.

**Eastbourne.**—An enquiry has been held into the application of the Town Council for a loan of £1,850 for two additional motor 'buses.

**Ilford.**—Referring to our note last week, it has been decided to put by half the profits year by year and devote the other half to the general rate.

**Perth.**—The Corporation have received sanction from the Secretary for Scotland to the raising of a loan to defray the cost of the additional plant at the electricity works for supplying power for the tramway.

**Musselburgh.**—The controversy upon Sunday running has led to a tentative arrangement, the Corporation giving their sanction for one year, on the expiration of which they will be guided by the experience gained during that period.

**Bath.**—The directors of the Bath Electric Tramways, Limited, have declared a dividend at the rate of 5 per cent. per annum upon the cumulative preference shares, calculated from the due dates of the various instalments to Dec. 31, 1903.

**Halifax.**—The Corporation are about to resume the direction of its parcel traffic, which for the past two years has been undertaken by a contractor. Telephones are to be installed at each 1d. stage to facilitate communication with headquarters, the estimated cost being £550.

**The Metropolitan.**—The electric service from Baker-street to Harrow was successfully inaugurated on Saturday. The first train ran from Baker-street at 8.35, and the last at 5.34. There will still be steam trains running on the line until the whole has been electrified, but in the course of a few days the majority of the trains will be electrically driven.

**South Shields.**—The Tramways Committee having had under consideration the replies received from 62 towns as to whether the work of constructing the lines had been carried out by contract or by workmen employed by the Corporation direct, the committee decided to adhere to their resolution, recommending the Council to advertise for tenders, and this has been approved by the Corporation.

**Crewe.**—Several promoters are suitors for the privilege of installing a tramway, and as the Corporation expect to make a good thing out of it by supplying the current, they will probably approve one of the schemes; but they have informed Dr. Rhodes, of Manchester, who asked the Council to support a private electric tramway company, and Mr. S. Jackson, who offered to promote a service of steam motor omnibuses, that the Council cannot give their sanction.

**Kirkcaldy.**—At the meeting of the District Committee on Saturday the Wemyss tramway provisional order was approved. Petitions in support of the scheme were read from the adjoining burghs. The tramways are to cover a distance of about eight miles from Kirkcaldy to Leven, and only about two miles will be on the public road, the remainder being within the domains of Mr. Wemyss, of Wemyss Castle. Private enterprise is responsible for the undertaking.

**Maidstone.**—The Corporation adopted the following resolution after considerable discussion: "That the sum of £25,000, authorised to be raised by Section 73 (1) of the Maidstone Corporation Light Railways Order, 1903, be borrowed from the Royal Insurance Company, repayable within a period of 40 years by equal yearly instalments, the rate of interest to be £4 per annum, payable on the outstanding balance of principal due, and that the common seal of the Corporation be affixed to the mortgage deed."

**Radcliffe.**—The Radcliffe New-road section of the Radcliffe tramways system, which was completed and formally inspected on Tuesday, was opened for traffic on Wednesday. Two decorated cars left Whitefield with members and officials of the town councils interested. The destination of the car was Radcliffe Bridge, and there was a large crowd awaiting its arrival. This length of track will give through travelling facilities from Radcliffe to Bury, Manchester, and Salford. The Bury Corporation supply the service of cars, and the Radcliffe Council the current.

**Central London Railway.**—A breakdown at the Bank Station on Wednesday occasioned considerable inconvenience. The mishap occurred through the motor of an empty train, which was being shunted from one road to another, leaving the metals at the cross-over. Some difficulty was experienced in replacing the engine on the track, and for some time no trains ran beyond the Museum Station, where the next shunting place is situated, the 'buses reaping a harvest during the interval. The whole line was cleared, however, in time for the homeward rush in the early evening.

**Electrical Machinery for Japan.**—Last week a special train consisting of 42 wagons left Dick, Kerr, and Co.'s Preston works, carrying 250 tons of electrical machinery being shipped in connection with that company's contract for the complete equipment of the Tokyo Denki Tetsudo Kabushiki Company's tramways. This tramway system, when finished, will cover over 60 miles of line and operate some 250 cars. The complete installation is being carried out by Dick, Kerr, and Co., under the supervision of a staff of their engineers, and it is surprising to learn that the only effect the war has had on the progress of the work is in connection with the transportation of the machinery from Yokohama to Tokyo, the railway being congested with war material.

**Mexborough and Swinton.**—The Mexborough and Swinton Tramways Company, which was incorporated in 1902, has deposited a Bill for next session, under which Parliament will be asked to grant an extension of time for three years from Aug. 8, 1905, within which to complete the tramways duly authorised. This extension of time extends to the tramways authorised in the urban districts of Rawmarsh and Greasborough, which were sanctioned by the Rawmarsh Urban District Council (Tramways) Act, 1900, whose powers have been transferred to the company. The Bill also proposes to empower the company to issue "any portion not exceeding £75,000 of their authorised capital of £150,000 as preference shares," bearing interest at 6 per cent. per annum.

**Belfast.**—In connection with the formal handing over of the tramways undertaking by the company to the Corporation, a luncheon was given to several members of the Corporation and officials of the company by the directors in the Grand Central Hotel on Saturday afternoon, when complimentary speeches were exchanged. Mr. J. Barber Glenn (secretary of the company) took a philosophical view of the transfer, remarking that when the time allotted by the Act for handing over the undertaking came it was worse than useless to repine, and as he had to part with the control of the system to the municipality, he cordially did so, and wished them all possible success. He believed that under the administration of their committee, presided over by so experienced a business man as Sir Daniel Dixon, and with the invaluable help of the manager (Mr. Nance), they could not avoid achieving success.

**Aberdare.**—On Monday a statutory meeting of the Urban District Council was held to pass a resolution in support of the parliamentary Bill for the construction of an electric tramway from Trecynon to Cwmaman and Capcoch and the erection of a refuse destructor. Mr. E. M. Hann, general manager of the Powell Duffryn Collieries Company, and chairman of the Parliamentary Committee, moved the formal resolution in favour of the Bill. He explained that the discrepancy in the original figure of £62,000 and the present figure of £93,000 was due to additional schemes having been included in the Bill, apart from the tramway. There is also the extension to Capcoch, the cost of which will be £6,000. The bridge at Aberaman and the diversion of the road would have to be carried out apart altogether from the present scheme. The cost of this had been put down at £5,116, but of this the County Council and the Powell Duffryn Company would pay £3,336. After some discussion the motion was carried, and the scheme will now be proceeded with, subject to the sanction of a public meeting.

**Fire and Water Proof Dynamos.**—The following incident, which occurred recently in the United States, testifies to the extent to which modern well-made electrical machinery will stand ill-usage. The New England Building at Cleveland, Ohio, is electrically lit throughout by a plant consisting of three Westinghouse 62·5 kw. engine-type generators, installed in the basement, which, through some carelessness, recently became the scene of a rather serious fire. The heat to which the machines were subjected was sufficient to completely burn away the insulation on the outside of the field coils, and for an hour they were played upon by six hose pipes. Within an hour of the extinction of the fire the first of these machines was carrying its full load, and another followed suit in a short time, the two dealing with the entire lighting of the building, that under normal conditions was negotiated with three machines. With the exception of the outer layer on the field coils, which was burnt away, the insulation was fireproof, and easily withstood a heat that was sufficient to burn and blister the paint on the frames. The two elements most fatal to electrical machinery were thus resisted in a manner quite beyond expectation, which speaks eloquently for the quality of the manufacture.

**Motorcars.**—A writer in the *Manchester Guardian* thus sums up the position of the British motorcar industry: "The British motorcar maker is a little too apt to assert that if only the British investor would move capital all would be well. It is possible that in the later phases of development the industry has been hampered by want of capital, but capital will be forthcoming when we pass from the stage of the pleasure car to the more permanent and more remunerative industrial car. A pleasure car is subject to the whims of fashion, and is no way a sure guide to the future. The fluctuations in the trade done by various motorcar manufacturers demonstrate this. But the moment when industrial motorcars become practicable and economical, we may rest assured that the British investor will be equal to the occasion. At all events, the rise of the British motorcar industry during the past five years is one of the most striking events in contemporary commercial history. There are as yet a good many loose ends to be drawn in, and more effective combined action on the part of the makers is desirable, but the growth, such as it is, reflects the greatest credit upon British makers. The Comte De Dion said in 1896: 'We (the French) have got this trade, and we mean to keep it. It is of no use your trying. You may try, but you will never beat us.' All honour to the French and German makers for what they have done. We are not jealous of their success. Our congratulations are hearty and sincere. But the British engineer, the British mechanic, and the British business man, when once they have taken hold of an industry in earnest, do not easily let go. The motorcar industry of Great Britain has come to stay; it is growing rapidly; year by year it extends its activities in new directions; its future is bright; and under our present system of free trade it has the world's market at its disposal."

**Westinghouse Turbine.**—A memorable incident of the morning following the close of the St. Louis Exposition was the formal shutdown and inspection of the 600-h.p. Westinghouse steam-turbine generating unit in the Palace of Machinery, after a continuous run of over 3,962 hours—a remarkable performance in the history of the steam-turbine. This machine was started on its long run at 9.20 o'clock on the morning of Monday, June 20, shortly after its installation at the Fair, and was stopped at 11.32 o'clock on the morning

Digitized by Google

of Friday, Dec. 2. During the 5½ months that the unit was in operation it supplied current for light and power throughout the Westinghouse exhibits in the Palaces of Machinery, Electricity, and Transportation. Mr. C. F. Foster, chief operating engineer of the Exposition, Mr. H. M. Holman, supervising engineer at the Government Exposition gas engine tests, formerly president of the St. Louis Board of Public Works, and a number of Westinghouse representatives, including Messrs. Wallace Franklin, of Detroit, C. C. Chappelle, of Chicago, and W. K. Dunlap, managing director of the Westinghouse exhibits, were present when the engine was stopped. It was found to be in perfect condition, and there were no signs of wear, the bearings still retaining the tool marks as they had come from the shops. There have been at least two instances on record in America in which piston engines have been run continuously for about the same length of time as that of the record run of the Westinghouse turbine. The remarkable feature of the turbine run, of course, was the maintenance under load of a speed of 3,600 revolutions a minute for such a long period. From 8.30 o'clock in the morning to 10.30 o'clock in the evening, the load carried throughout the Exposition varied from 25 per cent. underload to 25 per cent. overload. The total number of revolutions almost touched the billion mark, according to the American system of notation—viz., 855,792,000.

**London Road Car Co.**—The manager of this company, Mr. Duff, stated to an interviewer the other day that in less than four years he expects motor omnibuses will be running over all the routes at present traversed by the company's vehicles, and other routes as well where steep gradients or other difficulties have rendered horse haulage an impossibility. The change will be begun at once, and will continue until the entire system is converted. It will be carried out as rapidly as possible. Work has already been begun on the first batch of 50 omnibuses, and contracts for the motors and frames have been placed with three English and two Continental firms. The bodies of the vehicles will be built by the company at its own works, where their existing rolling-stock has been constructed. Each motor built will displace about 15 horses. The new vehicles will cover a daily mileage of 100, instead of 70 or 80, as with animal haulage. In less than six months the company expects to have displaced 700 horses A comparison of the cost of running of the two classes of vehicles is in favour of the mechanical method. Repairs will cost less because the body of the car will sit on a solid frame, and not on four springs as now. Mr. Duff intimated his opinion that the cars will be worked as cheaply by petrol as with horses, while he looks for the earning power to be increased by 50 per cent. The latter calculation is based on the experience the company has gained from the experimental running of the four motor omnibuses which have been for some time on the road from Shepherd's Bush to Oxford-circus. Most of the omnibuses which have been already ordered will have a carrying capacity of 32 or 34, as compared with the 26 for which the existing vehicles are designed, but there will also be smaller ones to accommodate 14 passengers without roof seats. These will be used on routes where there may be very steep gradients or where public necessity does not call for the larger car. It is estimated that 350 motor omnibuses will suffice to accommodate the traffic which is now dealt with by the 466 horsed vehicles which the company has daily running, but apart from the reduction in number street congestion will be relieved, as each motor will take up considerably less space than a horsed omnibus. The first of the new vehicles will probably be put on the road about the end of February, and the 50 cars now being built will all be delivered by the end of May. The Shepherd's Bush and Oxford-circus route will be the first favoured.

**Liverpool.**—Under their Bill the Corporation are seeking powers to construct lines of electric tramway from the docks for the conveyance during the daytime of merchandise to various parts of Lancashire on the lines of the South Lancashire Electric Tramways Company. If the necessary permission is granted, it is proposed to construct one of the lines connecting with the docks at the South-end of Liverpool, and the other at Bootle connecting with the North Docks. The Royal Southern Hospital is situated on the route, and it is reported that the proposal has been received with some alarm by those responsible for its management, on the ground that the noise of the traffic would have a detrimental effect upon the patients, and that during the administration of anæsthetics in operations it would be absolutely dangerous. The tramway authorities, on the other hand, state that there is no reason to fear any such annoyance or ill-effects from the proposed service. It is pointed out that it would be impossible to deal with the merchandise from the docks and transship it to various parts of Lancashire during the night-time on the ordinary passenger tramlines. The night traffic would be too costly, and further, there would only be an interval of four hours in which to work the traffic, and as a rule much of the repair work to the lines is carried out during the night-time. As an alternative the tramways authorities are desirous of constructing lines quite apart from the passenger lines to deal with the merchandise from the docks. For years leading Liverpool merchants have agitated for some method by which goods could be transferred straight from the ship in dock to vehicles which would distribute them in the various districts, and thus avoid repeated handlings, with their increased cost, to say nothing of railway delays. Since the advent of that fine service belonging to the South Lancashire Tramways Company this desirable end has been rendered easier of accomplishment. It is considered that once a through connection from the docks to the South Lancashire Company's system at Knotty Ash is made, a new industrial era will begin to open up. The area to be served is an enormous one. The South Lancashire Company's system at present embraces a very extensive mileage of street tramways, tapping all the busy manufacturing centres in the county, like Bolton, Warrington, Leigh, Atherton, Blackburn, etc., and taking into account the connections with other tramway systems bordering on to Yorkshire, there are at present about 700 miles of street tramways over which a goods traffic might be carried on. It is pointed out that land is comparatively cheap in the outskirts, and that it would pay manufacturers to erect works in positions adjacent to the tramways, and where a through connection could be made by means of a short siding for the works. They would thus have the advantage of a cheapened transit of goods, as compared with the present high railway rates. It is not unlikely, if the project is carried through, that the line of railway along the docks will be electrified and joined to the tramway, thus forming a circular system. The Dock Board, it is reported, have given consideration to this question of electrification, and have undertaken to look further into it if a feasible scheme is devised. The vehicles for the new tramways would be merchandise cars of the American type, each constructed to carry 15 or 20 tons.

## LIGHTING AND GENERAL.

**Wimbledon.**—Large extensions to the central-station plant are under consideration.

**Barking.**—Application is to be made for a loan of about £9,000 for electric supply extensions.

**Sale of Plant.**—Particulars of a sale of a 25-h.p. compound undertype engine will be found in another column.

**Shipley.**—The Urban District Council are experimenting with the idea of extending the arc lighting in their streets.

**Finchley.**—The Urban District Council have fitted and opened an electrical showroom at 3, Market parade, East Finchley.

**Halifax.**—About two miles of streets in the centre of the town are lit by electricity, the cost being at the rate of £849 per mile.

**Gloucester.**—The City Council have approved of a scheme for the extension of electric lighting at an estimated cost of £15,000.

**Frizington.**—The Arlecdon and Frizington District Council have asked Mr. Rook, of Workington, to report on the cost of a scheme of electric lighting.

**Removal.**—Messrs. Chas. F. Quicker and Co., electrical, mechanical, and consulting engineers, have removed their offices and stores to 315, Euston-road.

**Hull.**—The street-lighting now consists of 24 arc lamps, 20 ½-ampere Nernst lamps, and 24 ½-ampere Nernst lamps. The arc lamps are of 1,000 c.p., and cost £22 per lamp per annum.

**Tonyrefail.**—The electric lighting undertaking at Tonyrefail was formally inaugurated on Tuesday by Mr. Godfrey Clark, J.P., Talygarn, chairman of the Llantrisant District Council.

**Electric and General Investment Co.**—The warrants for the interim dividends on the 6 per cent. cumulative preference shares and of the 10 per cent. per annum on the ordinary shares of this company have been posted.

**Edmundson's Electricity Corporation.**—The directors have declared an interim dividend of 5 per cent. per annum on the ordinary shares of this company, payable on 14th inst., for the half-year ended Sept. 30, 1904.

**Clyde Valley Power Co.**—The equipment of the generating station at Yoker is nearly completed, and current will probably be shortly available for distribution. The Motherwell generating station will be at work a few months later.

**Shrewsbury.**—The Town Council have agreed to a preliminary expenditure of £508 on extension works in connection with the electric lighting undertaking. The estimated cost of the further extensions will be approximately £5,295.

**Barnstaple.**—The engineer reported at the last Town Council meeting that since the last meeting he had received application for light equal to 155 8-c.p. lamps. It was resolved that application be made for permission to borrow a further sum of £3,000 for the purpose of extension of the lighting.

**Loughborough.**—The Corporation are notifying that they are prepared to supply electrical energy for the purposes of general supply to ordinary consumers in the streets through which distributing mains have been laid. The prices to be charged until otherwise determined are as follows: for lighting, 5d. per unit; and for motive power, 2½d. per unit.

**Rotherham.**—The electric lighting was suspended for two hours recently owing to the fusing of a cable. The electricity department took prompt steps to locate the failure, and just before eight o'clock the service was restored. This is the first occasion an accident of the kind has occurred, although the works have been in operation for about three years.

**Leeds.**—In the course of a few weeks' time the chief tramway thoroughfares for a radius of one mile from the centre of the city will be lighted by electricity in place of gas. The present number of arc lamps will be nearly trebled, and the Corporation propose to reduce on and after March 25 next the prices of electrical energy supplied for lighting purposes to large consumers.

**Kettering.**—The current was switched on for the first time at the Trades Club on Christmas Eve in the presence of several representatives of the Urban Council and members of the club and affiliated bodies. The contract for the wiring was in the hands of Messrs. Thompson and Co., of Wellington-street, Kettering. Altogether 72 lights have been installed with a total power of 18 amperes.

**Dewsbury.**—The users of the telephone in the district are called upon to pay £10 per annum for a similar service to that for which £5 or £6 is charged in other towns where competition with municipal schemes has to be faced, and it is suggested in the local Press that the present area covered by the Dewsbury telephone exchange is large enough to make a local scheme self-supporting.

**Heckmondwike.**—The Urban District Council are making a feature of street electric lighting, the cost being the same as that

Digitized by Google

for gas. About one-third of the street lamps are lighted by electricity, and although there is a diversity of opinion as to whether incandescent gas or electric light is the more effective, so satisfied are the authorities with the arc lamp illumination that they contemplate an extension.—*Yorkshire Post.*

**Arbroath.**—An agreement has been come to between the Arbroath Electric Light Committee and the Empire Electric Lighting Company, Limited, London, with a view to the introduction of the electric light into the town, so that nothing further requires to be done except the execution of the formal deed after it has been approved of by the Board of Trade. The company are to start operations immediately after they obtain possession of the site for the works. The ground will be available on May 28 next.

**Liege Exhibition.**—Further information has now been received from the Association of Chambers of Commerce of the United Kingdom to the effect that, in consequence of applications which have been made by intending exhibitors, the British Commissioner-General is negotiating with the authorities for an extensive increase of space for British exhibits in the machinery hall, and he is, therefore, in a position to receive further applications for the display of machinery in motion. The Commissioner-General is Mr. Thomas Cope, to whom all applications for space should be addressed at the British Commissioner-General's Office, 54, Great Tower-street, London, E.C.

**Grimsby.**—We are informed that, owing to the general satisfaction given by the installation of electric light and power for sterilising and cautery purposes in the operating theatre of the Grimsby and District Hospital, the Management Committee have decided to entrust the lighting of the nurses' bedrooms and waiting-hall to their former contractor, Mr. D. J. Dolby, 59, Victoria-street, Grimsby. Mr. Dolby has just completed a contract for the electric lighting of the Union of London and Smith's Bank, Limited, Victoria-street, and manager's residence, comprising 130 lights. The installation is in solid-drawn steel conduit, with draw-in boxes, the conductors being drawn after the plastering was completed. The fittings for the manager's residence are of the latest designs in wood by Messrs. Henry Limited, London.

**Glasgow.**—The current supplied by the Corporation in November, 1904, was 18 per cent. above the total of the corresponding month of the previous year. The supply shows an increase of 73 per cent. over the amount supplied in November, 1903. The motors already connected or in process of connection aggregate 7,500 h.p. Most of these are of small size, only about six exceeding 50 h.p. Early this year two three-phase electric generators, driven by steam-turbines of 4,000 h.p. each, will be installed at Port Dundas, and one direct-current plant of 2,000 h.p. in the South Side station. The three-phase generators will supply electric power at high pressure—6,500 volts—and this will be transmitted to sub-stations, where it will be transformed to direct current at 500 volts (as in the case of the tramway supply) for distribution to consumers for power and lighting.

**India.**—*Indian Engineering* notes that sanction has been accorded to an expenditure of over one lakh of rupees for the supply of electricity to the house, etc., occupied by the East Indian Railway Company's servants at the Jamalpur Station. The work will be completed before June next. With regard to the electric installation at the Government Press at Madras, our contemporary states the value of the electric plant introduced in July, 1903, at Rs 80,000. This electrical plant was obtained to improve the method of lighting the whole establishment, and to give power in several departments which the steam-engine could not do. The installation consists of two water-tube boilers, three steam dynamos, nine motors of various sizes for driving the machinery, one constant-current transformer for electrotyping, 523 lamps, and four fans. The incandescent lamps are of 16 c.p., and have been installed throughout the Press.

**Bread without Flour.**—On Wednesday the Shredded Wheat Company, Eastcheap, gave a demonstration at 223, Tottenham Court-road of the process by which they transform grains of wheat into palatable and nutritious biscuits and cakes, which being so easily digestible, might be specially recommended to invalids and children. The process is a particularly clean one, and its interest for us centred upon an electric heater, in which the shredded wheat is cooked during four minutes after it has emerged from the shredding machine. The latter consists of a hopper, into which are placed the grains of wheat, which have previously been cleaned and boiled for half an hour. Thence they fall between two rollers of hardened steel. One of these is smooth, the other grooved; the wheat is pressed into the grooves, and removed from them automatically by a set of needles. The wheat, in the shape of thin threads, falls into a tray, which conveys it to the oven aforementioned.

**Bridlington.**—The Council have adopted a report by Mr. Beckett, borough electrical engineer, on public lighting, showing the average price of 36 towns per lamp and the proposed charge in Bridlington. The average cost per annum of an arc lamp is quoted at £20. 19s. 6d., the proposed charge being given at £15; average cost of Nernst lamp, proposed charge, £5; average cost incandescent 120-watt £7, proposed charge £5; average cost of incandescent 90-watt £4. 15s., proposed charge £4; average charge incandescent 60-watt £3. 10s., proposed charge £3. At those charges Mr. Beckett proposed in the report to introduce 32 arc lamps (660 watts), 15 Nernst (120 watts), 85 incandescent lamps (120 watts), 197 incandescent (90 watts), and 113 incandescent (60 watts), the total cost being estimated at £2,107, and the total candle-power 43,703. The report finally pointed out that the Corporation were at present paying £1,349 for gas lamps with a total candle-power of only 8,384.

**"Maxim" Arc Lamps.**—We are informed that, after severely testing 12 different makes of arc lamps, the Underground Electric Railways Company of London have placed an order with the Sir Hiram Maxim Electrical and Engineering Company for a very large number of "Maxim" DC/Traction Circuit arc lamps. These lamps are intended to burn five in series on 550 volts direct current, and are provided with self-contained line and substitutional resistances and automatic cut-out, and an isolating switch by which one lamp can be trimmed or examined while the other four are burning. The mechanism chamber is completely separate from the resistance, and the over-all length of the lamp is only 28in. A full trim of carbon, 12in. 12 millimetres top and 5in. 12 millimetres bottom, lasts 90 hours with single enclosure globe, and the carbon left in the top holder in just long enough for the bottom holder for retrimming. The isolating switch is operated by means of a key inserted through a watertight self-replacing latch in the case.

**Wrexham.**—The electrical engineer's last report contains the following figures: November, 1904: Used for tramways, 12,444 units; used for lighting, etc., 34,711—total, 47,155. November, 1903: Used for tramways, 14,962; used for lighting, etc., 28,716—total, 43,678. Total number of consumers, November, 1904, 152; November, 1903, 124. During the past few days seven consumers had been connected, and 14 applications were on hand. The distributing cables had been laid from the works along Willow-road, Wrexham Fechan, part of Bennion-road, Salisbury-road, Percy-road, and part of Talbot-road. The trench cutting was rendered more expensive owing to the employment of men out of work. The work of connecting consumers' premises and public lamps was being proceeded with. The minimum charge to consumers on the easy payment system is to be discontinued during the summer months, and current consumed and meter rent only will be debited. The next sections of the mains extension will be (1) along Chester-road to Neville-street, (2) Chapel-street, Poplar-road, and Ruabon-road.

**Bradford.**—The Electricity Committee of the Corporation have now adopted the report of the city electrical engineer (Mr. A. S. Blackman) on the subject of the distribution of electricity. Mr. Blackman recommended (1) that the tramway distribution cables should be augmented as soon as possible upon the present system of supply, with the exception of the Leeds-road and Stanningley and Manchester road routes, for the supply of which sub-stations fed by high-tension three-phase current at 6,000 volts pressure should be employed; (2) that mains extensions outside the area supplied by the existing consumers' network should be carried out upon the three-phase system for both transmission and distribution, and that the introduction of this system should be made at once, commencing with Wakefield-road; (3) that the high-tension current should for the present be generated by means of plant installed in the works for stepping up the low-tension continuous current. The summary of the contemplated expenditure was: for the tramways distribution, including a spare 500-kw. feeder laid into each sub-station, £26,185; for high-tension feeders for general supply to Wakefield-road, Park-avenue, and Otley-road, £4,432; for transforming plant at the works, £10,250—total, £40,867. Since the report was first presented a deputation from the committee has visited Newcastle, Dublin, and Erith to investigate the working of systems similar to that recommended by Mr. Blackman.

**Retford.**—The Mayor of Retford has said, according to the *Lincolnshire Mercury*, there was no doubt in his mind that a system of electric lighting and power was of the first importance for Retford. Referring to arguments used against it at the Traders' Association meeting, he said it was an absurd mis-statement to say that the rich people wanted it for their own special benefit. They could supply their own requirements, as some had already done, without any difficulty, but if Retford was to hold its own and keep abreast of the times, there would have to be an electric installation for the public use. It was more especially useful for small users of power. As a residential town it was also important to them, and he did not think they could afford to lag behind in these days of advancement. They saw small places with from 5,000 to 6,000 inhabitants adopting electrical supply, and in an agricultural town like Stamford it had been a success. It would, he thought, be detrimental to Retford if it remained without a supply of electrical power and light, and he thought the Town Council committed a great blunder when they refused to adopt the very reasonable scheme put before them by Mr. Mountain. It would not have been a burden to the town, but a source of profit, although, of course, it would not begin to pay the first year. He looked upon it as a serious blunder, and it only showed the weakness of municipal government. Although it had grown slowly up to the present, there were possibilities of Retford becoming a large and important town, but it would certainly be retarded by this decision of the Town Council.

**Torquay.**—An enquiry has been held into the application of the Town Council for sanction to borrow £42,000 for a new electric light and power station, to be erected in Upton Valley, near the refuse destructor. Of this total £14,000 will be required for the high chimney and buildings, and £28,000 for the machinery. The new station is an absolute necessity, in consequence of the present station on Beacon Quay being overloaded, and the impossibility of increasing the power there because of the inability to augment the boiler capacity. The increased demand last year over the previous year was 20 per cent., and this year has also shown a 20 per cent. increase over last year, therefore in the event of even a temporary breakdown to one of the sets it would become necessary to shut down the 52 arc lamps in the main streets in order that the spare machinery might supply the current demanded for the shops, hotels, and private houses. With regard to the current for the trams, the Act of Parliament of the Dolter Company provides that the first 100,000 units are to be supplied at 2d. per unit, the next 50,000 at 1½d. per unit, and all above this at 1½d. per unit in any one year. Approximately, the additional cost of the station rendered necessary to supply this current will be about £10,000, being £8,000 for machinery and £2,000 as part of the buildings. It is anticipated that the interest and sinking fund charges upon these two sums will be amply met by the revenue derived from the supply of current to the trams, even after allowing an ample amount for the cost of generation and establishment charges. It is contemplated that, should no unforeseen delay occur, the new station will be practically completed during 1905.

Digitized by Google

**South Africa.**—The demand for electric lighting apparatus throughout Africa is insatiable, says the *African World*. Here are some up-to-date illustrations from the south of the great continent. At Cape Town the Corporation are seeking the sanction of the ratepayers for the completion of the central electric light station, Dock-road, at a cost of £75,000. Even little Greytown, in Natal, has gone in for extensive plant and overhead mains—an indication of what other local authorities all over South Africa will soon be doing—while new dynamos and engines, with double the present capacity, will be required in the New Year. The Port Elizabeth Municipality are calling for tenders in connection with their extensive supply undertaking, including boiler-house plant, engine-room plant, accumulators and boosters, switchboard and instruments, overhead crane, lamps, pillars, motor and electrolytic meters, workshop equipment, etc. All the big towns of South Africa are overhauling and perfecting their telephone systems, and while many orders have already been placed and executed others are in preparation, and will fall to the most enterprising firms. At Johannesburg determined efforts are being made to do away with the causes of dissatisfaction and complaints, and with the New Year many improvements will come into effect, while others are contemplated. In the basement of the telephone tower in Plein-street has been instituted a power plant, constituting two complete duplicate charging outfits, each set consisting of a 60-cycle, single-phase, 100-volt, alternating-current 5-h.p. motor, directly coupled to a generator furnishing 200 amperes at 30 volts. Each motor-generator has sufficient capacity to operate the full ultimate capacity of the storage battery at the normal charging rate. For the purpose of ringing the subscribers' bells there are provided two small motor-generators supplying alternating current at 25 volts, and 1,000 cycles per minute. These machines will later be equipped with the howler, busy-back, intermittent ringing attachments for party-line working, etc. At the side of the generator stands an elaborate power board, while the storage battery is located in the next room. The battery is arranged in two sets, each set consisting of 10 cells of type Tudor storage battery in glass tanks and has a capacity of 580 ampere-hours. The duplicating of the plant ensures continuous service. The British L. M. Ericsson Company were the contractors for the supply of the whole plant.

**Islington.**—At to-night's meeting the Council will consider the following report of the Lighting Committee: "Our attention has been called to the provisions of the London Electric Lighting Areas Act, 1904, by Section 4 of which the Board of Trade are empowered to confirm agreements for the transfer of areas necessitated by the operation of the London Government Act, 1899. The Act affects Islington in conjunction with the County of London and Brush Provincial Electric Lighting Company. The heads of an agreement between the company and the Council were settled during the passage of the Bill through Parliament, as reported to the Council on Oct. 7 last, and we have since been in negotiation with the company as to the amount to be paid by the company and the Council respectively in consideration of the transfer in the one case of such parts of the borough of Finsbury in which the Council are, by their special Act, at present authorised to supply electricity, and in which they have laid electric lighting mains, and in the other case of such portions of the borough of Islington as the company are at present authorised to supply, together with the mains and other works (other than trunk works) in such portions. The borough treasurer has gone carefully into this matter, and for the purpose has made an examination of the company's books. He reports that upon the basis laid down by the agreement referred to the Council have to pay the company in consideration of capital expenditure and three years' purchase of annual revenue a sum of £2,053. 14s. 10d., whilst they will receive from the company a sum of £194. 19s. 9d. only. The difference is explained by the fact that the company had a comparatively extensive system of mains and pipes in those portions of Finsbury which the Borough Council have taken over, while in the portion to be surrendered the Council have invested but little. The Council have already recognised the desirability on the ground of autonomy of giving effect to this transfer, and as the transfer brings with it an estimated additional annual revenue of £382. 12s. 7d. we have no hesitation in recommending that no time be lost in giving effect to it. We have forwarded to the Finance Committee an estimate of £1,858. 15s. 1d., the difference between the amount to be paid by the Council and the company respectively, and subject to its being adopted and submitted by them we recommend: (*a*) That the estimate of £1,858 15s. 1d. submitted by the Finance Committee be approved, and that application be made to the London County Council for their sanction to the borrowing of the amount; (*b*) that the town clerk be authorised to complete the agreement between the County of London and Brush Provincial Electric Lighting Company, Limited, on the basis of the figures above mentioned, and to affix the seal of the Council thereto."

**Electrical Engineering in Scotland.**—An interesting *résumé* of the last year's progress in electrical engineering in Scotland appears in the "Glasgow Herald Shipbuilding and Engineering Annual, 1904." It is divided into two parts—one dealing with the West and the other the East of Scotland. With regard to the former, a Glasgow expert says that electrical engineering has shared during 1904 in the general depression of trade and unsatisfactory scale of prices, the producing power being much in excess of the present demand for plant. The last International Exhibition in Glasgow had led to the discovery by many foreigners and others of the possibilities of electrical business there, and many who came to exhibit had established agencies in Glasgow and energetically entered the field. The local electrical manufacturers had, however, been able to hold their own, and the stress of competition had been met by improvements in design. A given output was now obtained from a considerably smaller and lighter, and, therefore, cheaper machine than formerly. Foreign competition was now almost restricted to electric generating plant of large sizes. He refers to the satisfactory progress made, especially in respect of power supply, in the electricity departments of Glasgow and other Scottish Corporations. He also notes that during 1904 three Clyde shipyards have been completely equipped with electrical plant, and many others have largely extended their electrical machinery, while the field of application of electricity in collieries was also broadening. He concludes by saying electrical engineering generally had been more active during the last three months of 1904 than at any time earlier in the year, and the prospects were all in favour of better business during the ensuing year. On the East of Scotland an Edinburgh expert says that while the closing year had not been signalised by the inception of many such colossal electrical enterprises as were undertaken in 1903, the progress which had been made was of a notably healthy and sound order, indicating that the electrical power movement had gone far beyond the firework display age. He cites specially the progress made with the schemes of the Fife Electric Power Company and the Scottish Central Electric Power Company, and anticipates that with a supply of electric power available at cheap rates a great impetus will be given to trade in the East of Scotland, while owing to the inherent advantages of electric motors, quite apart from the primary point of economy, the condition of the workers as regards cleanliness, comfort, and sanitation will be greatly improved. The British Electric Plant Company, Limited, Alloa, had been able, owing to the largely increasing demand for their products, to give employment to a greater number of hands than in the previous year. Among the principal contracts obtained during the year he cites the following: Some 800 h.p. to 900 h.p. of motors, mostly with self-contained geared shafts, for the Central Marine Engine Works, West Hartlepool; three 250-h.p. generators for Messrs. James Ross and Co., Philpstoun Oilworks; a complete electric power plant, including new electric cranes, etc., for Messrs. Stewarts and Lloyds, Limited, Clydesdale Steelworks, Mossend; extension electric power plant (steam generator and motors), for the Coombs Wood Tube Works of the same firm; several hundred horse-power of motors for Messrs. Peter Spence and Sons, Limited, chemical manufacturers, Manchester; complete electric lighting plant at Mount Melville, St. Andrews; power plant of 650 h.p. and some hundreds of horse-power of motors for the Alloa Coal Company; motor balancers for the Singapore Municipality and for the Northampton Electric Lighting Company; motor-driven plant for the County of Durham Electric Supply Company; shiplighting and power generators for several large liners; and a third repeat order for printing-press equipment from the proprietors of the *Glasgow Herald*.

## PROVISIONAL PATENTS, 1904.

DEC. 19.

**27638. Improvements in vapour electric apparatus.** Charles Proteus Steinmetz, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Dec. 19, 1903, being date of application in United States.) (Complete specification.)

**27640. Improvements in the manufacture of metal caps for to make electrical metallic contact with carbon.** Henry Nehmer, 36, Clifton-street, Finsbury-square, London.

**27683. Improvements in kummeters or instruments for the measurement of wave-lengths in wireless telegraphy.** John Ambrose Fleming, University College, Gower-street, London.

**27702. Method of winding for asynchronous electrical machines for producing a variable number of poles in the propertion of 1 : 2.** (Siemens-Schuckertwerke Ges. mit bes Haft., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 13, 1904, being date of application in Germany.) (Complete specification.)

**27705. Improvements in alternating-current electric motors.** Benjamin Garver Lamme, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 27, 1904, being date of application in United States.) (Complete specification.)

**27707. The manufacture of an indestructible filament for gas and electric lamps for lighting and heating purposes.** Georges Michaud and Eugène Delasson, 4, South-street, Finsbury, London.

**27713. Process for the formation of incandescence bodies for electric incandescence lamps.** William Phillips Thompson, 322, High Holborn, London. (Deutsche Gasglühlicht Akt.-Ges., Germany.) (Complete specification.)

**27714. Electric incandescence lamps with incandescence body fused in the conducting wires.** William Phillips Thompson, 322, High Holborn, London. (Deutsche Gasglühlicht Akt.-Ges., Germany.) (Complete specification.)

**27755. Improvements in counting mechanism more especially intended for use with electricity meters.** Hermann Aron and Oskar Runge, 47, Lincoln's inn-fields, London. (Complete specification.)

**27762. Improvements in electrical apparatus for regulating and distributing electric currents.** Charles Guthrie Conradi, 104, Savernake-road, Hampstead, London.

**27763. Improvements in coin-freed mechanism.** The British Thomson-Houston Company, Limited, and Kenneth Francis Kingwell, 83, Cannon-street, London.

DEC. 20.

**27773. Improvements in and relating to the electro-deposition of metals or alloys on aluminium.** Charles Mason, 6, Finkle-street, Stockton-on-Tees.

Digitized by Google

**27783. Improvements in the method of and means employed for supporting and connecting the trolley wires of overhead electric systems.** Thomas Dawson, Penny Bank-chambers, Halifax.

**27786 Improvements applicable to electric installations.** Frederick Kershaw and William Jasper McSweeney, 4, St. Ann's-square, Manchester.

**27804. Improvements in self-regulating dynamos for train-lighting and analogous purposes.** Charles Dixon Charlesworth, 24, Temple-row, Birmingham.

**27809. Improvements in hydraulic lifts electrically operated** Edmond Meyer Tudor Boddam, Jaffa, Alperton, Middlesex.

**27831. Improvements in incandescent electric lamps.** William Goulton, 114A, Chancery-lane, London.

**27842. Improvements in electric tool drivers.** Philip Arthur Newton, 6 Breams-buildings, Chancery-lane, London. (The American Inventions Company, United States.) (Complete specification.)

**27844. An improved method of controlling electric lifts, elevators, conveyors, or any similar contrivance having a moving car and stations.** Henry Charles Edward Jacoby, 21, Finsbury-pavement, London.

**27859. Improvements in and relating to self-acting cell-switches.** Elektricitäts-Akt.-Ges. Westfalia, 6, Lord-street, Liverpool. (Complete specification.)

**27869. Forming tank for accumulator elements.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27861. Accumulators.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27862. Accumulators.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27869. Improved construction of lock and electrical contact maker and breaker for lifts.** Arthur Charles Burnett and Joseph Richmond, 173, Fleet-street, London.

**27887. Improvements in vapour electric apparatus.** Ezechiel Weintraub, 83, Cannon-street, London. (Date applied for under Patents Act. 1901, Dec. 21, 1903, being date of application in United States.) (Complete specification.)

**27900. Secondary batteries.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27901. Storage cells.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27902. Secondary batteries.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27903. Secondary batteries and grids therefor.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27904. Secondary batteries.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27905. Grid or element for secondary batteries.** William Gardiner, 65, Chancery-lane, London. (Complete specification.)

**27906. Improvements relating to magneto-electric ignition devices for explosion engines.** Gustav Michalek, 7, Southampton-buildings, Chancery-lane, London.

**27913. Improvements in telegraphy.** Robert James Sheehy, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**27916. Improvements in locking apparatus for watchmen's electric controls and the like.** Horst Hindersin, 8, Buckingham-street, Strand, London. (Complete specification.)

**28166. System of connections for the generation of electric oscillations.** Gustav Eichhorn, 216, Friedrichstrasse, Berlin, Germany. (Date applied for under Patents Act, 1901, Dec. 20, 1903, being date of application in Germany.) (Complete specification.)

DEC. 21.

**27926. Improvements in or connected with electric demand or rebate indicators.** Frank Michael Lewis and the Reason Manufacturing Company, Limited, Norfolk House, Norfolk-street, Strand, London.

**27929. Improvements in electrically-operated block signalling apparatus.** Charles William Skinner Turner, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Dec. 22, 1903, being date of application in United States.) (Complete specification.)

**27950. Improvements in fused electric motor switches.** Francis John Everson Clarke and George Arthur Pope, 138, Birchfield-road, Handsworth, Birmingham.

**27963. Improvements in or relating to storage and other batteries.** The N. S. Electric Storage Company, Limited, and Job Thomas Niblett, 139, Queen Victoria-street, London.

**28018. Improvements in safety discharge apparatus for excessive voltages in electric circuits.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke G. m. b. H., Germany.) (Complete specification.)

**28044. Improvements in electricity meters.** Stanley Matthews, 4, South-street, Finsbury, London.

**28036. Means for automatically connecting up with each other the subscribers to telephone exchanges.** Josef Peticky, Ivan Cizek, and Frantisek Suchanek, 72, Cannon-street, London. (Complete specification).

**28062. Improvements in treated carbon and in methods of producing same.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**28063. Improvements in scouring machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

DEC. 22.

**28113. Improvements in electrical heating apparatus, especially applicable to flatirons and the like.** William Eastman and Alan Warne, 40, Chancery-lane, London.

**28114. Improvements in automatic controlling apparatus for operating electric switches or cut-outs.** Charles Mark Dorman, Reginald Arthur Smith, and Herbert George Bagge, Ordsal Electrical Works, Salford.

**28122. Improvements in and relating to electric ignition devices for internal-combustion engines.** James Paxman and Davey, Paxman, and Co., Limited, 70, Chancery-lane, London.

**28123. Improvements in and connected with counting apparatus for electric current, gas, water, or similar meters.** Fritz Biermann, 37, Chancery-lane, London. (Complete specification.)

**28129. Improvements relating to permeable diaphragms for use in electrolytic cells, filtering apparatus, and like purposes.** Heinrich Hertz, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**28147. Improvements in or relating to electric vapour apparatus, especially electric lamps of the character known as electric vapour lamps, or vapour arc lamps in part applicable to other electric vapour apparatus.** Charles Orme Bastian, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**28154. Improvements relating to the manufacture of light-emitting bodies for electric incandescent lamps.** Hans Kuzel, 322, High Holborn, London.

**28155. Improvements in dynamo-electric machines.** The Phœnix Dynamo Manufacturing Company, Limited, Robert Pohl, and Felix Pohl, 322, High Holborn, London. (Complete specification.)

**28156. Improvements relating to the construction and ventilation of field coils of dynamo-electric machinery.** The Phœnix Dynamo Manufacturing Company, Limited, and Robert Pohl, 322, High Holborn, London. (Complete specification.)

**28157. Improvements in and relating to actuating apparatus for magneto-electric spark ignition apparatus and the like.** Gustav Adolf Unterberg, 322, High Holborn, London. (Complete specification.)

**28163. Improvements in telephone systems.** John Young, 21, Gloucester-walk, Campden-hill, Kensington, London.

DEC. 23.

**28175. Improvements in and relating to electric tramways and railways.** Frederick Walter Baynes, 51, Elmside, Exeter.

**28176. Improvements in the method of and means employed for regulating electrical energy in an alternating-current circuit.** Harold Emmott, Penny Bank-chambers, Halifax.

**28179. Improvements in telephone indicators.** William Aitken, care of British Insulated and Helsby Cables, Limited, Edge-lane, Liverpool.

**28208. Improved trolley head.** James Burns and James Douglas Allan, 65, Chancery-lane, London.

**28211. An improved electric lamp for use by divers and others under water.** John Briggs Stewart, 100, Wellington-street, Glasgow.

**28212. Improvements in connection with trolley poles for overhead electric traction.** Frederick George Squirrell, 55, Chancery-lane, London.

**28235. Improvements in electric arc lamps.** John William Ewart, 36, Chancery-lane, London.

**28238. Improvements in alternating-current motors.** Bruce Peebles and Co., Limited, and Jens Lassen La Cour, 34, Castle-street, Liverpool.

**28252. Improvements in or relating to electrical switches, plugs, and the like.** William Winstanley Strode and George Hendry White, 111, Hatton-garden, London.

**28253. Improvements in or relating to incandescent lamp holders.** William Winstanley Strode, 111, Hatton-garden, London.

**28254 Improvements in electric telegraphs.** Foster Ritchie, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**28255. Improvements in electrical relays.** Foster Ritchie, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**27268. Improvements in and relating to telegraph transmitting instruments.** Frederick Herbert William Higgins, 18, Southampton-buildings, Chancery-lane, London.

Digitized by Google

**23270. Improvements in or relating to safety devices and appliances for use in connection with suspended electric conductors.** Alfred Charles Bray and William Aitken, 30, Moorgate-street, London.

**23278. Improvements in instruments for indicating the charged or uncharged condition of electric cables or other electric appliances.** William Mundell Thornton, 18, Buckingham-street, Strand, London.

**23279. Improvements in electric arc lamps.** William James Davy, 40, Chancery-lane, London.

**23301. Improvements relating to electric welding.** Sebastian Ziani de Ferranti, 18, Southampton-buildings, Chancery-lane, London.

## COMPLETE SPECIFICATIONS ACCEPTED

*To be published Jan. 12, 1905.*

1904.

**2495. Electric gas or vapour lamps or like apparatus.** von Recklinghausen.

**2707. Electrostatic wattmeters.** Wilson.

**3010. Electric traction on a road contact or like system.** Ross and Matthews.

**3305. Electrical measuring instruments and apparatus for use therewith.** Fisher.

**3340. Controlling apparatus for electric motors.** Klinkenberg.

**3384. Alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**3391. Electrical energy meters.** Lake. (Arno.)

**3396. Method of and means for protecting apparatus on alternating-current systems.** Merz and Price.

**3935. Electric cable troughs or conduits.** Seacombe Pressed Brick and Tile Works, Limited, Wilson, and Jones.

**3995. Electric couplers.** British Thomson-Houston Company, Limited, and Cubitt.

**4059. Electric furnaces.** Simm, Simm, Storey, and Sellers.

**4134. Arc lamp electrodes.** Levis. (General Electric Company.)

**4336 Means or apparatus for controlling incandescence electric lamps.** Ferguson.

**15343. Electric railways and tramways on the overhead conductor system.** Anderson and Dunne.

**17532. Electric filters.** Hinkson and Hey.

**19366. Galvanic cell.** Ziegenberg.

**19997. Apparatus for regulating the voltage of electrical circuits** Stuart. (Date applied for under International Convention, Sept 26, 1903.)

**22355. Telephone installations.** Deutsche Telephonwerke R. Stock und Co., G. m. b. H. (Date applied for under International Convention, Aug 25, 1904.)

**22695. Thermo-electric generators.** Howorth. (Haskell.)

**22880. Process for smelting nickel ores in an electric furnace, and crucible therefor.** Société Electro-Metallurgique Française. (Date applied for under International Convention, Oct. 30, 1903.)

**23769. Telephone system.** Barnes.

**23907. Trolley restorers.** Calahan. (Date applied for under International Convention, Nov. 6, 1903.)

**23932. Trolley wire supports.** Paton.

**24360. Arrangement of electric emergency lamps in theatres and like buildings.** Brandt.

**24951. Medical electric and magnetic appliance.** Cooke and Cooke.

**25078. Electric ignition devices for internal-combustion engines.** Aron. (Boulez.)

**25106. Apparatus for regulating the current through an electric lighting circuit.** Prested.

**25114 Electric accumulators.** De la Croix and Joel.

**25128. Fireproof, acid-proof, and electrically insulating material.**

**25129 Electric braking apparatus.** Thompson. (Stamm and Lewis.)

**25218. Enclosed electromagnet.** Perrett. (Date applied for under International Convention, March 12, 1904.)

## NOTES.

**Liege Exhibition.**—An interesting feature has been decided upon by the organising committee of the Liège Exhibition (electrical section), which will be at once useful and novel. In addition to the large firms and inventors, a considerable space will be specially reserved for working electricians. No employer of more than five men will be admitted, and the employer himself must be a working electrician. Small employers will pay a small charge for space, which will be free to workmen exhibitors. The purpose of this reservation is to throw open a field for apparatus and inventions which would otherwise seldom come before the public.

**Bournemouth.**—The recent arbitration between the Corporation and the Poole and District Electric Traction Company illustrated how experts may differ. The company claimed £427,619, and one of their witnesses, Mr. More, estimated the value of the undertaking at nearly £460,000. The most modest estimate on their behalf figured at £377,732. For the Corporation, who offered £55,000, the appraisements ranged from Mr. F. W. Lacey's £55,379 to Mr. Waller's £70,400. The Corporation are very well satisfied with the award, which fixes the purchase price at £112,000, in addition to which a sum of about £6,000 is to be paid for items previously agreed upon. We hope to see the different lines linked up at an early date, and welded into a harmonious and successful system.

**Free Lamps.**—The need of seeing that lamps of good quality are used by light consumers has been recognised by the Twickenham and Teddington Electric Supply Company, Limited, who have decided to renew lamps gratuitously. The consumers will, in fact, be allowed to exchange them as frequently as they wish. This judicious step will doubtless do much towards removing complaints as to indifferent light, which are commonly traceable to the practice of many consumers in buying cheap and inferior lamps. It is gratifying to see that electric light undertakers are evincing a spirit of enterprise with a view to relieving electric illumination from the handicap under which it has laboured. The greater satisfaction of the consumers, and the resultant increase in their numbers, may be depended upon to defray, and, in the course of time, to more than recoup, the outlay under this head.

**Nobel Peace Prize.**—The Board of Education has received through the Foreign Office an intimation that, in order to be eligible for the Nobel Peace Prize, which will be awarded in December, 1905, candidates must be proposed to the Nobel Committee of the Norwegian Parliament before Feb. 1. The following persons only are qualified to recommend candidates: members of the Nobel Committee of the Norwegian Parliament; members of the Legislatures and Governments of different countries, and of the Commission du Bureau international permanent de la Paix; members and associates of the Institut de Droit international; professors of law and political science, of history, and of philosophy in the universities; and winners of the Nobel Peace Prize. The Nobel Peace Prize can be granted to an institution or an association, not only to an individual. Enquiries for further information should be addressed to the Comité Nobel du Parlement Norvégien, Victoria-terrasse 4, Christiania, Norway.

**St. Louis Exhibition.**—The closing ceremony in connection with the great fair is thus picturesquely described by the *Western Electrician* of Chicago: "Promptly at 12 o'clock midnight President Francis, surrounded by a crowd estimated at 100,000 persons, threw a switch which had been arranged at the foot of the Louisiana Purchase Monument, and slowly, as though reluctant to lose its beauty, the grand illumination dimmed. Simultaneously, the current which operated the cascades was cut off, and with the darkening of the main picture the beautiful torrents of foaming water were for ever silenced." It will be seen that the electrical department, which has been so conspicuous throughout the exhibition, died hard. The final statement of the officials in regard to the attendance throughout the 187 days places the total at 19,694,855, of whom, however, only 12,804,616 paid for admission, which, it may be remarked, is less than half the number for the Chicago Exhibition. The concluding day was naturally crowded, 203,101 sightseers being present.

**Wireless Telegraphy.**—An agreement has been concluded between the Italian Government and the Marconi Company for the construction of a powerful station at Coltano, intended to communicate with stations in Great Britain, Erythrea, the Netherlands, and other countries. In connection with the agreement entered into between the company and the British Government for the transmission of messages to ships at sea, the Postmaster-General has authorised the use of abbreviated or registered telegraphic addresses of firms or individuals in sending wireless messages to or from the vessels, subject to the same regulations as those governing inland telegrams. It is reported that arrangements are being made to fit up the trains of the New York Central and the Lake Shore Railroads with wireless telegraphy apparatus to enable passengers to send and receive messages at any time. Satisfactory experiments are stated to have been made of a combination of the present signalling system and wireless telegraphy by which engine-drivers can be warned of any danger.

**Reduced Cost of Electricity.**—A lady writing in a New York journal bewails the increased cost of living in the States, particularly in that city. Her contention is amply exemplified in two columns of figures, which demonstrate the advance in prices that has occurred during the past decade, especially in the necessaries of life. Besides this, our esteemed contemporary the *Electrical World* weighs in with an important exception to prove the rule—electricity. There is not a department of electrical service to the public that is not cheaper and better in 1904 than in 1894. Trolley rides for five cents are much longer, the universal transfer system has cut the fare to much below five cents, and the service is infinitely improved, on surface, overhead, or underground. Telephony is better, quicker, much cheaper, and available to everybody. Electric light and power are both cheaper and better, all over the country as in New York, and while the cost of every constituent item entering into production has risen—fuel, wages, rent, taxes, etc.—the price of current has been persistently lowered.

**Poor Potsdam!**—The Kaiser is exceedingly jealous about anything concerning Potsdam, for it was there that his "never-to-be-forgotten" ancestor the great Frederick was born. Lately it has become recognised as imperative that electric traction shall supersede the old horse trams, but in the middle of the road connecting the town with the railway station are the remains of the old linden tree around which the people were wont to attend upon Frederick with petitions. This would have to be removed, and though it is but a remnant of decayed timber, encased in zinc and propped up by iron supports, the Kaiser insists that sentiment shall prevail over utility. His Majesty, however, is not actuated by historic considerations alone. In the character of æsthete he also objects to the use of the overhead system on this road, and suggests that the best plan would be to use an alternative route, which should also be

Digitized by Google

well away from the palace. It is estimated that an additional expenditure of over £60,000 would be entailed, but "the Kaiser has promised that the State shall bear half." As the Potsdam coffers are not overloaded, even a moiety of this sum represents a substantial tax, and a number of the inhabitants consider hero-worship rather dear at the price; but it looks as though the town will have to acquiesce—or, at any rate, to pay.

**The L.B. and S.C. Experiment.**—It is now definitely announced that the section between Peckham Rye and Battersea Park is to be converted to electric traction by way of experiment. This section, which is five miles in extent, is in the centre of the company's heaviest suburban traffic. For some two years the details of the scheme have engaged the attention of the company's consulting electrical engineer, Mr. Philip Dawson, who, with his marked predilection for the overhead system, has convinced the directors of its advantage. When the electrification of this section has been completed, it is intended at first to run a few trains during the late morning and early afternoon on the "shuttle service," passengers for a longer distance than the one electrically traversed having to change at each end. By this arrangement the quick transit of the early workers will not be interfered with. The general manager and consulting engineer have great confidence in the success of the experiment, which they expect to result in the prompt electrification of the lines to London Bridge and the West-end. It will be remembered that when Mr. Dawson gave evidence before the London Traffic Commission he advocated electric traction in the most unmistakable manner. The company is building a power station at New Cross for lighting purposes, but an outside supply will probably be obtained for running the experimental trains.

**The Clock of the Future.**—Mr. Henry Cunynghame has just completed his interesting course of Christmas lectures at the Royal Institution on "Ancient and Modern Methods of Measuring Time." At the conclusion of Thursday's lecture he showed an electric clock which had been connected with wires to two dials in the gallery of the theatre, and said that no doubt the electric clock, when one clock in a house gave the time to any number of dials, was the clock of the future. He showed how, by the aid of a few dry cells, clocks are made to wind themselves automatically, never requiring to be wound by hand, and how one single master clock of this kind could be arranged to send a current every minute or half-minute to any number of dials in the same house or town, so that their hands would move on step by step with those of the master clock, and would always show the same time as it did without any attention for winding. In the course of the concluding lecture Mr. Cunynghame showed various apparatus by means of which minute divisions of time are measured, including an electrically operated tuning-fork. Mr. Esmond Morse, who had rigged up some of these instruments, assisted in their demonstration. The course concluded with a demonstration of the well-known mirror arrangement for the testing of the speed of light, and an earnest appeal by the lecturer to parents to allow their children as much as possible the use of instruments in order to assist them in their studies of physical phenomena.

**The Northumberland Clause.** — Hitherto St. Stephen's has been the venue for contests over the Bermondsey or Northumberland clauses, but the Torquay Gas Company initiated a departure the other day by appearing before the Local Government Board inspector, and preferring a request that sanction to the Corporation's application for a loan of £42,000 for new electricity works should be conditional upon the observation of the Northumberland clause. This procedure, if not *ultra vires*, is of a novel character, and we notice that it elicited scant encouragement from the inspector, who stated that he was in attendance to enquire into the merits of the scheme, and not into any conditions. The *Gas Journal* seeks consolation in the circumstance that "it is not an unknown thing in recent times for the Local Government Board to look a little more closely than of old into applications from the point of view of how the ratepayers are likely to fare in respect of the scheme for which the money is required." Allowing our contemporary's statement that the undertaking has only just made both ends meet, and that the present station is unable to meet any increased demand, the enlarged works will more than enable the Corporation to supply the Dolter Traction Company, leaving a margin for new light consumers. The gas company, by the way, are indefatigable rivals. It will be remembered that they were very busy last year with their opposition to the tramway scheme. They claimed special protection against electrolysis, and their activity has evidently not abated.

**Hiring of Motors.**—In the same way that electric light undertakers have found it advisable to adopt some system of free wiring to increase the number of consumers and the hiring out of motors and other accessories for the development of their power department, so the large power companies are experiencing the need of a somewhat similar method in their case. We have recently been informed that the Lancashire Electric Power Company have inaugurated a special branch with the object of hiring out apparatus to new consumers on the hire-purchase system, so as to develop their business in the large area over which they have the right to supply power. A would-be consumer of power is faced with a heavy charge for installing electric motors, and, at the same time, he frequently has still to bear the standing charges on the engine and boilers which have previously furnished him with the power required in his factory. Consequently, the initial expense attendant upon the purchase of motors is often the deterrent which militates against a change of driving system to the electric on the part of manufacturers. The hire-purchase system now being organised in Lancashire will, however, largely dispose of this obstacle. The saving in annual cost from the use of electric power will soon wipe out the hire charge, and the payment for the apparatus being spread over a number of years becomes less onerous. We understand that this system is already having a good effect in bringing in business, and that Mr. Philip C. Pope has been appointed engineer-in-charge of the department.

**The Telephone Situation.**—The rumour freely circulated in the daily Press at the end of last week to the effect that the Government had acquired the undertaking of the National Telephone Company, was promptly contradicted by an official communication from the Postmaster-General. It will be remembered that Lord Stanley gave an assurance last session that he would not conclude any such agreement before Parliament had had an opportunity of considering the terms. The following passage in the official disclaimer suggests, however, that a pronouncement from his lordship is to be expected on the reassembling of Parliament: "The negotiations between the Government and the company are not yet concluded, and in any case no announcement on the subject will be made till Parliament meets." The rumour speedily reflected itself on 'Change, though a financial contemporary suggests it was just as likely that the reverse was the case, and that a rather unusual amount of buying early on Friday last may have prompted the rumour. Whatever the cause, the deferred stock gained 11 points in a day, receding five points on Lord Stanley's announcement, which, by the way, does not preclude the possibility of a conditional understanding having

Digitized by Google

been arrived at. A suggestion has gained currency that the company may be transformed into an authorised Government agency, the country becoming proprietors of the company's undertaking—and of its liabilities—while the company would conduct the service in return for a share in the net profits. In any case, it is to be hoped that Lord Stanley will make a definite announcement in regard to the Government's policy early in the new session.

**North-Eastern Railway Company.**—For some weeks past there has been friction between the company and the holders of first-class season tickets on the electrified section. This culminated in a meeting of the aggrieved passengers at Newcastle on Monday, when the services of a duke — his Grace of Northumberland — were enlisted as president. In the end the ticket-holders resolved, like the telephone users of Paris, to constitute themselves into a protection association. The company have sought to amalgamate the classes on the electric trains, and have inserted a clause in the first-class contract tickets that passengers may travel first class only when accommodation is provided. At present the accommodation is alleged to be inadequate, overcrowding general, and the number of conductors insufficient. One of the speakers said that first-class season-ticket holders were compelled to travel with drunken men, who used objectionable language and spat on the floors. The Duke of Northumberland, referring to a notice just issued by the company that the limited supply of first-class carriages did not apply to main lines, became scathing in his criticism. The company, he said, knew better than to act in such a manner where main lines were concerned, because they came into competition with other railways. A series of resolutions embodying the complaints was duly carried. One can sympathise with the company in their desire to have a uniform class of compartment, but the demand for first-class accommodation on this line appears to be decidedly strong. A little while back, if we recollect aright, the company made a provisional promise to the first-class season-ticket holders. Would it not be as well if a definite statement of policy were now made?

**Faraday House.**—The January issue of the *Journal*, which will probably be the last number in its present form, opens with some entertaining paragraphs, and Faradians contribute articles upon "The Artificial Lighting of Picture Galleries," "The Electrical Engineers, R.E.V." (illustrated), and "The Best System of Alternating-Current Traction for Long-Distance Lines" (illustrated). There is a portrait and biographical notice of Mr. Robert Hammond, an account of the litigation over the "ancient lights" question (from which the society emerged successfully two or three weeks ago), and some miscellaneous features. In his notes on the lighting of picture galleries, Mr. W. T. Wheeler says that, although the acetylene gas light is hard to beat, preference must be given to the incandescent electric light on account of its all-round convenience. He considers it desirable to over-run the lamps, or to use high-efficiency lamps, owing to the better quality of the light obtained for this special purpose. For large pictures Mr. Wheeler advocates Nernst lamps, and in his conclusions he emphasises the point that in a picture gallery the light should illuminate the pictures, not the spectators. The article on the Electrical Engineers traces the progress of the corps from its first commanding officer, the late Dr. John Hopkinson, up to the present time, and there are several excellent photographs. In his paper on "The Best System of Alternating-Current Traction for Long-Distance Lines," which was awarded the prize for third-year students, Mr. H. W. Swann sums up favourably to the Winter-Eichberg repulsion series motor, pointing out, however, that it would be premature to deliver a definite pronouncement. It will be seen that the final issue of the present publication lacks nothing in interest.

**More Rapid Telegraphy.**—The high-speed telegraph system just devised by Messrs. Siemens and Halske requires only one wire for the transmission and reception of messages. Another advantage is that the receiving apparatus prints the message in plain printed characters. In the first place the messages are written on a typewriter, which, instead of printing letters, perforates holes in a paper ribbon. This ribbon is then inserted into a transmitter which reproduces the perforated dispatch at its destination. A disc with trans parent letters revolves in front of the ribbon perforated at the receiving station, and by means of a small electric lamp each letter, on which the electric light shines through the perforations, is photographed on a ribbon of sensitive paper. A special paper has been invented for photographing the messages. This goes on at the rate of about 2,000 letters per minute. It will be seen that the system is almost a photographic equivalent of the tape machine so familiar in clubhouses. In case of a lengthy dispatch several typewriters are employed in perforating the messages. It is proposed to set up perforation writers with ordinary typewriter keyboards in various offices, so that messages can be handed in ready for transmission. In dispatching messages through various stations, it is only necessary to use the perforated ribbon received on the fresh transmitter, a great saving of time being thus effected. It is reported that the system has been tried with success over the Government wire between Konigsberg and Berlin—a distance of over 500 miles. The inventors of the Pollok-Virag system desired to exploit their apparatus here because there was not sufficient work for it to do in their own country, and it seems as though the Siemens and Halske method also will only be used to its full capacity between large commercial centres.

**Iron and Steel Institute.**—The following circular has been issued by the council with regard to the Andrew Carnegie research scholarship: "A research scholarship or scholarships, of such value as may appear expedient to the council of the Iron and Steel Institute from time to time founded by Mr. Andrew Carnegie (president), who has presented to the Iron and Steel Institute 64 1,000dol. Pittsburg, Bessemer, and Lake Erie Railroad Company 5 per cent. debenture bonds for the purpose, will be awarded annually, irrespective of sex or nationality, on the recommendation of the council of the institute. Candidates, who must be under 35 years of age, must apply on a special form before the end of February to the secretary of the institute. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students who have passed through a college curriculum or have been trained in industrial establishments to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. There is no restriction as to the place of research which may be selected, whether university, technical school, or works, provided it be properly equipped for the prosecution of metallurgical investigations. The appointment to a scholarship shall be for one year, but the council may at their discretion renew the scholarship for a further period instead of proceeding to a new election. The results of the research shall be communicated to the Iron and Steel Institute in the form of a paper to be submitted to the annual general meeting of members, and if the council consider the paper to be of sufficient merit, the Andrew Carnegie gold medal shall be awarded to its author. Should the paper in any year not be of sufficient merit, the medal will not be awarded in that year."

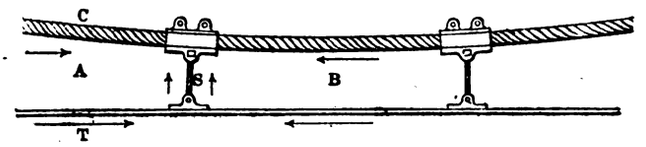
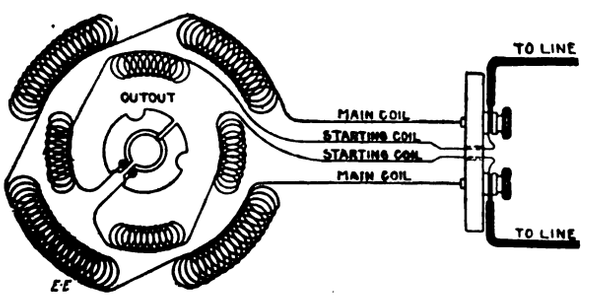
**An Alternating-Current Rectifying Effect.**—A recent issue of the *Electrical World* contains a letter from Mr. I. D. Paton containing the remarkable proposition that a direct current flows between a copper trolley wire and its steel suspension cable when both are employed in parallel with alternating-current railway motors. In Section A of the accompanying diagram the current is flowing from left to right. Mr. Paton states that by virtue of the inductance of C there will be a lag in the rise of E.M.F. to a maximum relative to that in T for equal distances between the point of application and the withdrawal of energy, so that there will be a balancing current from T through S. The balance will occur when the E.M.F. crosses the zero line.



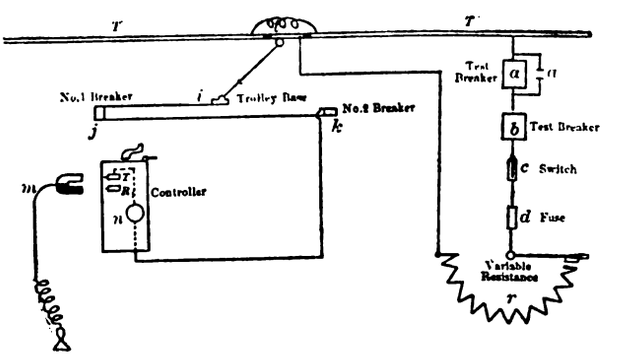
Similarly, in case B, where the current is flowing in the reverse direction, the same action takes place, and a balancing current will again flow from the copper trolley up the suspenders to the cable. As both the steel suspension cable and the copper trolley wire carry alternating currents in parallel, it is not obvious why a rectified current should flow through any of the suspension ears. Although the different resistance and greater inductance of the steel cable, as compared with the copper trolley wire, would cause a delay in phase with respect to the current in the trolley wire, this difference in phase does not seem to involve any interchange of current, and if interchange of current took place, it would be an alternating current. The difference in the metals presents a number of secondary possibilities, such as thermo-electric action, but we echo the suggestion of our contemporary that their correspondent should make some measurements of the alleged rectified currents so as to elucidate this interesting phenomenon.

**Single-Phase Induction Motor.**—A new type of small automatic starting induction motor has been put on the market by the Emerson Electric Manufacturing Company, of St. Louis, a description of which appears in the *Western Electrician* of Chicago. The sizes range from $\frac{1}{10}$ h.p. to $\frac{1}{60}$ h.p., on 60-cycle current, with speeds of from 1,150 to 1,800 revolutions per minute. A feature of them is the limited



space required. While they have less radiating surface than those hitherto made by this company, they are guaranteed to carry full rated loads without injurious heating. They operate at a constant speed, which cannot be changed. Speed is dependent upon the number of field poles in the winding and the frequency of the current—*e.g.*, a four-pole motor will operate on 7,200 alternations (60 cycles) at a speed closely approaching 1,800 revolutions per minute. The motors are not designed to start under any great proportion of full rated load. They are constructed with a patented divided-pole form of field winding, comprising an equal number of main and auxiliary or phase coils. The latter, which are used for starting, are entirely independent of the main field coils, and are in circuit with the line only when the motor is starting. As shown in the illustration, they are controlled by an internal automatic switch, which disconnects them after the motor has attained sufficient speed. The armature is of the squirrel-cage type, and has no insulated winding at all. In the binding post arrangement the main field coils are connected in series, and the leads are attached to the binding posts inside the motor. The starting coils are connected in series with the automatic cut-out, and these leads are brought out through the binding-post block and connected to the binding posts outside. The motor may be readily reversed by changing these leads to opposite binding posts. These motors operate satisfactorily on current exceeding their rating by not more than 10 per cent.

**Testing Car Circuit Breakers.**—A simple method of rapidly testing a car circuit-breaker adjustment is the subject of an article in the *Street Railway Review* by Mr. E. C. Parham. Assume that the house service trolley wire, denoted as T' T' in the accompanying diagram, has a short length insulated from it by line breakers on both ends Circuit breakers, *a*, *b*, in series with each other, are likewise in series with switch, *c*, fuse, *d*, and variable resistance *r*, which may be a water rheostat. Breaker *a* has a pair of contacts which close the circuit after it has been momentarily opened, the object being to obviate the loss of time consequent upon reclosing the breaker by hand.



When all breakers, switches, and fuses through the test path are closed, the short insulated section is alive, so that if the trolley wheel of a car bears up against this section, and one of its controllers is advanced to an operating notch the car will take current through its normal working circuit and tend to start. To obviate this the author employs the forked device, *m*, of which the unshaded tongue is made of flat copper, and the shaded tongue of hard flat insulation, and which terminates on a flexible lead grounded to a track rail, with the result that the current cannot reach the motor circuit as long as the controller is not advanced beyond the first notch. Taking the standard adjustment of the car breakers for the purpose of calibrating the test circuit as 200 amperes, breaker *a* is adjusted, by means of an ammeter and the variable resistance, *r*, to operate at about 190 amperes, and breaker *b* about 210 amperes, the margin being corrected later after experience. A car is located so that its trolley wheel rests on the insulated section, and the controller nearest the car breaker to be tested is advanced to the first notch, and the forked contact, *m*, placed under controller fingers, T and $R_1$. The test breakers are then closed and the rheostat operated to gradually increase the current until one of the breakers acts. If breaker *a* operates first, it is an indication that 190 amperes are insufficient. If the car breaker under test operates next, it becomes certain that its adjustment lies between 190 and 210 amperes, which would be considered a good condition. If breaker *b* acts before the car breaker, the adjustment of the latter needs a greater current than 210 amperes, entailing a slacking off of the breaker adjusting screw. Operation of

Digitized by Google

the car breaker before breaker *a* would show the former to be adjusted for too low a current, impeding the operation of the car. It will be seen that, in general, a breaker which operates between *a* and *b* is safe.

**The American Institute.**—We have received a copy of this society's *Transactions* for December, which contains papers on "Heavy Electric Traction" and "The Maximum Distance to which Power can be Economically Transmitted," by Messrs. O. S. Lyford, jun., and Ralph D. Mershon respectively. In the latter paper the author rests his calculations upon the present condition of electrical science, which he acknowledges may prove a doubtful basis. He hints at the possibility of devising some better mode of transmission, "not involving the use of lines," and considers it not improbable that skill and experience will eventually so modify methods of construction as to greatly affect his present conclusions. Besides this, industrial and financial conditions may undergo a change favourable to electrical engineering. In his present calculations the maximum amount of power dealt with is 500,000 kw., which he states is probably too high to be seriously considered to-day, but he gives 200,000 kw. to 300,000 kw. as within the range of immediate future possibility. On these figures he gives the maximum distance for the present outlook as about 550 miles. The limit, he finds, is fixed, not by physical, but by economic, conditions. Thus, "all the elements in the annual cost per kilowatt for transmitting power, except those dependent upon the line conductors, may be continually reduced by increasing the amount of power to be transmitted. The annual cost per kilowatt due to the line conductors cannot be so reduced. It can be determined only by such other means as will reduce the first cost of the conductors. As the first cost of the line conductors can be reduced only by increasing the voltage of transmission, and as there is a limit to which increase can be carried, it follows that *the limiting distance to which power can be economically transmitted will depend, finally, upon the cost of the line conductors and upon this alone.*" The author found to his surprise that the limit of voltage is also governed, not by atmospheric losses, but by economic conditions; but he predicts that when the demand comes for units of the large capacities contemplated, voltages greatly in excess of those now used will be practicable, larger transformers facilitating construction for this purpose. The issue also contains the discussion on "The Telautograph" and "The Transposition of Electrical Conductors."

**Institution of Civil Engineers.**—A large audience assembled in Great George-street to hear Sir William White's account of the American tour undertaken by the institution last year during his term of office. Sir William White prepared his paper at the express wish of the president and council, who desired that the *Proceedings* should contain a record of a visit paid to America for the first time in the history of the institution by a representative body of its members. The party mustered in New York to the number of 72, exclusive of many ladies, and had to face a hard month's work in order to fulfil numerous engagements at places far distant from each other, and to inspect many important works The first reception of the party by the American Society took place on Sept. 13. A notable feature of the gathering was the presence of Mr. Charles Haswell, the "father" of living engineers, who is in his ninety-seventh year. He was the first engineer-in-chief to the United States navy, more than 60 years ago. Sir William referred to the engineering achievements of Greater New York, embracing bridges, tunnels, trains, trams, deep-water approaches to the harbour, berths and warehouses for shipping, great steam ferries plying across the noble rivers, telegraphs and telephones, "sky-scrapers," water supply, and great sewage systems. The new rapid-transit subway was duly inspected. Sir William remarked that the opportunity of inspecting a number of the largest high buildings was the more valuable in view of the growing adoption of steel structures for building purposes in this country, and it was satisfactory to note that in the production of special sections of steel joists and girders suitable for such buildings the most recently designed British steelworks compared favourably with those of the United States. In both countries built-up sections were giving place to rolled sections, and in both countries H-shaped joists up to 2ft. in depth were now obtainable in the greatest lengths required for buildings. He found the spectacle presented by the sky-scrapers from the harbour of New York remarkable and interesting, but, in spite of their advantages in concentrating business, he was personally not desirous of seeing a similar group of buildings in any city of Great Britain. In Chicago, the birthplace of the sky-scraper, a law had been passed limiting the height of new buildings to 150ft., and that example would probably be followed elsewhere. On Sept. 19 the party left New York by special train for Montreal, whence they went to Quebec, Ottawa, Toronto, and Niagara. No engineer visiting Canada, said Sir William, could fail to be impressed by the enterprise and courage with which the Government and private associations were facing great schemes for the development of the Dominion's resources—the construction of a new transcontinental railway, the fuller utilisation of numerous sources of water power for electrical purposes, and the improvement of the waterways between the great lakes and the Atlantic. The party were enabled to see some examples of the most characteristic features in these developments. At Quebec they saw the works in progress for the new railway bridge, to be constructed on the cantilever principle, with a channel span of 1,800ft. (100ft more than the Forth Bridge), containing a suspended span of 675ft. and two cantilever spans each of 562½ft. They visited the Soulanges Canal, the electrical equipment of which was described in our last week's issue. Many opportunities were afforded to see examples of the utilisation of water power, and no one could fail to realise the enormous possibilities of development in the pulp and paper industry, with cheap power and a good supply of labour. At Niagara, on the Canadian side, three new undertakings were being rapidly advanced, together giving over 400,000 h.p., while a fourth would yield 40,000 h.p. When these were completed the grand total of power derived from Niagara on both sides of the river would be about 700,000 h.p. Sir William paused to lament that two of the three big undertakings on the Canadian side were practically due to American capital and enterprise. Subsequently the party arrived at St. Louis, and attended the International Engineering Congress. In conclusion, Sir William remarked that this visit would undoubtedly be of benefit to British engineering, since it included exceptional opportunities for obtaining particulars of the latest American and Canadian practice. Beyond that, however, the friendly intercourse would tend to strengthen the amiable feeling already existing between the United States and the British Empire, and must result in a better understanding between the mother country and Canada, whose loyalty to the British Empire was undoubted, and had been established by noble deeds. The development of the Dominion was in an early stage, but those charged with the responsibility of government were fully alive to the grandeur of its resources and its potential greatness. A vote of thanks was accorded to Sir William with acclamation.

## ELECTRIC TRAMWAYS IN HONG KONG.

Although little more than 60 years have elapsed since the island of Hong Kong became a British possession, its rise in importance, both as a commercial and naval centre in the Far East, has been both rapid and unique. Situated near the mouth of the Canton River, and distant about 90 miles from the ancient Chinese city of Canton, it possesses one of the finest and most beautiful natural harbours in the world. This must have been recognised by the Chinese themselves hundreds of years ago, as the Chinese characters representing the name of the island signify "Good Harbour." The island itself is some 11 miles long and from two to five miles broad, and consists of lofty uncultivated hills. In the younger days of the colony it was considered a most unhealthy place, owing to the virulence of malaria, but to-day the efforts of the Sanitary Board on the one hand and the Afforestation Department on the other have completely altered these characteristics. During the summer months the humidity of the atmosphere renders the heat very trying to Europeans, but from September to March the weather is all that could be desired. The population of Hong Kong is estimated at 284,000, and of these 274,500 are Chinese. Its trade is estimated at £50,000,000 per annum. It has excellent dock accommodation, is strongly fortified, and is the permanent naval base in the Far East.

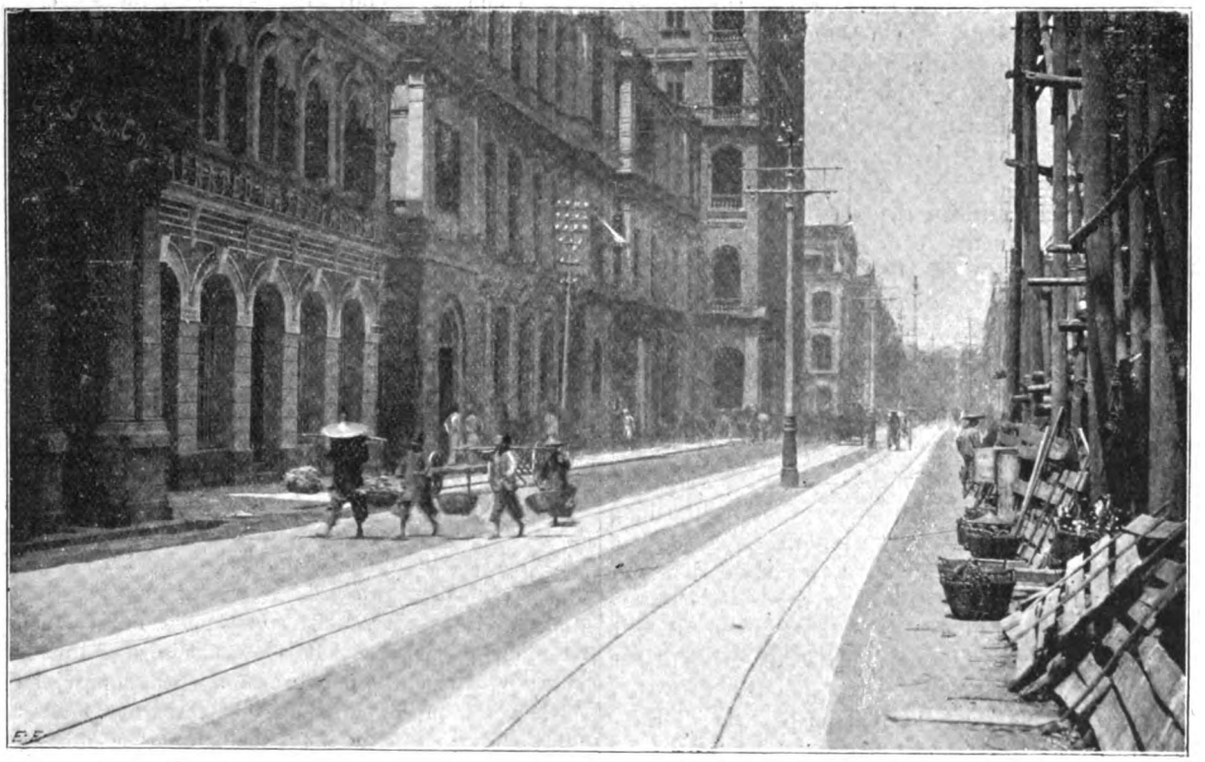

FIG. 1.—View of the Des Voeux Road in Hong Kong, showing Trolley Standards and also the Overhead Lighting Wires.

In 1902 an ordinance was passed by the Legislative Council of Hong Kong authorising the tramways to be laid down by the Hong Kong Tramways Electric Company, an English company with its headquarters in London, and work was commenced in May, 1903, and completed last July. The detailed plans and specifications were prepared by the company's consulting engineers, Messrs. Alfred Dickinson and Co., of Birmingham, who appointed Mr. Harold Hackwood to act as their representative in Hong Kong as resident engineer in charge of the construction. The contractors were Messrs. Dick, Kerr, and Co., of London, who carried out the whole of the work.

The total length of single track is 14½ miles, which is laid in 9¼ miles of route. The track is laid to a gauge of 3ft. 6in., with rails of the girder type, weighing 86lb. per lineal yard. Each rail joint is double bonded with 6/0 S.W.G. copper bonds. The lines within the city are laid for the most part as centre-pole construction (Fig. 1), but the eastern portion of the route being outside the city boundary, is laid as single line with passing places, and is equipped on the side-pole system. With the exception of a short branch line, which runs to the racecourse, the route runs parallel with the water front, and with the exception of a short length at Quarry Bay is practically level. At Quarry Bay a short length of road grading has been done, the original grade of 1 in 10 having been reduced to 1 in 15. Beyond Quarry Bay is the eastern terminus of the line, where is situated the small Chinese village of Shankiwan. Owing to the varying nature of the ground, three forms of permanent-way construction have been adopted. Where the ground was solid the rails were bedded on a concrete beam 18in. wide and 6in. deep; where the ground was not so good a bed of concrete 6in. deep and 7ft. 3in. in width extending under the whole track, and 1ft. 6in. on either side, was adopted. Over doubtful ground, which had been recently reclaimed from the sea, this concrete bed was increased to 8in. in depth. The concrete used was mixed in the proportion of 6 to 1, Portland cement of local manufacture and exceptionally good quality being used. After the rails and the bottom concrete were laid, the road surface was made up to rail level with concrete and finished off with a smooth surface to the proper camber of the road.

The overhead construction has been carried out in a very neat manner, the length of arms on the centre poles (Fig. 1) not exceeding 2ft., while the arms on the side poles vary in length, the majority of them being 6ft. long. The poles are of mild steel, 28ft. 3in. in length, 7in. in diameter at the base, tapering to 4in. in diameter at the top. They are set 6ft. in the ground in a solid block of concrete. Within the city ornamental base castings greatly add to the appearance of the poles, which are still further enhanced by the addition of wrought-iron scrolls on the bracket arms. The trolley wire is divided into half-mile sections by means of section insulators, and at each of these points the main feeder cables are tapped and current is taken to supply each section of trolley wire. This is accomplished by running the feeders through a feeder pillar containing the necessary switches and fuses, the connections from the feeders to the trolley wires being made with rubber-covered $^{37}/_{16}$ cables, carried up inside the poles and along the sides of the bracket arms. The pressure on the trolley wire is 500 volts. A lightning arrester is provided in each feeder pillar, and also a telephone giving direct communication with the power-house. The feeder cables were supplied by the Callender Cable and Construction Company, and laid on the solid system. In addition to the main feeders running east

Digitized by Google

and west from the power station, a return $^{37}/_{13}$ booster feeder has been laid in each direction to within a mile of the two distant termini, where it is connected to the rails. It also makes connection with the rails at each feeder pillar.

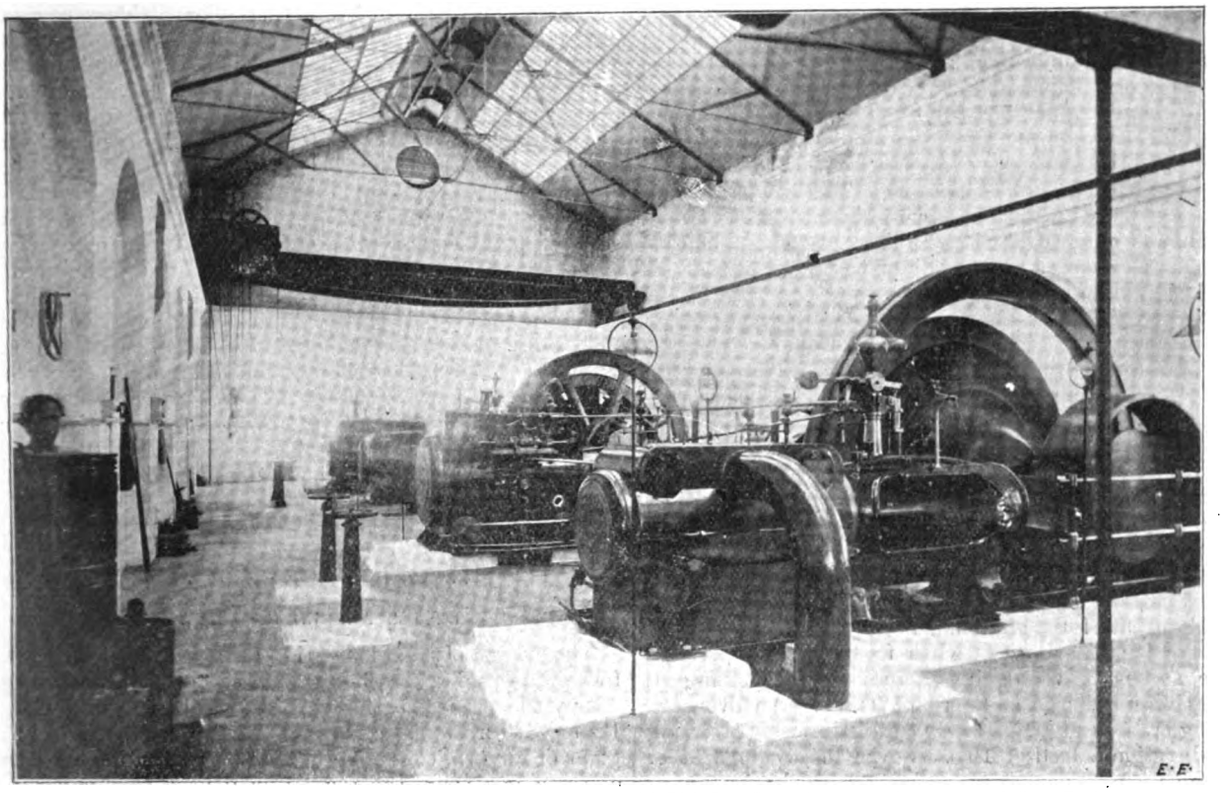

FIG. 2.—The Engine Room of the Hong Kong Tramway Station, with Dick-Kerr Generators coupled to Yates and Thom Engines.

A three-core pilot cable has also been laid from the power station to each terminus, one core being connected up for testing purposes and the remaining two cores being used for telephone service.

the fact that a very few years ago it was reclaimed from the sea, and consequently no good foundation could be obtained for either buildings or machinery. However, as it was the best site obtainable in all other respects, this difficulty had to be overcome, and efficient foundation were obtained by the driving of over 5,000 piles These were spaced so as to support the whole weight of the buildings themselves, the ground (which greatly varied in solidity) being left as an additional factor of safety. China fir poles, 15ft. in length and 5in. in diameter, were used as piles under the buildings and machinery, special 7in. poles, 18ft. in length, being used for the chimney foundations. The depôt comprises engine-room and basement, boiler-house and coal store, car-shed and machine shop, smithy,

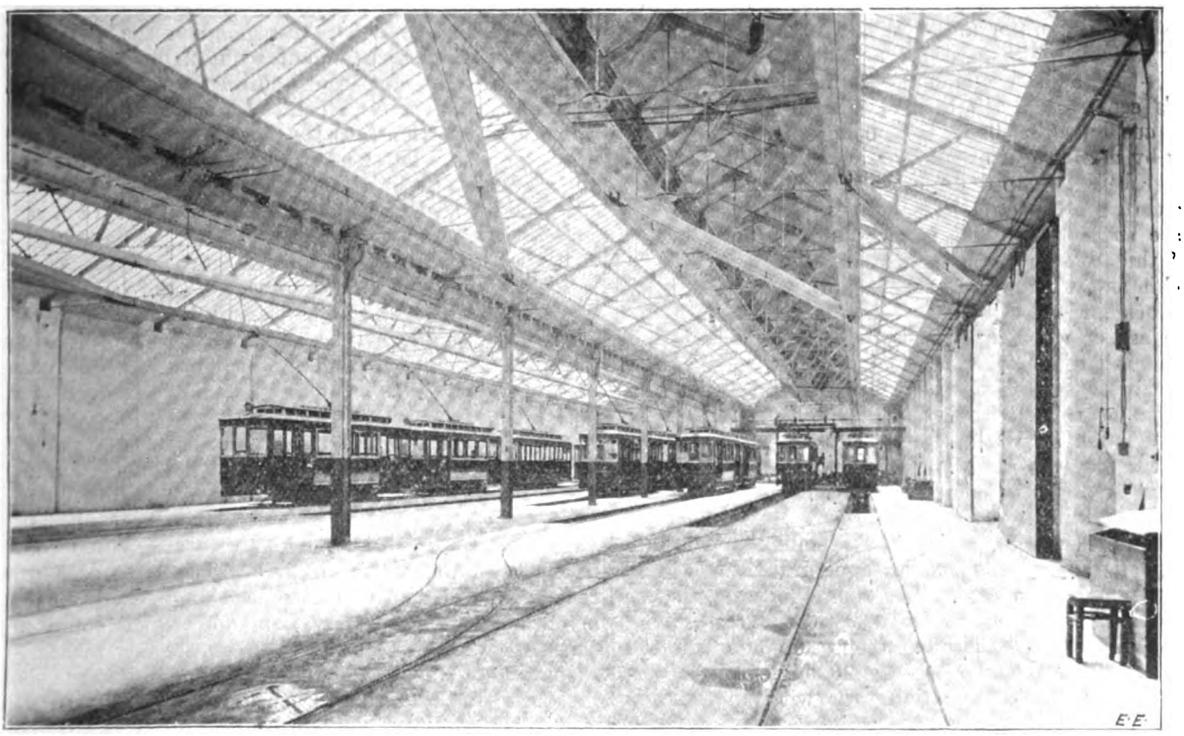

FIG. 3.—The Carshed at Hong Kong.

The generating station is as nearly as possible in the centre of the system, a convenient site having been obtained alongside the Bowrington Canal, from which water for condensing purposes is obtained, and which enables coal and materials to be delivered by barges direct on the site. The only objection which could be found with the site lays in

Digitized by Google

paint shop and carpenter's shop, and also offices. The engine-room (Fig. 2), which is lofty and well lighted, contains two Dick-Kerr continuous-current, direct-connected railway generators of the multipolar type, compound wound, giving a potential of 550 volts, and running at 100 revolutions per minute. They are designed to run either separately or in parallel. The generators are keyed direct on to the main shaft of the engines, which are of the horizontal cross-compound type, each engine being equal to a maximum load of 557 b.h.p. The engines, built by Yates and Thom, are each provided with a Wheeler surface condenser of the Admiralty pattern, and may be worked either condensing or non-condensing. The condensers are fixed in the basement below the engine-room, as also are all the steam and other pipes, thus leaving the engine-room free and open. Circulating water is obtained for the condensers from the Bowrington Canal, which is alongside the site, the water first passing through sumps fitted with gratings and strainers to exclude obstructions. In addition to the two traction sets there are two smaller plants for the arc and incandescent lighting of the depôt, one set being driven by a small high-speed engine, and the other by a motor running from the 500-volt circuit. The lighting circuit is supplied at 100 volts pressure. The switchboard, which is of Dick-Kerr's standard type, consists of nine panels. It includes a main station panel, two generator panels, two feeder panels, one Board of Trade panel, and three lighting panels. The main station panel contains recording instruments of the latest pattern, including a recording wattmeter showing the total output of the station. The Board of Trade panel is arranged for receiving test wires from different parts of the line, and is provided with instruments for making all the tests required by the Board of Trade. An overhead travelling crane is provided capable of lifting and traversing in any direction a load of 10 tons over the whole area of the engine-room.

The boiler-house, which is at a lower level than the engine-room, contains two double-drum water-tube boilers, of the Babcock and Wilcox type, arranged to burn ordinary Japanese engine slack. Each boiler has 3,654 square feet of heating surface, evaporates 12,000lb. of water per hour, and works at a pressure of 160lb. per square inch. In addition to the steam and water gauges, each boiler is fitted with a spring safety valve and a dead-weight safety valve. Water is supplied to the boilers by two Blake and Knowles feed pumps, which take water from either the storage tank or the hot-well, and feed the boilers either direct or through a Green's economiser. In case of mishap the economiser may be cut out, the flue gases being conveyed to the chimney by means of a by-pass or auxiliary flue, and the feed water being pumped direct into the boilers without passing through the economiser tubes. Two feed-water filters are supplied, and all water passes through one or other of these before entering the boilers.

The chimney, which is circular, is built of brick, and is 153ft. in height. As Chinese bricklayers are unaccustomed to this class of work, it presented greater difficulties in construction than any other part of the work, and as Hong Kong is subject to typhoons of noted severity, exceptional care had to be taken with both the foundations and the building of the shaft. With the exception of the foundations and the chimney cap, the whole of the brickwork is built in lime mortar of special composition, as is also the brickwork of the buildings.

The car-shed (Fig. 3), which is a rectangular building 220ft. in length, contains six lines of track and gives accommodation for 35 cars. The roof is of iron, in two spans, partly glazed and provided with louvres, giving plenty of light and ventilation. Inspection pits run the whole length of the shed. There are 26 single-deck motor-cars, 10 being of the combination type with an enclosed portion in the centre and an open platform provided with seats at either end. The remaining 16 cars are of the open cross-bench type. The over-all length of the cars is 29ft., the total width is 6ft. 6in., and the wheel base 6ft. 6in. The combination car has a seating capacity for 32 passengers, and the cross-bench cars for 48 passengers. Each car is mounted on a truck of the Brill type, and is equipped with Dick-Kerr 25A motors, and the standard metallic shield blow-out controllers and the usual hand brakes. The trolleys, which are of the lateral type and provided with a swivel head, are 16ft. 6in. in length, and enable the trolley wire to be fixed 10ft. away from the centre of the track where necessary. The car bodies were built at Preston by the Electric Railway and Tramway Carriage Company, and were shipped to Hong Kong in sections, where they were fitted together and connected up in a very short space of time. At one end of the car-shed is a well-equipped workshop, containing screw-cutting gap lathe, wheel lathe, wheel press, and drilling machines, the whole being driven by a 500-volt motor. A suitable smithy, carpenters' shop, and paint shop are also provided.

Before the introduction of electric traction into Hong Kong the popular ricksha drawn by a Chinese coolie was the principal means of locomotion, and of these nearly 2,000 were licensed for hire, in addition to a large number owned privately. Although rather slow, the ricksha is hard to beat for general convenience; the fight for supremacy between the out-of-date ricksha and the new electric car will be of interest, but must of necessity end in the victory of the latter. As this is the pioneer system of electric traction in China, it is to be hoped the venture will meet with a well-deserved success, and that electrically-equipped lines will shortly be laid in other parts of the Celestial Empire by English contractors.

## THE ELECTRIC LIGHTING OF RAILWAY TRAINS.

BY DR. ALFRED GRADENWITZ.

The system of electric lighting for trains described in the following was designed by Mr. Aichele, and is being brought out by the Aktien-Gesellschaft Brown, Boveri, und Co., of Baden, Switzerland. In this system each car has a lighting plant of its own, consisting of a dynamo, a storage battery of some few cells, the regulation device, conductors, and lamps. This will greatly increase the value of this system, which may be applied both to ordinary and express trains, as well as to international through trains on the one hand and mixed trains on the other. Only the conductors and lamps are arranged inside the cars, while the remaining parts (any one of which is self-contained and interchangeable) are located outside the wagon on the truck, so as to be easily accessible (see Fig. 1).

The dynamo, which is suspended in the middle of the truck, is a shunt machine of about 2 h.p., being enclosed in a dust-tight cast-iron housing, and driven from one axle of the wagon by a belt. Its speed will thus, in any case, be proportional to the speed of the train. On the direction of the latter being reversed, its poles are changed automatically by shifting the brushes on the commutator. The storage battery includes 9 or 2 × 9 cells of a capacity of about 140 ampere-hours, corresponding to a lamp voltage of 18 or 36 volts. The system may, however, as well be designed for any desired number of cells, and any voltage at the terminals of the lamp. Each set of nine cells is located in a box, and so as to be accessible at any time. They do not, however, supply current except at very low speeds of the train, as obtaining immediately before and after stoppages, and when standing in the stations themselves. The capacity of the cells may therefore be very small as compared with the output of the plant. Throughout the remainder of the run they receive charging current of an intensity that is independent of the speed of the train, while adapting itself automatically to the actual condition of charge of the storage battery. The latter, accordingly, remains permanently under working conditions most favourable for its preservation, and which could not be excelled even in the best of stationary plants. This regulation of the charging current according to the speed of the train and the charging conditions of the battery, as well as the connecting and disconnecting of the dynamo, is effected automatically by an extremely precise and reliable regulation device, which at the same time adjusts the voltage at the lamp terminal so as to prevent any increase in voltage resulting from the charging current. As a consequence of this, the lighting will not undergo any appreciable variation, either on the speed of the train being varied or on the passage of the train from the station to the track, and *vice versâ*. This regulator, which is fitted in a small

Digitized by Google

iron casing, may be either located outside on the truck, as shown in Fig. 1, or inside in the coach.

The internal arrangement of the apparatus is shown in Fig. 2, the essential parts being the switching apparatus, C,

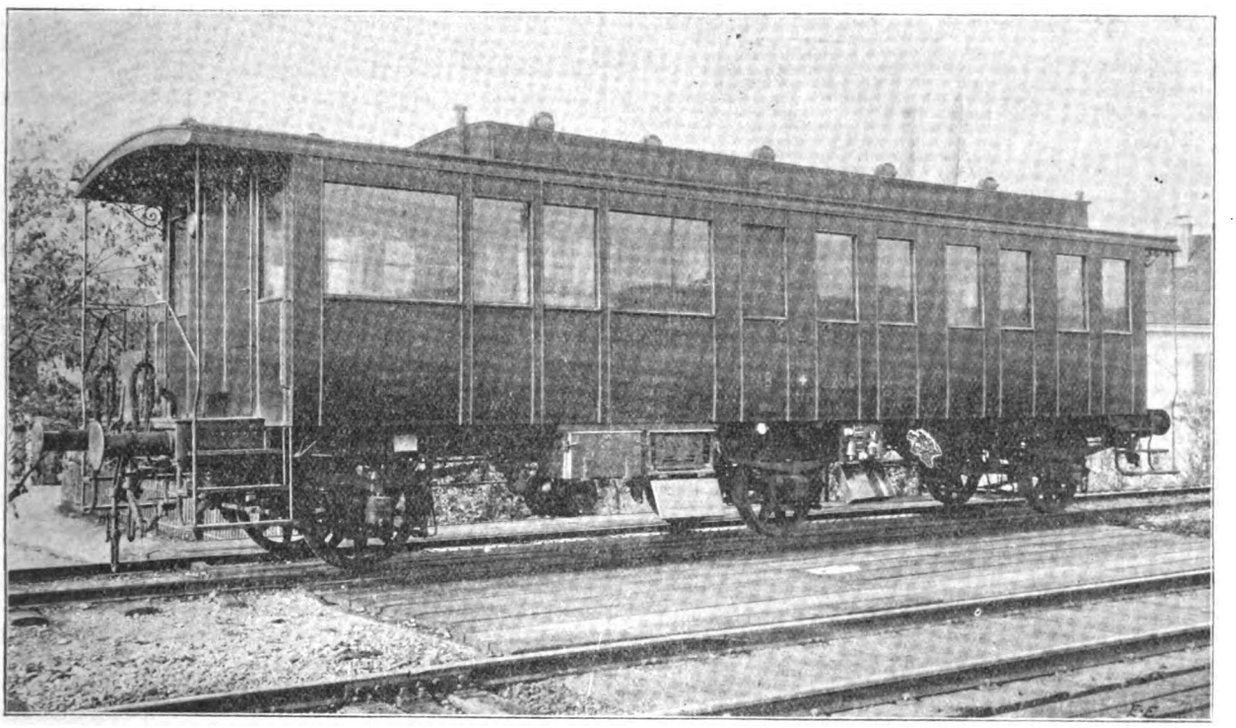

FIG. 1.—First and Second Class Passenger Car with Train-Lighting Outfit (apparatus below the car).

and the regulating motor, R. The latter consists of a bell-shaped electromagnet, including two independent coils—one of thin wire, which is permanently connected to the terminals of the dynamo, and one of thick wire, which is traversed by the machine current. If, under the magnetising action of these coils, the core of the apparatus be lifted, some fork-shaped copper springs, which are attached to the upper end of the core, will touch an opposite metal plate, thus completing the connection between the dynamo and battery. By a plate spring located sideways below these copper springs on the core of the apparatus there will be closed at the same time a second circuit serving for the purpose of regulation, as seen from the following. The core of the

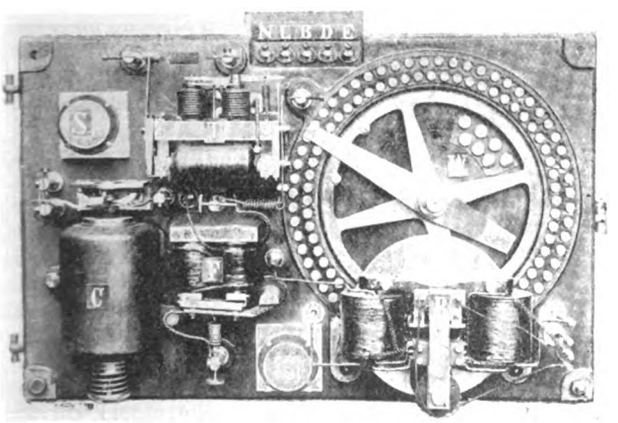

FIG. 2.—View of Regulation Apparatus, first design.

apparatus is raised under the influence of the thin wire coil, *a*, connected to the terminals of the dynamo (see diagram of connections, Fig. 3) or of the apparatus, C, as soon as the train exceeds a speed of about 15 miles per hour, when the voltage at the terminals of the dynamo has reached the battery voltage. The connection between the dynamo and the battery will accordingly be effected without any sparking, thus ensuring a permanent preservation of the contact points. On the speed of the train being further increased, the battery will begin to be traversed by the charging current, passing through the second coil, *b*, of the switching apparatus, C, where it acts in the same way as the current in the coil, *a*, thus securing the automatic adjustment of the shunt regulation resistance of the dynamo which controls the current supplied by the latter. To this effect a small toothed wheel mounted on the motor axle is made to engage with a smaller one that is connected to the lever, H, of the shunt regulating resistance of the dynamo. On the armature being rotated (which occurs at slow speeds only while the regulation is being effected) the lever, H, will slide on the circular resistance contacts, these movements being damped by an aluminium disc mounted on the motor shaft and located in the field of an electromagnet.

The motor magnets bear three independent exciting coils, marked I., II., and III. respectively in Fig. 3. As long as there are no lamps switched in, the coil I., traversed by the machine current, and III., which is applied to the battery terminals, will work simultaneously. If any lamps are thrown in, the coil III. will be replaced by the coil II., which is traversed by the lighting current, so that the coils I. and II. now work simultaneously. Under the action of I. the lever, H, will be displaced so as to effect an increase, and under the action of II. or III. a diminution of the resistance in the exciting circuit of the dynamo. In both of these cases the lever, H, will thus be adjusted under the influence of two magnet coils of the regulation motor, acting in opposite rotary directions, so as to weaken the excitation of the dynamo as soon as the effect of the coil I. traversed by the machine current becomes the stronger, on account, for instance, of an increase in the speed of the train. The lever, H, will then slide on the contacts of the shunt regulation resistance, E, as the speed of the train increases until the effect of the coil I. corresponds accurately to the effect of the coils II. or III., thus balancing the latter. If this state of equilibrium is attained, the motor will remain at rest until, on account, for instance, of a decrease in speed, the equilibrium of the two magnetising coils of the motor is once more disturbed, when the motor, under the influence of the now prevailing coil II. or III., turns the lever at the regulation resistance in an opposite direction, so as to increase the excitation of the dynamo, until the charging current traversing the coil I. has returned to its previous value, thus re-establishing the equilibrium between the coils I. and the antagonistic coil. This arrangement will thus regulate the machine current, and accordingly the charging current, with any speed of the train, so as to cause the coil I. traversed by the same to exert an effect

Digitized by Google

which always accurately corresponds to the effect of the coil III. or the coil II. By applying to the coil III. the voltage of the battery, there is thus obtained, in the first case, a regulation to constant intensity of the charging current, while, in the second case, by causing the lighting current to traverse the coil II. the charging current is adjusted automatically in accordance with the lighting current, and at the same time the increase or decrease of the latter charging current is regulated by increasing or decreasing by steps the effect of the coil II. (traversed by the lighting current), through a gradual modification of a resistance inserted in parallel. To this effect, the contacts of the resistance, W, connected in parallel to the coil, are so arranged as to be touched by the lever, H, on its first or last movement, thus increasing or decreasing gradually the resistance, W. In a similar way the two electromagnets, F and T, throw the coils II. or III. out of action, partly or completely, thus effecting an adjustment of the regulation apparatus to a very small charging current.

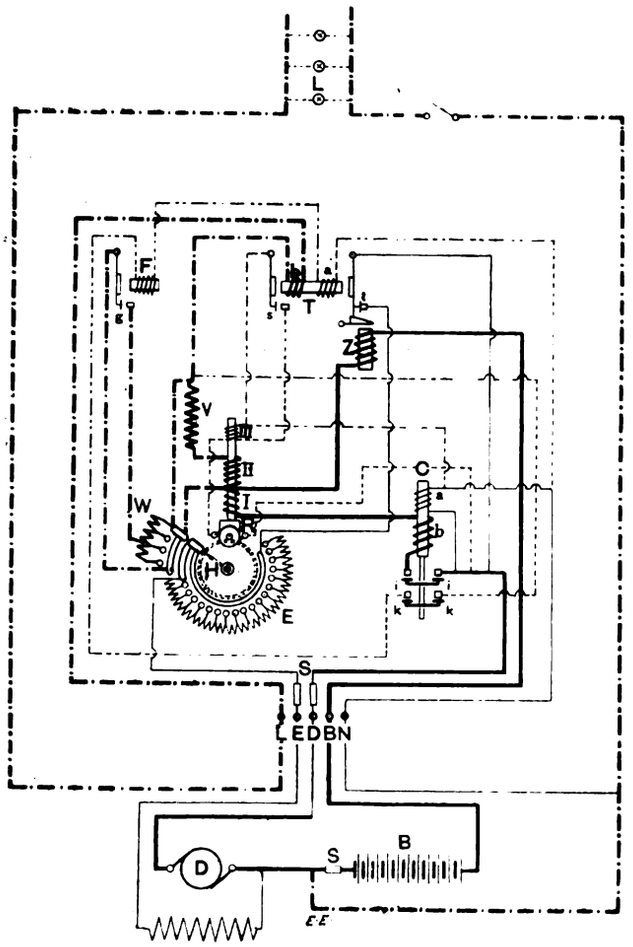

FIG. 3.—Diagram of Connections.

In addition to the above appliances, the housing of the regulation apparatus contains two safety fuses for the main and shunt circuits of the dynamo respectively, as well as a device for automatically interrupting the excitation circuit of the latter. The purpose this device is intended for, as well as the common working of the remaining parts (already alluded to) of the regulation mechanism, will be seen from the following: During the stoppage of the train the connections between the dynamo and the battery, B, will be interrupted in the switching apparatus at *i i* (Fig. 3), when the lamps derive their current from the accumulator battery. The lever, H, has been placed during the preceding stoppage of the train, owing to the action of the coils II. (traversed by the lighting current), on the magnet of the electromotor, R, in the extreme position shown in Fig. 3, where the shunt regulation resistance and the coil II., inserted in the lighting circuit, as well as the shunt resistance, V, before the lamps, are short-circuited. The lighting current will, therefore, in the beginning exert no magnetising effect on the magnets of the electromotor, R, the lamps being applied to the battery terminals without any shunt resistance. The relay, T, having attracted its armature under the influence of the coil *b*, traversed by the lighting current, the contact will be completed, and the coil III. will be out of action.

On the train starting there will, as soon as the speed of the dynamo has become sufficiently increased, a dynamo voltage equalling the voltage obtaining at the terminals of the battery, when the magnetising effect of the coil *a* in the switching apparatus, C (which is being permanently applied to the terminals of the dynamo), suffices to lift the core of the apparatus, thus completing the connection between the dynamo and battery. The corresponding speed of the train is about 15 miles per hour. If the speed increases further, the tension at the terminals of the current generator will be augmented so that the battery is traversed by a charging current. This current, traversing the coil *b* of the switching apparatus, C, will act there in the same sense as the current in the coil *a*, that is to say, will secure the connection between the dynamo and battery that has been effected by this coil. In addition, the charging current will, however, traverse the magnetising coil I. of the electromotor magnet, turning the lever, H, from the extreme position to the nearest contact of the resistance, W. Instead of the short-circuit, part of the resistance, W, will now be placed in parallel to the coil II. and the shunt resistance, V, when part of the lighting current traverses the coil II., which by its magnetising effect balances the coil I. traversed by the charging current, so that the lever is stopped in this position, until on account of the increasing speed of the train the effect of the machine current in

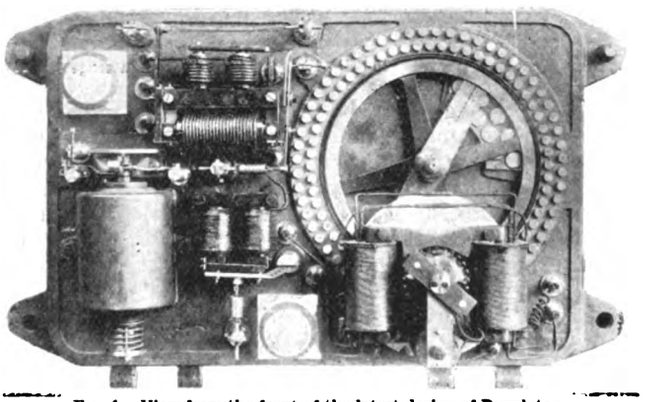

FIG. 4.—View from the front of the latest design of Regulator.

the coil I. becomes stronger. Then the lever, H, turns on to the second contact of the resistance, W, thus altering once more the distribution of the lighting current in the two parallel branches so that the portion traversing the coil II. and the shunt resistance, V, becomes greater and compensates for some moments the machine current traversing the coil I. The lever, H, will thus stop also in this second position for some moments until the machine current becomes sufficient to move it on. During the increase of the charging current the lever, H, thus slides slowly over the various contacts of the resistance, W, while the portion connected in parallel to the coil II. and the shunt resistance, V, increases continually until it becomes infinite, when the lever, H, has left the contacts of W. The shunt resistance connected to the lamp, and which consists of two parallel branches (coil II. and shunt resistance, V, on one side and inserted portion of resistance, W, on the other) will thus be increased by steps which are adjusted automatically according to the actual intensity of the increasing charging current. The fall in voltage undergone by the fixed lighting current in this variable combined resistance thus corresponds at any moment to the increase in voltage at the battery terminals, due on one side to the disappearance of the discharging current, and on the other to the increase of the charging current. The charging current is thus thrown in and augmented without any oscillation in the luminous intensity of the lamps, though the same battery be simultaneously applied to the lamps and connected to the dynamo. After the lever, H, has left the contacts of the resistance, W, on the train being further accelerated, the full amount of lighting current will traverse the coil II. The adjustment of the lever is effected by the simultaneous

Digitized by Google

action of the two antagonistic coils, I. and II., which are traversed by the machine and lighting current respectively. The zero position of the lever with the various speeds of the train corresponds always to an intensity of the charging current that bears a constant ratio to the intensity of the lighting current. The former will, therefore, undergo an alteration only in the case of the number of lamps inserted being altered, increasing and falling along with the lighting current.

Some important advantages in operation are due to this arrangement. The fall in voltage produced by the lighting current in the shunt resistance connected to the lamps will always be accurately compensated for by the increase in voltage produced by the charging current at the terminals of the battery, so that in the present system, in opposition to other schemes, the lamps can be switched off or in at will without having to be replaced by compensation resistances to keep the voltage at the remaining lamps constant. For the same reason, there will on a lamp burning out be no increase in voltage on the remaining lamps. At the same time, however, there is obtained an operation as economical as possible, as any losses of energy in compensation resistances are avoided. The ratio of the number of turns in the two coils I. and II. is so designed that the charging current traversing the battery remains in any case below the admissible limit. Especially in express trains which traverse great distances without any stoppages, the battery will frequently approach a completely charged

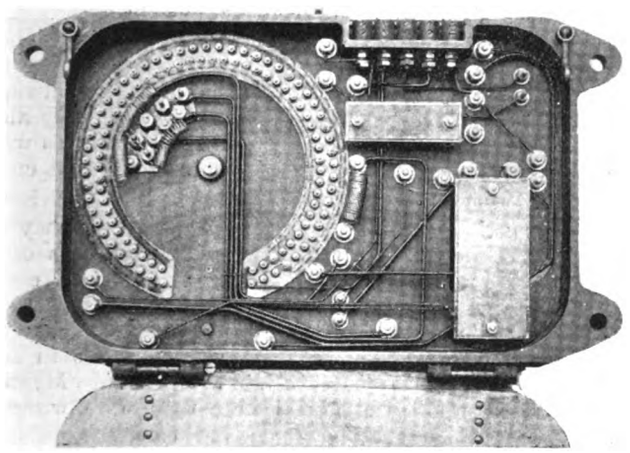

FIG. 5.—Back View of Regulator of the latest design.

condition. When under the influence of the increasing charging voltage, the electromagnet, F, will attract its armature, inserting, in virtue of the contact, *g*, part of the resistance, W, which is connected in parallel to the coil II., when the latter is no more traversed by the full amount of lighting current, but only by part of the same, so that the current in the coil I. of the magnitude of the lighting current suffices to compensate the magnetising effect of the coil II. The lever, H, accordingly moves into a zero position corresponding to these conditions, while the coil I. is traversed only by the lighting current supplied from the dynamo, the battery receiving no charging current, so that its voltage decreases This alteration will, however, not be felt in the lamps, as by the insertion of the resistance, W, the total resistance connected to the lamps has undergone a corresponding diminution. The increase in voltage obtaining in the last stage of charging at the terminals of the accumulators will thus not be felt in the lamps, while at the same time any regular overload on the battery is avoided. Should any decrease in battery voltage be produced on account of the current supplied from the accumulators in the station, the electromagnet, F, would release its armature, thus opening the contact, *g*, of the resistance, W, so that in the subsequent journey there is an instantaneous charge of the battery with a corresponding increase in the shunt resistance connected to the lamps.

In case the running speed decreases, the electromagnet would, under the magnetising influence of the constant lighting current, first move the lever, H, into positions corresponding to the smaller resistances in the shunt circuit of the dynamo, until the lever, H, has reached the contacts of the resistance, W, when the resistance is connected in parallel to the coil II., and the shunt resistance, V, so that the same process as on the starting of the train occurs in an inverse order—namely, a slow decrease of the charging current occurring by steps and being accompanied by a step-by-step diminution of the shunt resistance connected to the lamp. The charging current will have disappeared completely after the lever has returned to the first contact of W, when in the switching apparatus there will only be left the attracting effect of the coil *a*, which just suffices to maintain the core of the apparatus in the attracted position. The voltage of the dynamo has again reached the value with which the core of the switching apparatus, C, was attracted, thus being equal to the accumulator voltage. In the subsequent moment the dynamo voltage will, on account of the further decrease in the speed of the train, fall below the voltage of the accumulator battery, the core of the switching apparatus, C, dropping so as to discontinue the connection between the dynamo and battery. This decrease in the charging current and break in the connection between the dynamo and battery occurs without the luminous intensity being altered to any appreciable degree. During the lighting period the battery thus receives charging current as soon as its state has become different from the condition of perfect charging, while at the same time,

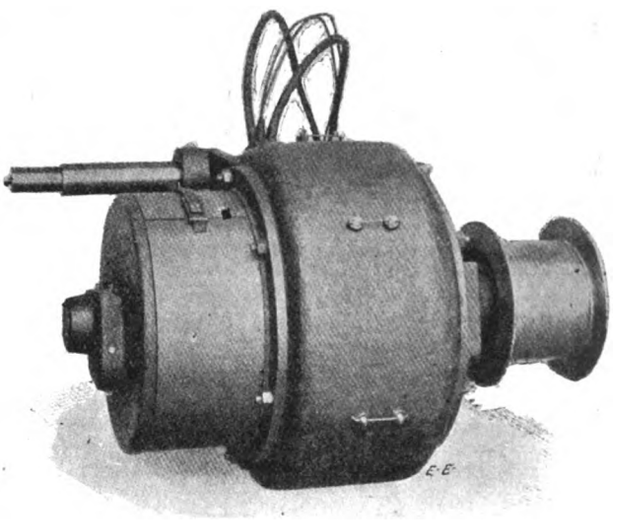

FIG. 6.—Direct-Current Dynamo for Train Lighting.

the lamp current is supplied from the dynamo. The charging current is maintained constant independently of the speed of the train, being altered only in case the number of lamps is altered. Its magnitude is readily adapted to the most different conditions of operation by grading the effect of the coil traversed by the lighting current on the motor magnet by a permanent connection in parallel of part of the resistance, W, to the coil mentioned above.

As soon as the perfect charge of the battery has been attained, the charging current disappears automatically, any switching made for its regulation occurring automatically and exerting no appreciable influence on the candle-power of the lamps. When all the lamps are switched off the lighting circuit the effect of the coil *b* on the core of the apparatus, T, will accordingly disappear. The armature of this apparatus remains, however, in an attracted position under the influence of the coil *a*. As soon as the train has reached a station, the circuit, including the latter coil, is interrupted by the switching apparatus, C, so that the armature of the apparatus, T, being released will open the contact, *s*. The coil III. on the magnets of the electromotor, R, will thus be actuated so that in the subsequent journey of the train the motor under the action of this coil (which is applied to the battery terminals) and the coil I. (which is traversed by the charging current), regulates the charging current so as to maintain it constant independently of the speed of the train. Before each stoppage, the switching apparatus, C, discontinues the connection between the dynamo and battery, re-establishing it in the subsequent journey. As the complete charge of the battery is reached, the increase of voltage obtaining in the final charging condition at the accumulator

Digitized by Google

terminals will be sufficient to produce the attraction of the core of the electromagnet, T, thus completing the contact, S, and discontinuing the effect of the coil III. on the magnet of the electromotor. The latter will accordingly, under the action of the magnet coil I. (which is traversed by the charging current), adjust the field excitation of the dynamo to smaller values until the charging current has disappeared completely. Any supply of energy by the dynamo will thus be discontinued, while at the next station the switching apparatus, C, interrupts the circuit of the coil *a* at the contacts *k*, so that in the subsequent run the coil III. on the motor magnet is switched in once more, the electromotor adjusting accordingly once more to the normal charging current intensity, in case any consumption of current from the battery has taken place during the stoppage. The present regulation system thus regulates the charge of the accumulator battery in the same way as in a stationary plant.

Any overload of any parts of the system is prevented in the normal course of operation by the very efficient automatic regulation. In order, however, to protect the apparatus against the occurrence of any excessive current intensity, safety fuses, S, have been inserted both in the dynamo main and shunt circuits, and in the battery circuit. In addition, a special safety device has been connected to the system, preventing in the event of any disturbance of the regulation resulting from an interruption in the battery circuit (as might arise from the breakage of a connecting plate between two cells), the voltage of the dynamo from reaching any figure prejudicial to the lamps. The electromagnet, T, is fitted with a second armature, the spring of which is so adjusted that only the effect of the coil *a* resulting from an overload, in conjunction with an increase of current in the coil *b*, will be sufficient to overcome its tension. In this case the exciting circuit of the dynamo is interrupted at *t*.

Some tests of this train-lighting system were made with a registering voltmeter of Elliott Bros., and a hot-wire ampere-meter of Hartmann and Braun, on a car of the Zürich-Chur express train. The speed of the train was measured by means of a Klose speedmeter. From the records obtained, it is clear that the maximum variations in the lamp voltage did not exceed ±0·4 volt, while the current from the dynamo remained constant to within about ± five amperes.

## ELECTRICITY IN INDIA AND BURMA.

BY E. C. DEEPHOLT, A.I.E.E.

It has often struck me, as a young Anglo-Indian engineer anxious to see the success of the electrical industry not only in the mother country, but also in his own, why British manufacturers are and have been so backward in endeavouring to initiate the manufacture of electrical machinery, apparatus, cables, etc., by opening branch factories in far Eastern India.

It would be too long a subject to venture to discuss or narrate fully, and, consequently, ere I proceed I desire to impress on my readers that the attempt I have made is only to give a brief account of the gradual progress of electricity at the present day as well as its great future in India and Burma, adding a few items which may interest my brother engineers in this country. By so doing I hope it may be a means for future discussion and consideration amongst British manufacturers, which may lead to making the Indian Empire some day equal to any other in the electrical world. There is no doubt that the experiment would be welcome as well as meet with success; nay, be a boon to the country were a few of the British firms to start manufacturing in this country. For when one comes to consider the charges for freight, duty, packing, carriage, etc., and other items of expense, which necessarily must occur by the present system, there are grave reasons why people in India are somewhat reluctant to invest in large schemes for improvements which this great power affords us.

Although, on consideration of the short time England has had towards the civilisation of the country, the success of electricity and its use has been paramount. In order that I may give a fair idea of the same I thought it would be better to dwell on each Presidency of the Empire individually, by noting a few of the more important undertakings.

*Bengal.*—Commencing with Bengal, it is very pleasing to see how great and rapid has been the demand for electricity lately in this vast Eastern Presidency, and how it has risen to the front, not only with up-to-date machinery but also with more than there is in any other part of India. In Calcutta, already the success of the new electric tramways, introduced by Messrs. Dick, Kerr, and Co., London (a British firm which has not only set the example but has also earned a great reputation in the East), has been marked, and the extensions in progress and under consideration are very numerous. The demand for electricity by private consumers for use for fans, light, and power may also be interesting to note. It is so much that a second, and even a third, supply station has had to be built by Messrs. Kilburn and Co., Calcutta, in the districts of Alipore and Howrah, to meet the demand. In these, no doubt, Crompton's machines and Babcock and Wilcox boilers are rendering loyal service, each in their respective capacities; and there is every hope to see in the near future at least all the principal thoroughfares bright with the rays of the electric light. Several other large schemes in Howrah and on the banks of the Hooghly are being carried out with success. Darjeeling, the great hill station in the Himalayas, as well as Dacca, have resorted to electric light installations, and several other towns and districts in Bengal are about to follow suit by introducing electric tramways and lighting of the principal thoroughfares. Large railway workshops, mills, factories, coal and gold fields, and irrigation works, for which India has always been noted, are anxiously awaiting the day when they also may be worked more favourably and scientifically, as well as with less expenditure for maintenance and initial cost, by up-to-date electric installations.

*Madras and Mysore.*—Turning now to the Presidency of Madras and the independent State of Mysore, it is only fair to state the very great good the American engineers of the General Electric and British Thomson-Houston Companies have done, and how they have carried everything before them in the southern states in the electrical line. The valuable gold mines of Mysore have yielded wonderful profits since they were worked electrically, the power being derived from the natural waterfalls of the Cauvery, and the current transmitted by overhead conductors over miles and miles. Lately very large schemes have not only been contemplated but undertaken for the further development and use of this great power in the adjoining districts. Bangalore and the city of Madras, which latter has already electric traction, are about to be improved by the introduction of a larger system of tramways, as well as for the supply of electric lighting. Even the Nizam's Government of Hyderabad has acknowledged its benefits, and consequently sanctioned certain concessions towards the introduction of its use within his dominions.

*Bombay and the North-West Provinces.*—Although these two presidencies have been somewhat behind and slower in acknowledging the benefits of this vast power by practical application, yet one cannot help remarking that the day will not be far distant when both shall be on a par with their sister states in the south and east. For lately visible signs and efforts are in course in the former's capital, and the triumph of the electrical installation laid in the Great Mogul city at Delhi by Messrs. Kilburn and Co., of Calcutta, on the occasion of the King's coronation, will be unsurpassed for some time in India. Great credit is due to Major Joly de Lotbiniére, who has spent much time on various schemes for the improvement of the Indian Empire, in this particular branch, and there is no doubt that Mussoria and Simla, two great hill stations, will meet with the necessary sanction of the Indian Government to carry out their proposed schemes. There is also great hope of seeing the electrification of the Kalka-Simla Railway, for which there is every possibility at no distant date, as well as the electric lighting of Kashmir and the great Amir's capital in Afghanistan and several important military districts in the Punjab.

Digitized by Google

*Burma.*—Last, though not least, comes Burma, which means to hold her own against any state in India in the utilisation of electricity, as well as in everything else. Again Messrs. Dick, Kerr, and Co., London, were the first in the field by introducing electric traction at Mandalay, whilst Rangoon intends electrifying her tramway system, as well as introducing electric lights along all the principal streets of the town. And one may feel confident, with the extravagant and luxurious desires of the Burmese gentlemen, there will be in a very short period of time an exceptional demand for electricity both from private installations and from public mains. It may also be well to state that the Burma ruby mines, which did not work very well at first, have of late years been most successful after the working of the same by electricity, the plant for which was supplied by Messrs. Johnson and Phillips, of Old Charlton, Kent.

*Education of Engineers, etc.*—Although it may be somewhat out of place to introduce the point of education into this subject, yet, on second consideration, I thought it would be interesting to say a few words on the subject with reference to the training of enginers, more especially on account of reading a few of the recent great discussions on the subject in various electrical papers. It needs the pen of Rudyard Kipling to describe the great success of the education of the natives of India. These are, no doubt, under great debt to the Indian Government for the very grand opportunities afforded them, both rich and poor, by the introduction of not only free schools and colleges, educational and technical, but also such big institutions for engineering as are at Roorkee and Silepur, which may be compared favourably with any in the United Kingdom for a thorough, complete practical and theoretical training and foundation in engineering before the launching out of a young man into the world. I shall take, *e.g.*, the Civil Engineering College, Silepur, and describe briefly the engineering department, manned by a large staff of English professors, who have qualified in the best English colleges, such as Cooper's Hill, Cambridge, and Oxford, each in his particular branch. It admits annually a certain number of students, rich or poor, native or Anglo-Indian, on free, reduced, or full fees, according to his parents' position and his own qualifications before entering. Equal opportunities are afforded to all, although the natives reside in separate blocks of buildings from the Christians, and there is no distinction between rich and poor amongst either class. Before the student is qualified to call himself an engineer of the college, he has to remain three, five, or even more years if he is determined to pass. The training he receives is not purely civil, mechanical, or electrical individually, but is a combination of the fundamentals of the three together, which is compulsory at the present day. So that when leaving college for service in the Indian Public Works—for which the training at the college is principally adapted—or anything else, he has had a good, sound, practical foundation in engineering, and may then choose any special branch most suitable to his experience in years to come.

*Details.*—He has to pass a strict annual examination in both practical and theoretical work, besides gaining a certain percentage every month; if he fails to pass he is obliged to leave the college for good and look for something else perhaps more suitable to his abilities than engineering. In the practical work the course consists of a severe test in the blacksmith's, carpenter's, and fitter's shops, after about nine months' training in each; besides, he spends some time in the turner's, moulder's, and boat-building shops, under suitable and capable foremen. For theory, he has the laboratories—physical, chemical, electrical—the lecture-rooms for mathematical and engineering subjects, in which all young engineers should have a good and thorough foundation; the drawing class, where plan, machine, and geometrical drawing is taught, besides which sketches and measurements of machines, houses and bridges, etc., have to be taken from typical examples, to be drawn to scale and painted. And last, though not least, he has to pass in estimating, and on the field in a complete course of surveying and levelling with different up-to-date instruments. For the encouragement of which, a prize is awarded to the best party of seven students who on being sent out to a different district, up country, lays out and plots the most accurate and best road or railway project, as the case may be.

In former years it was chiefly the aim of the college to train students for service in the Indian Public Works, but, owing to large and extensive improvements lately, thanks to the principal and staff, as well as to the Government, it gives the young engineer a further chance by affording the six senior students of the college, in order of merit, every year, the working and running of the college electrical plant, consisting of gas, steam, and oil engines, with direct and alternating current machinery, so that he may have a fair idea of electricity before he launches out into the world to gain experience and compete against his brother who has served his five years wholly in a workshop or dockyard. As electricity is at present only in its infancy, and there are very few facilities to gain experience at the present day in India, young college men who wish to get on have to visit the mother country or any other to enlarge their knowledge on electrical matters; whilst the man from the shop goes to sea to become a marine engineer. It will, therefore, be a great day and a boon to young Anglo-Indian engineers who are anxious to improve themselves in electrical matters, when British manufacturing firms set up branch factories in India.

Returning again to the subject, it would be well to mention a few of the principal advantages of the experiment, and leave men of experience to discuss its possibility in the near future. Compare the cost in labour between the native and British workman, for be he fitter, moulder, journeyman, carpenter, engine-driver, cable jointer, blacksmith, wireman, or labourer, or anything else, it is wonderful to note that the former is satisfied with on the average 25 per cent. of the wages which the latter would accept. Consequently initial cost and maintenance would be decreased a great deal. If such big firms, factories, and ironworks as are on the banks of the Hooghly and elsewhere, as Messrs. Burns, Jessops, and the railway workshops at Jamalpur, besides various other industries and factories, have proved successful, why should not the electrical industry, though perhaps needing a much greater initial cost, meet with as good a result? It would have the advantage of the help of the parent firms in England to enable it to supply the great demand in India, where water power is plentiful, land is cheap, and so is unskilled labour. The native workman is, however, easily trained. It is to be hoped that some day British subjects in India may be able to boast that in electrical manufacturing and the applications of electricity they can compare favourably with any other nation in the electrical world.

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

(*Continued from page 24.*)

An American switch of this type is shown in Fig. 5, and in this case the breaks are at right angles to the operating handle instead of parallel, as in the previous instance. A different system of operating is also employed, the pull on the main rod being obtained through a short lever with three points, one pivoted to the switch case, another to the handle link, and the other through a long link to the top of the rod carrying the main contacts. This switch has a normal capacity of 3,000 kw. at 1,500 volts. If installed in compartments it will break 8,500 kw. on emergency, but if placed on a switch panel, up to 5,000 kw. will be opened successfully. In Fig. 6 the switch in a modified form can be seen, arranged for overload tripping coils. The switch in this case will only deal with smaller loads. Its normal capacity is 800 kw. at 7,500 volts, but in emergency it will open circuit 2,500 kw. without trouble. The above switches are made by the General Incandescent Arc Light Company, of New York, to whose electrically-operated switches reference will be made later.

Another switch of this type is shown in Fig. 7 (the oil-tank is not included), and the same overhung arrangement of contacts will be noticed. A heavy cast-iron support is

Digitized by Google

fitted with substantial insulators holding the fixed contacts, and a compact system of operating levers is used to connect the contact beam with the handle. The contact bridges are fixed in horizontal insulators with large creeping surface, the supporting rod being clipped on at the centre of the bridge. Renewable spring clip contacts are fitted.

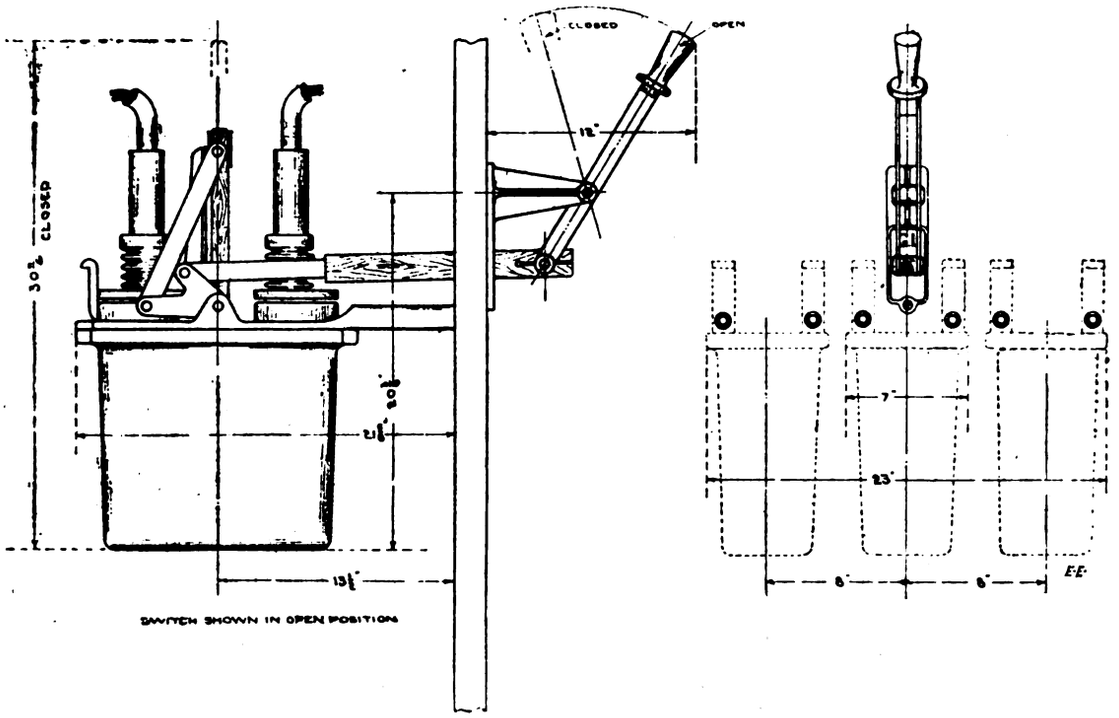

FIG. 5.—Box Oil Switch (American Type).

A larger switch of somewhat similar design is illustrated by Fig. 8, and, in addition, a special synchronising switch is fitted behind the main switch, thus coming into operation when the handle is raised to "half-cock." These switches are made by Witting, Eborall, and Co., Limited, and reference is made to their lay-out in board form later. They are fitted with automatic tripping coils (except Fig. 7) and are connected by bridge pieces depending from vertical rods coupled by a cross-beam above the terminal base, and fitted with a heavy weight sliding on parallel rods. The weight is provided at the back with an extension piece which projects over a catch controlled by a tripping solenoid. When the switch is closed, the weight is raised with some little play between it and the cross-beam. The weight

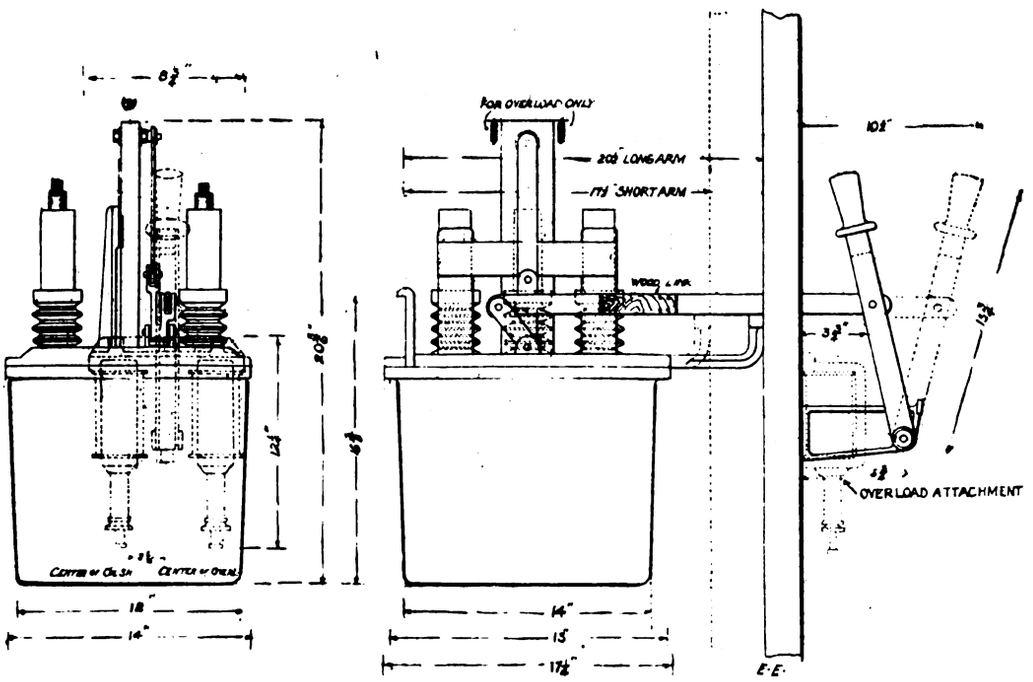

FIG. 6.—Box Oil Switch, with Overload Release.

placed one on each side of the handle, as shown in Fig. 9. In this the release trigger and adjusting screws for the plungers can be seen. The switch can be opened by closing the hand on both handles, drawing them together as one, and pulling both downwards. The synchronising notch is visible about half-way up the slot in which the handle lever travels.

A lever-control switch for high-pressure work has recently been introduced by Dick, Kerr, and Co., Limited. This is illustrated in Fig. 10, and will be noticed as embodying several novel features. The switch proper is not mounted directly behind and on the marble slab, but is supported on cast-iron legs with openings back and front for inspecting purposes. The fixed contacts overhang the oil-bath, when released by the trip coil, falls, and strikes the switch smartly out of its contacts. The weight has an advantage over springs, in that it does not fatigue like the latter when compressed for a long time in use. The action of the switch can always be relied upon where weights are used. The oil-box is divided into compartments, and arranged to be lowered clear of the contacts by a winch and handle. The operating handle is placed some distance

Digitized by Google

from the switch itself, being coupled to it by levers and cranks. The handle moves in a slot, and is held in the

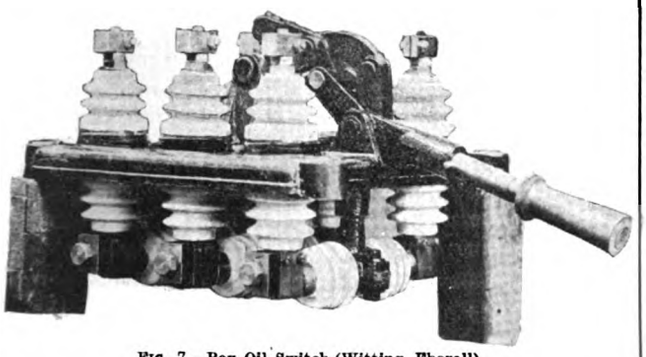

FIG. 7.—Box Oil Switch (Witting, Eborall).

"on" position by a spring bolt dropping into a slot at the end of the sector. This belt is withdrawn when

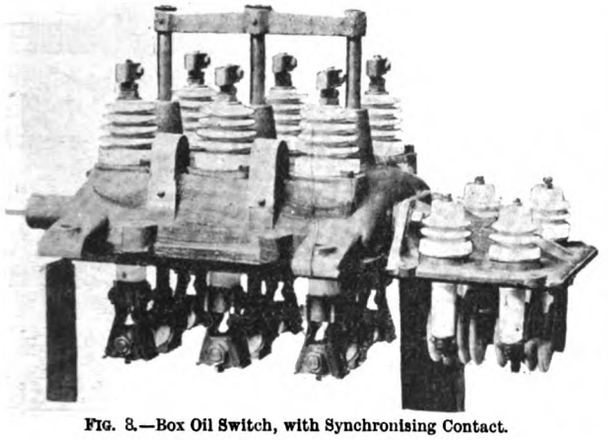

FIG. 8.—Box Oil Switch, with Synchronising Contact.

opening the switch by hand, the weight being released as with the tripping coil. The small switch above the handle is for closing the coil circuit when the switch must be opened in emergency. No-voltage and overhead releases can also be fitted to this type of switch.

*(To be continued.)*

## THE PURIFICATION OF WASTE LUBRICATING OIL.

BY F. H. DAVIES.

The purification or filtering of lubricating oil is one of those minor engineering economies that are so easy to make and tend so much in the long run to the reduction of costs. Considering the price of oil and the proportion that it bears to total works costs, one might expect that few would be found to dispute its utility; and yet the small outlay that is entailed by the installation of some suitable device to deal with dirty oil is often deemed unwarrantable or not absolutely necessary, with the result that an entirely preventable waste goes on that in a short time costs much more than the apparatus that would have obviated it.

Doubtless much of this apathy on the part of some power users has been encouraged by the introduction of the self-oiling bearing, which, if large enough, to a great extent acts as its own purifier by a settling process. But

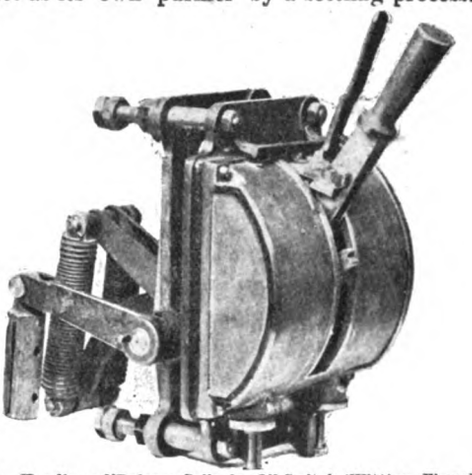

FIG. 9.—Handle and Release Coils for Oil Switch (Witting, Eborall).

such bearings become dirty in time, and in any case they only form a small portion of the lubricated surfaces in power installations using engines; consequently all the oil that finds its way from drip and siphon lubricators to the crankpits, etc., is absolutely lost, although perhaps quite fit for further use but for a little dirt that may easily be eradicated. In all but the largest installations the subject

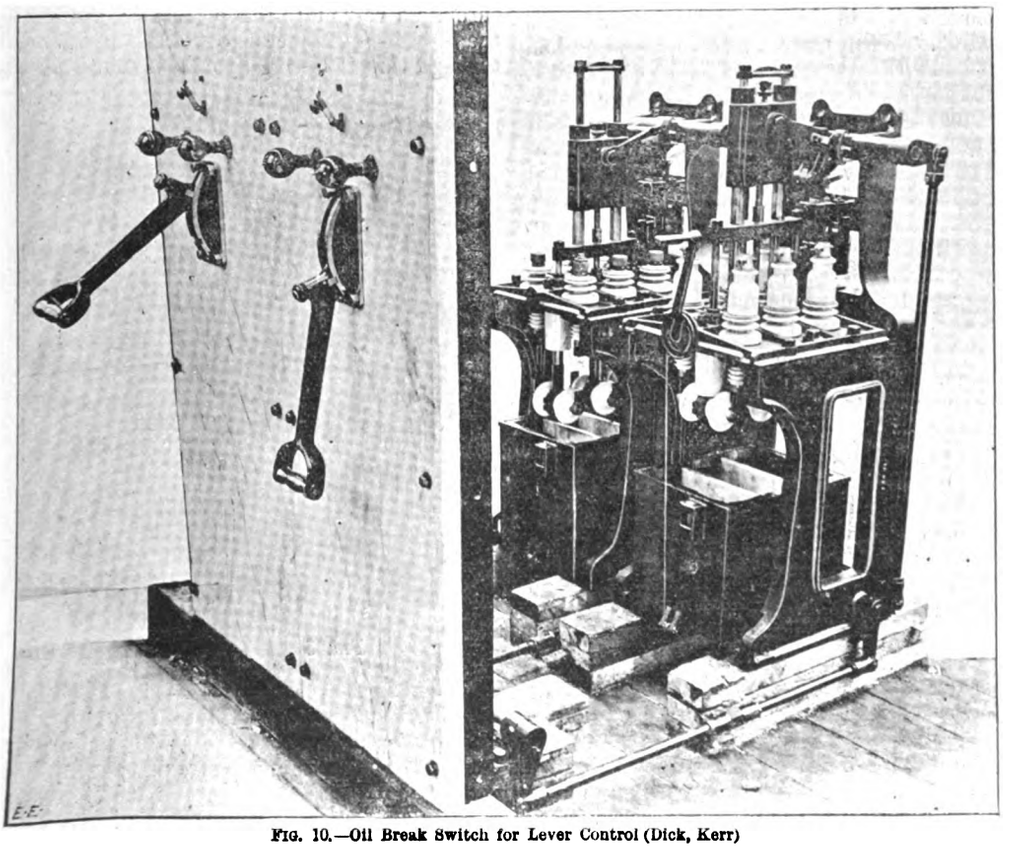

FIG. 10.—Oil Break Switch for Lever Control (Dick, Kerr)

Digitized by Google

is a small one, hence it is often overlooked; but as it is obvious that in practically every case purification of waste oil must have an appreciable bearing upon economy, it follows that suitable apparatus for effecting it should always be provided and considered as of equal importance in its own sphere to any other saving device.

The impurities found in waste oil are often very numerous and different in their nature. They may be roughly divided into two heads—chemical and mechanical, and according to which class they belong, so the means for eradicating them will differ. Chemical impurities must be treated chemically, while those of the second class may in all cases be removed by filtration in one or more of its several forms. Oil that is exposed for a long period to the heat of an enclosed engine crank chamber will often become charged with fatty acids consequent upon decomposition, and, needless to say, their presence is always highly undesirable, and may even become dangerous. Filtration will not remove them, but treatment with an alkaline solution has been found very effective. The extraction of mechanical impurities as performed in filters may be either by the action of settling, with or without agitation; siphoning, in conjunction with subsequent settling; percolation, or various combinations of the three. The former—viz., settling without agitation—is the simplest, as the apparatus consists only of a large and deep tank, to the bottom of which the impurities sink by their own weight; but purification by this means, although effective, is a somewhat lengthy process, and one that may be easily upset by careless handling of the apparatus in adding or withdrawing oil.

Fig. 1 represents in diagram a filter of this class, adapted for greater speed and convenience of working by the addition of the agitation principle, combined with a heating arrangement. It will be noticed here that after passing through the first strainer that removes all large impurities the oil sinks down a pipe, the end of which is immersed in water kept warm by the steam heating device placed beneath in a separate chamber. Many of the larger impurities immediately sink to the bottom, others are thrown out by agitation or the rapid rise of the oil through the water (represented in all the figures by broken lines), and the whole of the time the oil is in this compartment settling is gradually proceeding. When the oil (shown in unbroken lines) reaches the top of the centre pipe, it wells over, falling into the funnel-shaped receptacle in the lower compartment. Its head—exaggerated in the figure—forces it down the pipe, and it emerges in drops at the bottom, passing through cold water and a perforated plate that serves to lengthen its path to the body of pure oil floating on the water. The remaining impurities now settle out, and the oil at the surface is clean and ready for drawing off by aid of the top cock, the bottom one being used for withdrawing the water and for cleansing purposes.

Fig. 2 shows a thoroughly good modern filter, in which the percolating principle is used in addition to that of settling by agitation. The dirty oil is poured into the upper tray, and, passing through the filtering material, in this case cotton waste enclosed in a metal strainer, drips into the receptacle surrounding the perforated head of the down pipe. As in Fig. 1, it emerges from the bottom and is distributed through the water (heated by a steam coil at the base), shaking out the remaining impurities, and rising to the top, where it is drawn off. Many filtering agents have been tried in oil purifiers, blotting paper, meat rags, felt, and other like substances; but waste seems to be most generally used, as for a given cleaning power it allows of the greatest speed of operation. Blotting paper is a thoroughly good material from the filtering point of view, but it gets very rotten, and is, on the whole, more expensive than waste, and needs more careful packing.

The filter shown in Fig. 3 is similar to Fig. 2 in that percolation and settling with agitation are both used and accelerated by means of heat, but the processes are reversed, the former coming after the latter. Such a filter would effect the desired end of purification very well, but its action would be slower than that of Fig. 2, since the latter provides a much greater weight of oil on the filtering substance than is represented by the comparatively small quantity contained in the down pipe of Fig. 3. Unless this pipe is always kept more or less full, according to the quantity of pure oil in the upper chamber, the filter obviously will not work. In this latter respect the filter shown in Fig. 4 is an improvement, as there is always a greater store of comparatively dirty oil forcing its way through the filtering pad, situated as shown on the left-hand side of the inner vessel. The two processes of agitation and percolation are repeated in the same order as in Fig. 3, and a disc is provided at the foot of the pipe to lengthen the path of the oil through the water, which is not heated. The small pipe on the left-hand side allows air to escape from the inner chamber as the oil

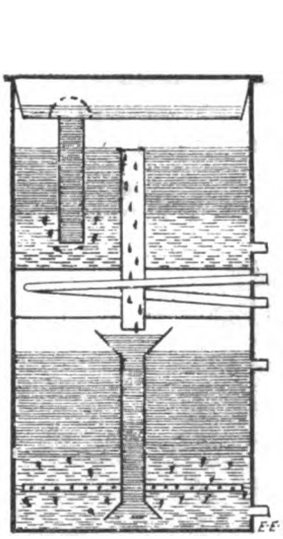

FIG. 1.

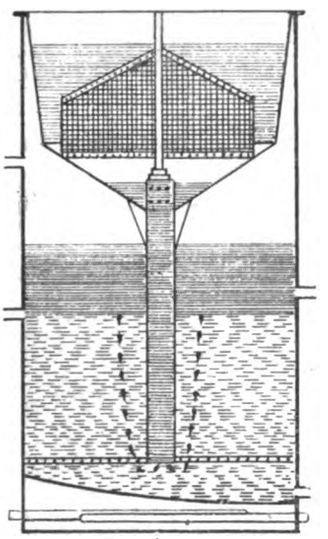

FIG. 2.

rises in it, and those on the right communicate with the clean oil and draining cocks respectively.

The remaining four figures show modern methods of oil purification that dispense altogether with the agitation principle, adhering only to filtration pure and simple and the ordinary process of settling. Fig. 5 shows some novel and ingenious points. The dirty oil is poured into the funnel and fills the outer chamber, passing from thence through a valve into the bottom of the container holding the filtering substance. By virtue of the head it now rises through this, following a tortuous course between the plates,

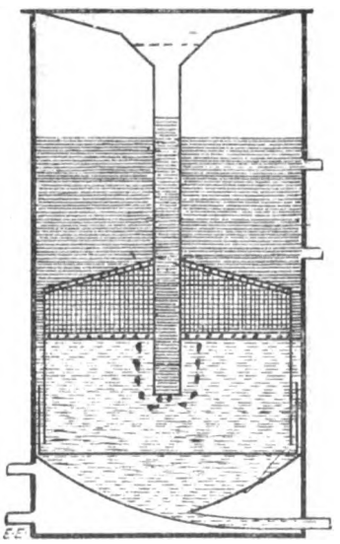

FIG. 3.

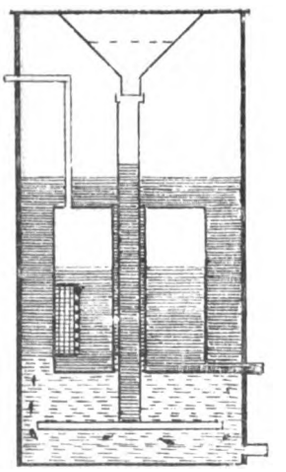

FIG. 4.

so placed as to secure a long path. It rises from the top of the filtering bucket and flows into the inner vessel, from which it is drawn as wanted through the pipe on the right-hand side. The chief novelty of the apparatus lies in the automatic valve, into the case of which the filter bucket is screwed by aid of the handle shown. In the absence of the bucket the valve is kept closed by the spring at the bottom, and hence the former may be taken out for cleaning or repair without emptying the oil from either the inner or outer containers. When the bucket is replaced the act of screwing it down opens the valve without allowing the two oils to mix, and permits the filtering process to go on as before.

Digitized by Google

Fig. 6 shows a three-stage filtration method, combined with settling processes in the first and second stages. The top chamber containing the first filter is removable, so that water and large refuse may be cleaned out frequently. The course of the oil is through the holes in the upper part of the first cylinder, and from thence through both filters to the large settling chamber, where most of the impurities deposit out. It then rises through the bottom of the third cylinder into the pure oil vessel, which is fitted with a cock. As the first two filters are only meant to deal with the larger impurities they are lightly packed and should be frequently cleansed, but the last stage requires better and

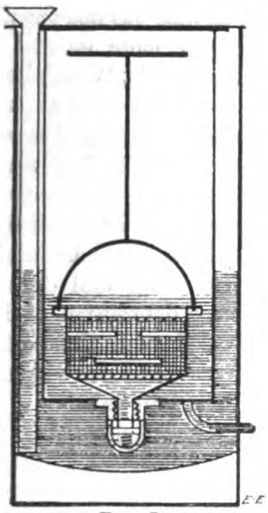

FIG. 5.

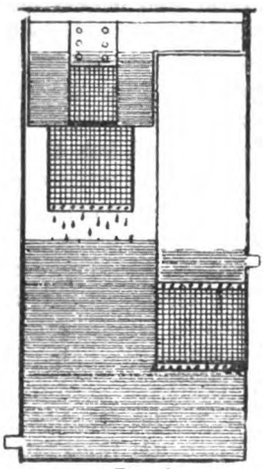

FIG. 6.

tighter packing, and in view of the settling action that takes place before it is reached, less cleaning.

Fig. 7 shows another three-stage filter, of different construction but based on the same idea of settling processes in the first and second stages. It is, however, primarily different, in that siphoning is introduced prior to the first filtering, replacing the perforated cylinder arrangement. On emerging from the bottom of this stage, the oil passes through outlet tubes and falls into the second compartment, where it settles, and rises over the top of the second filter, pursuing its course straight through the third, and arriving at the bottom receiver in a purified state. The filtration

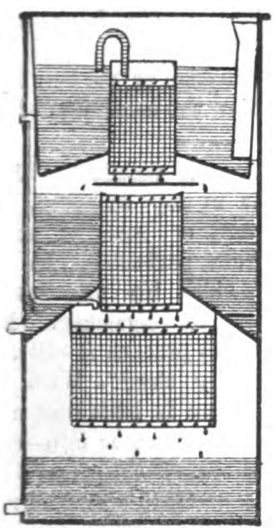

FIG. 7.

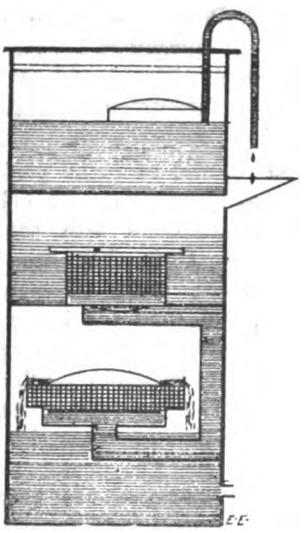

FIG. 8.

by this method is most complete and the apparatus will deal with the dirtiest of oil.

Fig. 8 represents a well-known and efficient filter, in which the first or settling stage is followed by a double percolation process. The floating siphon, shown in the upper compartment, is a good feature, as by this means, despite the level of the oil, only that on the very surface is passed to the filtering pads. The oil enters on the periphery of that in the first chamber, and, passing through, emerges into a channel that conducts it to the underneath side of the second pad, from the top of which it flows over to the lower or pure-oil chamber.

Other methods of waste oil purification are based on capillary and centrifugal actions, the former consisting of arrangements of siphoning wicks that naturally will not allow impurities to pass. In this respect they are very effective, but by far too slow for the average works requirements. The centrifugal method is good in that it gets rid of the dirt quickly and thoroughly, but it takes some power, and is rather costly when used on a small scale. On the whole there is nothing to beat a good filter built on scientific and common-sense lines. The material through which the oil percolates should be cheap, and so placed as to render renewal both easy and quick, and the whole apparatus should come to pieces so that it may be inspected and cleaned with facility. This type of filter should be so arranged as to make the later stages independent within a reasonable amount of the dirty oil fed into the first strainer—that is, they should always hold a good reserve—and it is important that the process of filtration should not be forced by continual filling up and working at full capacity. In the same way, the settling type of filter works best at light load, and will only give poor results when supplied with too large a quantity at once.

## GLASGOW LOCAL SECTION.

The Glasgow Local Section of the Institution is in full force this winter with a number of important papers, some of them of more than local interest. The paper read at the December meeting by Dr. Henderson, of the University of Glasgow, on "Armature Reaction in Alternators," was one of these. The investigations described in the paper had been carried out in the James Watt laboratory of the University of Glasgow by the author and Mr. J. S. Nicholson. The paper was divided up into a number of different headings, each of which was largely illustrated by mathematical formulæ and curves. First of all the theoretical armature reactions were considered, and then the author went on to deal with the demagnetising and cross magnetising components of the armature reaction. The experimental research was carried out on an armature of the Electrical Company's standard make, having rotating field poles, and a periodicity of 50 cycles per second when run at a speed of 750 revolutions per minute. The normal voltage was 200, and the current at full load was 87 amperes per phase. Summarising the results at the end of the paper, Dr. Henderson said: "The theoretical load curves of the three-phase generator which have been calculated in the paper by a method like Blondel's, employing a Fourier analysis of the armature M.M.F.'s, do not agree with the experimental load curves within the limits of the experimental errors, but deviate from them in certain well-defined respects. The limits of experimental error are a small fraction of the maximum deviation, and the deviations themselves are so small as to be negligible in matters of design."

In the discussion which followed, Prof. BAILY was the principal speaker. He said that the higher the harmonic the more effective would the amortisseur coils be, because the higher the periodicity the greater the inductive effect, and the greater the effect on the field magnets in obliterating the variation of current. It would be very interesting to know if the coils gave large indications of reversing currents or obliterating currents.

Mr. H. A. MAVOR said he would like to know if Dr. Henderson's experiments could be carried out on a larger machine. The cross magnetising effects which were negligible on small machines would be much greater on machines with three or four times the radial depth.

Mr. HIRD wished to know how the ordinates of the square curve in one of the figures had been arrived at.

Dr. HENDERSON, in reply, said it would be interesting to experiment further along the lines suggested by Mr. Mavor. The results, however, would depend on the ratio of the pole breadth to the pole pitch. His experiments had been begun with a view to finding out how far those M.M.F.'s in the analysis of the total armature M.M.F., which theory indicated should be stationary over the poles, could account for the effects obtained in practice, and the results had been most satisfactory.

## TELEPHONY AT PARIS.

It has been suggested that the two reports of Mr. Herbert Laws Webb to the Association of Telephone Subscribers of Paris provide food for thought and comment. They do. The moral underlying the text of these reports is just the same as that underlying the "passing of our fleet" or the "regunning our army." Progress leads to what is termed antiquation or obsolescence. Time acts very much the same on humans; and we are often taunted with being antiquated old fogeys, who ought long ago to have given up all interference with the world's work and left it to younger men with whom time has not yet played havoc, and who possess more energy, more go, and claim more up-to-date knowledge. Practically Mr. Webb's lesson is a variant upon the theme that you cannot look as well in old clothes as your neighbour does in a brand-new suit. The conclusions at which he arrives are obvious, and will not be disputed, but Mr. Webb does not and cannot, nor can anyone, show us how to overcome the initial difficulty, which is to provide apparatus which will never be improved upon, nor become old. What he does, and does well, is to give an exceedingly interesting description of how a telephone service should be installed with the best that exists now to be efficient. The requisites to which each subscriber is entitled are tabulated as follows:

1. Uniformly good transmission, comprising
   - (*a*) Good hearing.
   - (*b*) Good talking.
   - (*c*) A line with no extraneous noises, what telephonists term a "silent" line.
2. A uniformly prompt answer from the exchange.
3. A uniformly courteous answer from the exchange.
4. A uniformly prompt and accurate connection with the number desired; or, failing that,
5. A uniformly polite and businesslike report of the reason why the desired number cannot be obtained.
6. No interruption of the conversation with his correspondent by the operators or by third parties.
7. Prompt attention of the operator in case of difficulties.
8. A uniformly prompt disconnection of the two lines connected immediately after the conclusion of the conversation.

Of course, as great perfection as is possible in these points is necessary for efficiency in any exchange, and the report deals with the reasons, or some of them, why in Paris they are far from perfection. In the first place, every subscriber provides his own instrument, and even a primary battery for signalling. Mr. Webb states that "the origin of this practice is obscure, but its unfortunate results are very clear." With the latter phrase we quite agree, but there is little obscurity in the origin of this practice. We cannot enter into—and we have no right to do so—questions of French politics, but the origin of the obnoxious practice, also the real causes of staff inefficiency, must be sought, like so many things, in the realm of politics. Mr. Webb admits that he has had no experience from the inside. We understand "the president of the association has made formal application to the administration for Mr. Webb to be allowed to make an official inspection of the Paris telephone exchanges with a view to reporting on their condition and on the apparatus and methods employed." As regards the reports we are referring to, he has relied upon his general knowledge of the Paris telephone service "acquired from published descriptions and from observations made during various visits to Paris in the past few

Digitized by Google

years, and not upon a detailed inspection of the system, such as would be necessary for a statement in detail of the technical and financial considerations involved in a reorganisation of the system." This admission fixes the position of the reports, and we trust it will be thought complimentary to them if we object to accepting them as having any particular value in Paris criticism, but as undoubtedly having a high value as general guides, and as indicating precisely the lines upon which a rigid specification should be constructed so as to obtain not only an efficient system at Paris but anywhere. Mr. Webb practically says this is the present condition of our knowledge; this is what the subscriber wants; and this is how, in his opinion, it should be installed to obtain efficiency and economy. His discussion of details is necessarily general, and, as we say, does not specially apply to Paris, but holds good for any place. His conclusion is to "reconstruct with modern central offices and subscribers' station apparatus"; in that of the three periods into which he classifies telephone development, Paris still retains most apparatus that belongs to the first, little that belongs to the second, and none that belongs to the third. Drastic remedies involving reconstruction require a very careful consideration of all conditions. Your capital expenditure is increased to the cost of the new construction in addition to the remaining capital of the old, and the question depends upon the total of the new revenue. If that will carry the capital, the outlook is favourable; if not, you must have a loss. Mr. Webb thinks that the telephone business in Paris would enormously increase, and if his figures are even approximately accurate, his suggestion for complete reconstruction is amply warranted.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### THE METRIC FALLACY.

SIR,—Thanking you for having inserted my last letter, may I be allowed to briefly refer to your second article on "The Metric Fallacy," appearing in your issue of Dec. 23.

You allude to the rejection by the French of the 10-hour day. It would seem almost unnecessary to point out that the metric system of weights and measures, as advocated by the Decimal Association, has nothing whatever to do with the division of the circle. In fact, there exists a very common confusion of ideas between the proposal to adopt the metric system of weights and measures and a supposed desire to decimalise everything. Another mistaken idea is that by the adoption of the metric system vulgar fractions would be abolished. Just as now with our present system we often find it convenient to use decimals, so with the adoption of the metric system we should often find it convenient to use vulgar fractions.

It is quite true that a gallon of water weighs 10lb., and we have in that fact a connection between our measures of capacity and weight, but it is far from an ideal one. If a cubic inch of water weighed an ounce or some recognised unit of weight we should be much happier. Compare the connection with that in the metric system, a cubic centimetre of water weighing a gramme, by which the weight of any given volume of water may be estimated at sight.

With regard to your allusion to British consuls, it is not my business to defend their character as men of capacity and as having some regard to British interests, but I should like to refer to the reply sent by our diplomatic representatives in answer to a circular issued by Lord Salisbury in 1899, asking for information, amongst other things, as to the effect the adoption of the metric system had had upon the commerce of the nations using it. The general tenour of the replies was, that the adoption of the metric system had facilitated internal trade, that it was also beneficial to trade with other countries using the metric system, and that in no country was there any desire to revert to the old weights and measures.

But after all, sir, the question centres round the retention of our present units, which, after long use and familiarity, we are, naturally enough, loth to dismiss.

We find our inch very serviceable. The table connecting it with the higher measures is admittedly bad, but taken by itself it is a good unit (so is the yard, so is the pound), but the chief disadvantage of our present lack of system is that the inch and the pound are not inter-related, as I have shown above, by any simple and workable connection; and it seems impossible by any reform of our existing system to bring about such a connection.

We may regard a system of weights and measures as part—and a very important part—of the machinery of our national trade, and, like other machinery, we require it to be up to date. At present we have no system, but a "farrago" of weights and measures, as Lord Kelvin has called them.—Yours, etc.,

E. JOHNSON,
Secretary, the Decimal Association.

---

SIR,—In your issue of Jan. 6 there appears a letter under the above heading from the secretary of the Decimal Association, which is very apt to mislead those who are not well posted up in the weights and measures question.

The writer states that "If the contentions of Sir Frederick Bramwell are carefully considered, it will be found that he was protesting, not against the metric system, but against the compulsory use of decimals to the exclusion of vulgar fractions." If the writer, in using the words "metric system" in this paragraph, refers to the principle whereby length, volume, and weight are co-related, Sir Frederick was not against the metric system, but if he leaves the readers of your paper to understand—as they undoubtedly will understand—that the words "metric system" used in the aforesaid paragraph refer to the system based on the metre, then Sir Frederick was one of the strongest opponents, and for the reason that the use of the metre and its derivatives compels the use of decimals to the total exclusion of vulgar fractions, except the very simplest.

The argument about the list of 50 "customary" weights and measures still used in this country is an argument that has been trotted out for the last 50 years, and is still used as being a truthful statement, notwithstanding the very successful efforts which have been made during the last 10 years, particularly by the Standards Department of the Board of Trade, and the various weights and measures authorities throughout the kingdom, to replace them with imperial units.

There is also a statement that "even America is no longer with us," because, forsooth, they express their yard in terms of the metre and their pound in terms of the gramme, and they have a different gallon, whilst they use a ton of 2,000lb. The contention is most ridiculous. Let me give the official figures of the English Board of Trade and the United States Bureau of Standards, and then let your readers judge of how true is the statement that "America is no longer with us":

United Kingdom: The yard $= \frac{3600}{3937}$ metre. The pound = 453 59243 grammes.

United States: The yard $= \frac{3600}{3937}$ metre. The pound = 453·5924277 grammes.

It will be seen that the only difference is that English commonsense has stopped after dividing the already small weight of a gramme into 100,000 parts, but the United States Department has carried the fraction two points still farther; but even then it is not finality, and could be carried on much farther still.

To say that the United States is not with us on account of its having adopted a 2,000lb. ton is childish in the extreme. We might with just as much truth say that Liverpool corn merchants are not with us because they have adopted the sensible weight of 100lb. cental, instead of 112lb. hundredweight.

Respecting the volume measures of the United States,

Digitized by Google

the difference is accounted for by their still retaining our old Winchester wine gallon, which was replaced in this country by our present and more scientific gallon, and which is defined as "a vessel that will hold 10lb. weight of water."

If such puerilities are the best arguments (?) that can be used to support the metric system, then it is very evident that the organisation of the opposing forces has begun none too soon.—Yours, etc, GEO. MOORES.

## TURBINE NON-STOP RUNS.

SIR,—In your issue of Jan. 6, 1905, I notice under "Business Notes," p. 30, that you speak of a 600-h.p. Westinghouse steam-turbine having run for 3,962 hours—"a remarkable performance in the history of the steam-turbine," as you put it. You further speak of this performance as "the record run of the Westinghouse turbine." This may be the case for a Westinghouse machine, but both Messrs. Parsons and Messrs. Brown, Boveri, and Co., Limited, have machines which have been in continuous service for longer periods.

For your information I beg to enclose herewith copy of a telegram addressed to Messrs. Brown, Boveri, and Co. in connection with a 600-h.p. Brown-Boveri-Parsons steam-turbine which ran for *17,200 hours—i.e.*, more than four times as long as the Westinghouse machine—without absolutely any repairs or adjustments being necessary, and this machine is at the present day in successful continuous operation. I think that this constitutes a record for a prime mover of this output.—Yours, etc,

EXCELSIOR.

## SOME NOTES ON HIGH-SPEED FEED PUMPS AND THE REASONS OF THEIR INEFFICIENCY.*

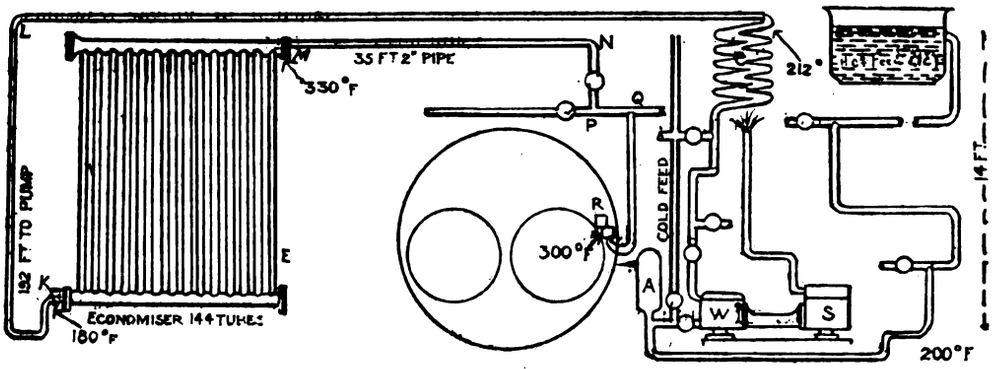
BY E. C. BARTON.

Most of us have, at some time or other, bestowed an infinity of pains on one thing and found out afterwards that it was not so important as it looked, and some other neglected matter grew to be such a source of trouble as to bring all our exertions to naught. Such thoughts were suggested to the author when studying the matter of steam pumps by a perusal of the troubles of an electrical engineer in England, who had charge of a large electric plant fitted with the very latest appliances, engines with a steam economy guaranteed down to three places of decimals, and mechanical stokers, superheaters, coal conveyors—in fact, everything needed to make a perfect plant, but which in the ordinary work suffered from big coal bills, owing to the losses in the "auxiliaries." When one reads that a Mr. Jeckell had found a pump using 1lb. of steam to feed 1lb. of water, it becomes interesting to find reasons. It appears that the pump was of the high-speed type, and was working slow, but even at ordinary speeds a delivery of 30lb. of water (per pound of steam used) was a record, while pumpmakers assert 35lb. to be attainable.

On investigating the matter the first difficulty to solve is, why is the water end of a steam-pump so much smaller than the steam end? A catalogue (Worthington's) was consulted, and gave the following ratios: 3, 4, 3, 2¼, 2·7, 2·5, 2·8, 3·5; another catalogue (Marsh's) gave 3, 3, 3, 2·75, 2·25, 2·5, 2·8; while another (Weir's) gave 1·9, 1·8, 1·8, 1·7, 1·8 as the ratio between the steam-cylinder area and the water-cylinder area. Thus the average ratios are 2·97 for Worthington, 2·72 for Marsh, and 1·8 for Weir, and from the mere sizes of the cylinders a Worthington should take 2·97lb. of steam to do the work which a Weir will do with 1·8lb. This statement may be made more accurate by substituting cubic feet for pounds, but it is substantially correct, because the period of rest at the end of each stroke, even in a duplex pump, is generally sufficient to bring the pressure in the cylinder up to full pressure, and any throttling of the steam in the steam stop valve is thus rendered insignificant as far as economy goes. The full-speed diagram of the steam end of a pump is generally a right-angled parallelogram with a small peak at the end of the stroke. At lower speeds, due to throttling the steam supply, the average pressure is lower, but the final peak is just the same at the end of the stroke, and that peak means that the cylinder takes a full supply of steam, at any speed, before exhausting, or nearly so.

Leaving the steam end losses and turning to those at the water end, the greatest source of inefficiency in a steam pump is discovered—*i.e.*, friction of packings. It is here that resides the difference in efficiency between a slow-moving 7½in. by 15in. Weir at 17 strokes per minute and a quick-speed duplex 2¾in. by 4in. Worthington working at 200 strokes each cylinder (equivalent to 400 strokes of one cylinder). At the above speeds both pumps are approximately of the same output—*i.e.*, 18,000lb. per hour—but the friction losses are in the quick-speed small pump more than double those incurred in running the large slow-speed pump. The reason lies in the fact that the work expended in friction is in each case proportional to the surface swept by the piston, whereas the discharge of water is proportional to the volume swept by the piston.

The author, having under consideration the replacement of an existing Worthington pump by a Weir, had occasion to make the following calculations in comparing the relative advantages of the two types of pump. The existing arrangements of the Worthington pump installation are shown in the accompanying diagram, wherein T is the tank,



K is the suction pipe, P is the water cylinder, S is the steam cylinder of pump, A is the air vessel, C is a heating coil, E is a Green's economiser, and B is one of a battery of Lancashire boilers. The essential data concerning the Worthington pump, the proposed Weir pump, and the pipe system are given below: Worthington pump—steam cylinder, 4½ by 4; water cylinder, 2¾ by 4; Weir pump—steam cylinder, 10 by 15; water cylinder, 7½ by 15; length of suction pipe, 70ft.; length of delivery pipe from pump through auxiliary heater to economiser, 195ft.; length of delivery pipe from economiser to boiler, 35ft.; internal diameter of pipe, 2in. To the friction losses caused by the movements of the piston or plunger must be added the losses arising from the friction in the gland stuffing boxes, which, although usually small compared with the former, may by the zeal of the attendant be indefinitely increased. These losses are, in the case of the quick-speed pump, about 10 times larger than with the slow-moving pump.

The next serious loss arises from slip, which is partly due to leakage past the piston, but is also due to leakage through the valves. Slip is not a factor in determining cylinder ratios, but it is a serious factor in lowering efficiency at slow speeds. In some local tests I have found it amount to 10 per cent. on the full speed output, but

* Paper read before Queensland Institute.

Digitized by Google

with fresh packing and true cylinders it should not exceed 3 or 4 per cent. Unfortunately, slip remains nearly constant, while the output varies with the speed, and it is possible to run a pump so slowly that the whole of the displacement of the piston just equals the slip, and the delivery of water is nil. The slip may then be said to be 100 per cent. One of the most interesting pump questions is that relating to the flow of the water in the suction and in the delivery pipes, as the inertia of the water and the friction are appreciable factors in the working of pumps, especially of the quick-speed type, firstly, because they increase the amount of work required of the pump, and, secondly, because they cause a difficulty in dealing with hot feed water or long suction pipes.

Following up the case of the local pump above mentioned, it can easily be shown that the full speed of 200 strokes per minute per cylinder involves stopping and starting the column of water (continued in the pipes) 400 times per minute. In proof of this may be mentioned that this pump will not work if the check valve, V, at the economiser is removed. In the case under observation the column is 200ft. long and 2in. in diameter. It must travel the distance of 7½in. every stroke, and, therefore (if starting from rest), it must attain a velocity of 15in. per stroke—*i.e.*, the average speed will be 4ft. per second, but the velocity attained will be 8ft. per second by the end of the stroke, so that the acceleration of 8ft. per second must be given to this column of water in $\frac{1}{400}$ minute (·15 second). This means 60lb. per square inch added on to the boiler pressure. The calculations relating to the above are as follows: the weight of water in the pipes = W.

$$W = \frac{200 \times 2 \times 2 \times 3{\cdot}14 \times 63}{12 \times 12 \times 4} = 300\text{lb.}$$

The quantity of water moved by the piston at each stroke must travel in the pipe a distance which is as much greater than the length of the stroke as the area of the piston is greater than the area of the pipe, hence movement of water in pipe per stroke:

$$\frac{4 \times 2{\cdot}75 \times 2{\cdot}75}{2 \times 2} = 7\ 3\text{in.}$$

If the pump is working at full speed, the water in the pipe must travel this distance in $\frac{1}{400}$ minute—*i.e.*, its average velocity must be 2,920in. per minute, or about 48in. per second (4ft. per second). This column never stops, but probably its velocity varies from 2ft. to 5ft., and therefore an acceleration of 3ft. per second must be imparted to it 400 times per minute—*i.e.*, in ·15 second. This is equivalent to producing an acceleration of 20ft. per second in one second. The force required to impart this acceleration to 300lb. of water is

$$\frac{20 \times 003}{32}$$

= 180 (32 = gravity acceleration). This force requires pressure of 60lb. per square inch added to the boiler pressure of 160lb. The friction losses in the pipe are small in comparison; they amount to about 2lb. per square inch.

In the delivery pipe the inertia causes increased work to the pump, but in the suction pipe it causes further troubles, especially with hot feed or long lifts, owing to the inability of the column in the suction pipe to follow the pump piston. Even with an elevated supply tank and cold feed water this trouble may arise, but with hot feed the trouble is very serious, owing to the vapour tension. In the case under the author's observation the feed water comes to the pump at about 200deg., which corresponds to 12lb. absolute, and leaves only 2¾lb. surplus of atmospheric pressure to assist the column. The supply has 12ft. head, but even then it was found impossible to maintain a steady feed without an air vessel on the suction side. An air vessel was tried on the delivery side, but the results were alarming—the pump ran away violently. Even with cold feed it is well to have an air vessel on the suction side, or an open standpipe if the supply tank is elevated.

Pump troubles are so serious, and pump efficiency is so low, that any study bestowed upon them is well invested, but the subject is of too wide a scope for a single paper, and hence the crankshaft pump and the flywheel pump have been ignored, as also the permissible lift of water-valves, piston packings for hot feed water, the author's attention being confined to seeking an explanation of the inefficiency of the small high-speed pump as compared with the large slow-moving feed pump.

## TRADE NOTICES AND NOVELTIES.

### Small Three-Phase Motors.

From the Lahmeyer Electrical Company, Limited, 109-111, New Oxford-street, London, W.C., we have received an illustrated description of their small three-phase motors—types D and Ds. These motors represent a recent departure, and are manufactured in eight standard sizes. The smaller sizes up to 1 h.p. are provided with squirrel-cage rotors, while the larger machines can be supplied with or without slip-rings, as may be required. The motors have end shield bearings and take up very little space. The slip-rings allow of inserting a resistance in the rotor circuit. They are mostly used if it is deemed inadvisable to start from the high-tension stator side or if a high starting torque without an excessive starting current is required. The slip-ring (Ds type) motors can be arranged to give 2 to 2½ times the normal starting torque with a starting current corresponding to about 2½ times the normal full-load current. On the other hand, the squirrel-cage (D type) rotor machines, without slip-rings, will give only a comparatively small starting torque. Their advantage lies in the fact that, with the exception of lubrication, they do not require any attention whatsoever. All the motors are fitted with improved ball bearings, manufactured by the Deutschen Waffen und Munitionsfabriken Berlin, whose agents in this country are Messrs. L. Loewe and Co., London. By means of these bearings the oil consumption and frictional losses are greatly reduced. It will be remembered that we described the principal features of their construction in our issue for Dec. 9 last.

### Lifts and Hoists.

Messrs. Archibald Smith and Stevens, of the Janus Works, Battersea, have forwarded us an excellently-illustrated and up-to-date brochure describing their specialities, which consist of electric and hydraulic lifts and hoists. The technical section discusses the merits of the various types, and gives comparative tables of working costs for electric and hydraulic lifts, which, we may remark incidentally, show a big margin in favour of the former. The new machines devised by this firm comprise direct-coupled, self-starting, and reversing lifts for operation by single-phase alternating current. In a recent test this lift performed 18 complete round trips per unit, raising 10cwt. to an altitude of 45ft. Other features are a single push-button switch, in which many of the usual adjuncts have been dispensed with, and an automatic parcels lift, which can be controlled entirely from one floor. The pamphlet testifies to the amount of attention Messrs. Archibald Smith and Stevens have devoted to improving this class of machinery.

### The Diesel Engine.

Some useful information relating to the Diesel oil-engine is contained in a new illustrated pamphlet issued by the Diesel Engine Company, Limited, 179, Queen Victoria-street, London, E.C. We note that the total horse-power of these engines installed is increasing very rapidly; further, that a unit of 500 b.h.p., coupled direct to a dynamo, will be exhibited at Liège this year. This is claimed to be by far the largest oil-engine ever turned out, but the makers evidently do not intend to rest, having, they tell us, engines respectively of 750 b.h.p. and 1,000 b.h.p. now under construction. As regards the special claims put forward for the Diesel engine, more particularly on the score of economy, we may leave the pamphlet in question to speak for itself.

### Litholite Bushes and Handles.

Messrs. Hunt and Hess, Litholite Works, The Grove, Hackney, London, N.E., have sent us copies of some new sheets showing standard litholite bushes and handles, together with their current price-lists. On the new sheets all the old patterns of the articles in question which have proved useful in the past will be found, besides a large number of new ones. The drawings are to full size scale, with the principal dimensions clearly indicated. We note that Messrs. Hunt and Hess now supply any suitable Whitworth screw with their handles at a uniform charge; also that they supply litholite in various qualities according to requirements. It is claimed that this material affords perfect insulation, and is unaffected by damp.

### Underfeed Stokers.

The various types of underfeed stokers manufactured for internally-fired and all kinds of water-tube boilers by the Underfeed Stoker Company, Limited, Coventry House, South-place, Finsbury, London, E.C., are fully described in a new pamphlet issued by this firm. The illustrations given enable their action to be clearly understood. Over 4,000 of the machines are now at work in various parts of the world we are told. Apart from the descriptive matter, the reports of tests showing important economies, included at the end, should make this pamphlet very useful for reference purposes.

### High-Speed Electric Drilling Machines.

Through the courtesy of Kramos Limited, Lockabrook Engineering Works, Bath, we are enabled to illustrate here-

Digitized by Google

with two of the exceedingly handy types of electrical drilling machines manufactured by them. The "Midget" drill (Fig. 1) has a capacity up to ⅝in. holes, and weighs only 15lb. complete. The light weight of this tool is due to its being encased in a solid aluminium casting, while the magnets are of special high-permeability steel, and contain just sufficient metal to ensure the magnetic field required. The armature is also of special type, being longer in proportion to its diameter than is usual. The gearing is machine cut out of solid steel blanks. The drill spindle runs in a long bearing, and is provided with ball thrust plates. Special attention has been given to the brush gear in order to eliminate the possibility of trouble through vibration. The handles for holding the drill are of aluminium, being cast on to the casing. It is noteworthy, also, that the cover has been formed to serve as a breast-plate. An extra strong switch of quick make-and-break pattern is fitted to the machine. It is contained inside the aluminium casing, being actuated by means of a push-button which protudes through the casing, as shown in the illustration. This particular type of machine should prove most useful in repair workshops where a large number of small holes have to be drilled. Fig. 2 illustrates a Kramos "Runthru" drill. This tool is likewise encased in a solid aluminium casting, the inside of which is machined at one operation on a special lathe, with milling attachment, designed by the firm for the purpose. The magnets are of the Manchester type. Two magnet coils are provided, which are compound wound to give a speed variation of nearly 50 per cent. between no load and full load. This is a particular advantage when drilling holes of smaller diameter than 1in., as the speed increases automatically. Two reduction gears are provided. The pinion on the armature has a diameter of 1¼in., and the intermediate gear is of one piece of steel turned out of the solid, and, like the rest of the wheels, machine cut. Much care has been taken to obtain proper bearing and guidance of the drill spindle. A ball thrust bearing is provided. The brush gear and terminal plate are of special design, and all wires and connections inside the drill are embedded in insulated slots. The "Runthru" is capable of developing an output of 1 h.p., and will drill holes up to 1⅛in. diameter, the weight of the machine complete being 60lb. Another important feature of this drill is its small breadth, by

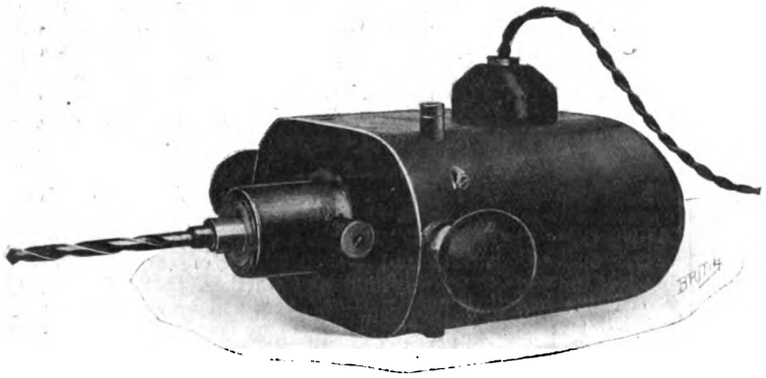


Fig. 1.—The "Midget" Drill.

Fig. 2.—The "Runthru" Drill.

virtue of which it may be used to drill holes in awkward places, the distance between the centre of the drill and outside of casing being only 2½in. With it the firm supply a starter of their original design, containing one Kramos patent resistance piece, a quick-acting switch, and an ammeter. The latter instrument is introduced so as to allow the drill to be run at its full output, and at the same time to prevent overloading. In other words, it enables the feeding pressure to be correctly adjusted when drilling. Every part of the machine is designed to withstand the maximum amount of rough usage to which such apparatus is commonly subjected. We understand that the firm are supplying the Admiralty with a specially designed magnetic brace for use with "Runthru" drills. These drills can be supplied for standard voltages up to 250 volts, direct current. Other interesting types are described and illustrated in the latest list of high-speed drilling machines issued by Kramos, Limited. They include the "Slick" drill, fitted with tapping device, and the "Dandy" drilling machine designed for operating drill heads by means of flexible or telescopic shafts, being particularly suitable for use in shipbuilding yards, railway or other large engineering works. Several magnetic braces designed for special work are also shown in combination with different drills. It remains to add that by specialising the particular class of apparatus under notice, Kramos, Limited, have rendered a considerable service to the British electrical industry. We trust an increasing measure of success will reward them for their enterprise.

## Catalogues, Calendars, etc., Received.

Calvert's Almanac, 1905. (John Heywood, Manchester.)—The thirty-second issue of this useful almanac and workshop companion teems as usual with industrial and interesting information for those connected with mechanical, electrical, engineering, building, and constructive trades.

Nalder Bros. and Thompson, Limited, 34, Queen-street, E.C., makers of N.C.S. measuring instruments.—Calendar and a descriptive card illustrating a new motor gauge which the firm have recently placed upon the market.

G. Clark and Sons, Limited, engineers, brass and iron-founders, Shipley, Yorks.

St. Helens Cable Company, Limited.—This company are circulating a number of picture postcards descriptive of their cables, tyres, wire, and rubber goods.

Power-Saving Pulley Company, 2, Weymouth-street, W., and Manchester and Birmingham.—A few remarks on the transmission of power by belting.

Jackson Bros., electrical engineers and contractors, Broadway and Herbert-street, Plaistow, London, E.

Robt. A. Thompson and Co., Limited, colonial publishers, 5, Tudor-street, E.C.

McClure and Whitfield, dynamo and motor manufacturers, Stockport.—A very serviceable pocket-book, containing, *inter alia*, a description and prices and particulars of the Mersey generator, multipolar type, from 40 kw. upwards, and Mersey ventilated enclosed, totally enclosed, and protected motors.

A. Ransome and Co., Limited, Newark-on-Trent, and 63, Queen Victoria-street, E.C., manufacturers of wood-working and sawmill machinery, cooperage machinery, and castings.

Robert Boyle and Son, ventilating engineers, London and Glasgow.

## NEW COMPANIES REGISTERED.

**A. G. Mumford, Limited.**—Capital, £50,000. Object: to acquire and carry on the business of A. G. Mumford, in Essex, as marine and general engineers, boilermakers, makers of and dealers in machinery, motors, and apparatus for the production and utilisation of electric power for light and other purposes. Registered office: Culver-street, Colchester.

**Shanghai Electric Tramways, Limited.**—Capital, £10,000. Object: to acquire, equip, maintain, and work by electrical, steam, horse, or other power tramways, railways, boats, and other means of communication in Shanghai or elsewhere in Asia, and to carry on the business of electricians, generators, accumulators, and distributors of electrical energy for light, heat, motive power, or otherwise, etc.

### Liens Registered.

**Electric Supply Company of Victoria, Limited, Liverpool.**—Lien registered Dec. 30 for £225,900 5 per cent. debentures, part of £200,000; amount previously issued, £75,000; no trustees; charged on all the property, present and future, the undertaking, goodwill, business, and uncalled capital.

## STAND-BY CHARGES AND MOTOR LOAD DEVELOPMENT.

BY A. M. TAYLOR, MEMBER.

The following is a short abstract of a paper read on Dec. 14 before the Birmingham Local Section of the Institution of Electrical Engineers.

After discussing the relative costs of gas, oil, and electric motors, the author discusses the actual costs to the station of two representative classes of motor worked under present conditions. He then considers the question of developing the station load by offering exceptionally low rates for motors based on a restricted hours' clause, and investigates in some detail the extent to which such an offer could be carried. He gives a diagram (Fig. 1) which shows conclusively, by assuming almost extravagant proportions to the possible demand for power under such circumstances, that the bogey of "day fogs" is a risk that need not be

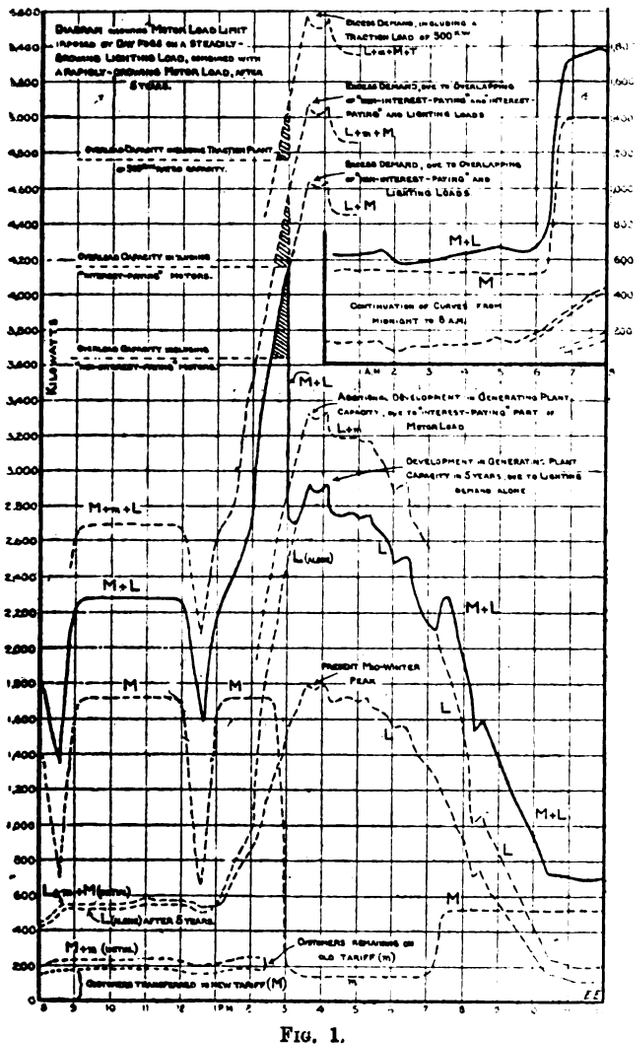

FIG. 1.

seriously considered in most towns. He analyses the charges at present made for lighting, and shows how much of this is often an interest charge on what he calls "unproductive capital," which he defines as "any capital expenditure, whether in plant or mains, which, if the station were started *de novo*, at present prices (and with present plant overload capacities), and put down with only sufficient margin to carry it safely over the next year or two, might be avoided." He gives a diagram to show how, under certain circumstances, stations having a large unproductive capital charge would be warranted in immediately reducing charges.

A diagram (Fig. 7) is given which is intended for central-station engineers, and is an attempt to represent the hourly rate of burning coal in terms of the kilowatts of output of that part of the load curve of the station which may be under consideration. The principle of the diagram is follows: Starting with direct-current kilowatts at 'bus bars, plot a curve connecting this with indicated horse-power, and a little below this curve plot another curve, nearly parallel to it, connecting kilowatts with electrical horse-power. The space enclosed between these two curves will then obviously represent the combined electrical and mechanical losses of the generator for different proportions of its load. Next, use the indicated horse-power scale as the scale of abscissæ, and for the scale of ordinates take pounds of steam delivered by the boiler per hour to the main steam range. Plot first a curve connecting steam consumed by the engine with indicated horse-power; then draw above this (in Fig. 7 it is shown at foot) a line representing excess steam necessary on account of steam feed pumps, then a line above this (also shown at foot in Fig. 7) representing condensation losses in steam-pipes to boiler and engine and in main steam range, then again a line above this representing steam consumed by the air and circulating pump engines. Lastly, take the scale of steam per hour and use it as a scale of abscissæ and set off a scale of pounds of coal per hour as ordinates, and draw a curve connecting these. To settle what scale to employ for the total pounds of coal per hour, we must first decide what evaporation to allow per pound of coal at full load of the boiler. The author has taken a figure of 7·68lb. for feed, as received from economiser, to pressure at, say, 160lb.; but this is a figure which each engineer must determine for himself, as it of course, depends on the coal used and the economiser and boiler efficiency. We now have a combination of three diagrams, and starting with any output in kilowatts, we can readily trace round through the three diagrams to the coal consumption per hour. We can also see the exact effect of "stand-by losses" in engines, dynamos, pipework, condensers, feed pumps, boilers, etc. The diagram is constructed for a station with three sets of 600 kw. each, two sets of 300 kw., and four groups of boilers, each generating steam for 600 kw. of plant. Suppose, now, that we had no battery in the station, and that, at a certain hour of the night, we had only a few amperes leaving the station—fortunately an unpractical condition—requiring, however, that at least one boiler be kept under full steam, and one dynamo maintaining 'bus-bar pressure, we find from the diagram that the stand-by losses are: indicated horse-power = 120; steam per hour = 6,000lb.; coal per hour = 900lb. This is for a boiler whose characteristic curve is given by the author, and an engine of 375 kw., triple expansion, by W. H. Allen and Co.

The author does not put forward any of the figures in Diagram 7 as final. He suggests that each station engineer may construct such diagrams to suit his own plant, and obtain from the engine, boiler, and pump makers curves for the apparatus they supply. If he then combines these, and finds that the pounds of coal per hour, taken for any convenient part of his load curve whatsoever, differ *radically* from that which he is really burning, he will be justified in commencing a search to know the reason why. It is here that the diagram will help him, for there are certain losses in it which must be substantially correct, or their cause would be easily detected. Again, there are others, such as steam-pipe radiation, which cannot be materially different from the plotted values; others, again, whose values, of themselves, are too insignificant to account for his discrepancies, and so on.

The author also gives two tables calculated from this diagram and from Figs. 2 and 4 of his paper, giving coal consumptions for the months of December and July, one of which—that for December—we reproduce. The curve in Fig. 2 of the paper off which this table is calculated is the same as that marked "present mid-winter peak" in Fig. 1, and we do not, therefore, reproduce Fig. 2. In an appendix the author considers more fully the principle on which he constructs Fig. 7 of his paper, and the way in which the diagram correctly represents the steam consumptions, etc., with a number of engines and boilers in parallel not all sharing the load equally.

At the meeting the author also exhibited a diagram (Fig. 7A), reproduced herewith, which is virtually the central part of his Fig. 7 considerably enlarged, which explains the elements of the diagram better than does the original Fig. 7, which is on a much smaller scale. This illustration Fig 7A differs from Fig. 7 in that some of the smaller losses, such as those due to the common steam main

Combined total = 1,273 tons per month. Units generated = 641,000 per month. Coal per unit = 4·45lb.

and branch to engines, to the boiler feed pump, and to the cooling tower motor fan, are plotted differently. The first two losses are plotted below the engine diagram, and the last is plotted above the dynamo diagram, in Fig. 7, which is the more correct, though perhaps not so suited for explanatory purposes as the present diagram. In Fig. 7 the second set is shown thrown in when the kilowatts supplied to feeders reaches 300 kw., indicated by the point B on the Fig. 7A. More correctly, it should be shown thrown in at the point A, as the first engine has to supply current for all the motors, etc., in the station before any is available for the feeders, and would be overloaded by some 20 per cent. The discrepancy so introduced does not invalidate the coal consumption readings materially, for the extra indicated horse-power to drive the dynamo which supplies current to the motors is taken account of; and the discrepancy is reduced with each succeeding engine thrown in. It will be noted that the various losses are duly added together, so that for zero output on the feeders 700lb. of coal are consumed per hour. This method of representing the combined losses of several engines and boilers, etc., running at varying proportions of their load, as shown in the present diagram, is of great practical service to station engineers.

[The author requests us to say that he has still a few copies of the paper left, which he will be pleased to send to any station engineers who are interested.—ED. *E E*]

Mr. Taylor, during the reading of his paper, gave the following additional information. He laid stress on the importance of the diversity factor, and said that he found it to be equivalent to the reciprocal of the load factor for the individual motor under consideration, illustrating his meaning by diagrams. He said that the system of charging a low rate to consumers who agreed to take no current for motive power between certain fixed hours during the winter months had proved a great success in Montreal. About 30 per cent. of the total horse-power connected is charged solely on this basis. The charges vary from £9. 12s. to £13 per horse-power annum. The system had been in operation four years, during which time it had not been found necessary to adopt precautions to ensure the switching off of the load at the stated times beyond those mentioned in the paper. They also sell power to small consumers for intermittent use at 1d. per horse-power hour, plus a fixed annual charge of £8 per horse-power intalled. The load factor at Montreal for the month of June was 75 per cent., and was practically the same throughout the year.

### DISCUSSION.

**Dr. W. E. Sumpner** congratulated Mr. Taylor on his paper, and referred to the importance of the subject. With reference to the figures quoted as to relative cost of gas, petroleum, and electric power, he said that these were subject to debate, but that they did not greatly affect the question, because electric motor development was delayed, not so much by the competition of good rival systems, as by the reluctance of owners of old and bad plant to change to a more efficient system. The amount of coal wasted in such old plants, say in the Birmingham district, was enormous, the total waste of coal throughout the country from this cause being probably greater than the amount exported. What they had to deal with was the consideration of how a well-arranged and well-designed station could, without loss, develop a motor load. Mr. Taylor had ably discussed in a scientific manner a method of determining the actual cost of the load at any time of the day, a method which should be extremely useful to engineers.

**Mr. J. E. Vaudrey** said that he had always been much interested in the supply of electric power, and he appreciated the amount of trouble and labour that the paper had evidently entailed. The proposal to cut off the peak of the load presented difficulties. It was not possible to conceive that the average works would be willing to shut down as had been proposed, especially as the amount of energy used forms only a small proportion of the total works cost. Even supposing the peak load to be cut off, he did not believe it possible to bring the charge below 1d. per unit. This is considered to be a bare price even for a traction load. He regarded the suggestion to instal accumulators on consumers' premises, especially on the small scale proposed, as impracticable. Had it been feasible, it would have been done long ago. With reference to the figures quoted by Mr. Taylor in connection with the Montreal supply scheme, he did not consider

Digitized by Google

£9. 12s. per horse-power annum as at all a cheap rate under the circumstances.

**Mr. J. A. Jeckell** (Coventry) questioned Mr. Taylor's assumption that 1 b.h.p. required one unit of electrical energy. At Coventry, where the average price obtained for motive power was 1·3d., the revenue obtained was only ½d. per brake horse-power hour. Lubrication in the case of a gas-engine is a big item, frequently 10s. per brake horse-power annum. In the case of electric motors it is small. As regards interest on capital, Mr. Taylor's figure of ·31d. per brake horse-power annum for a 17-h.p. motor working 2,500 hours gave £54. 17s. 11d. per year. He could buy such a motor for £57. He knew an instance in Coventry of a 15-h.p. gas-engine being replaced by a 15-h.p. motor. In the former case, allowing for interest and depreciation, and gas at 2s. 6d. per 1,000, the cost was ½d. per brake horse-power. The motor was hired from the supply company, and allowing for rent and energy at 1¾d. per unit, the actual cost per brake horse-power was ¾d. He did not see why the restricted hours' system should not be offered to consumers, but the special circumstances existing in each town would have to be considered. In Coventry it would not answer, as the chief trade is a season's trade. They never have the full motor load superimposed on the lighting load. Many motors were off at 5.30, and the top lighting load did not occur till 7.30. Wages and repairs should have been considered, as here the advantage lay with the electric motor. All things considered, the figures given by Mr. Taylor did not show electric driving in anything like so favourable a light as they should do.

**Mr. R. P. Wilson** (London) said that Mr. Taylor had shown that electricity could be profitably supplied to continuously-loaded motors at a price which would compete favourably with other prime movers, provided that this supply was not saddled with interest charges; and it therefore followed that within practical limits it could compete for intermittent loads. The actual load factor of such prime movers need not be considered. Such a load—*i.e.*, one that did not overlap lighting or necessitate capital expenditure—was nothing more than a by-product. If gas companies' by-products were saddled with the cost of production on the same lines, there would be no market for them. At Blackheath they were supplying electricity to several large firms at 2d. per unit, except between 5 and 10 p.m., when the price was 6d. He thought these prices financially disastrous as compared with 7d. or 8d. for two hours and 1½d. for 22 hours. At Dudley 6d. and 1½d. had been adopted. He found that manufacturers could almost always alter their hours to suit the price of power. If it was correct to say that the revenue from any class of consumer should be proportional to the plant they monopolise, then the time switch produced the desired result, as was shown by the following figures relating to Dudley: current consumed by shop, 25 per cent. of total; plant monopolised, 43·5 per cent.; revenue provided, 42·7 per cent.

**Mr. C. E. C. Shawfield** (Wolverhampton) could not agree with the pessimistic view that the author had taken as regards cost of electrical energy. He considered it commercially safe to offer a low price for motive power. At Wolverhampton the cost of production was much less than that mentioned. He did not agree with Mr. Vaudrey's statement that a tramway load was more profitable than a motor load, as he found the load factor was greater in the case of motors than for tramways. He criticised Mr. Taylor's statement that the load factor was the reciprocal of the diversity factor. At Wolverhampton the diversity factor was about 2, but the load factor was certainly not 50 per cent. The author's stand-by loss diagram should appeal to station engineers on account of its simplicity.

**Mr. Pringle** (Burton-on-Trent) referred to the question of fuel costs. In connection with this, he thought that allowance should be made for the fact that the boilers were not forced during the day to the extent they were at times of heavy load. They could therefore burn a cheaper grade fuel during the day. The total charge to consumer of ¾d. per unit, estimated by Mr. Taylor, was, he thought, a very safe value, which he considered might well be reduced. Mr. Pringle also wrote to suggest that the £270 additional capital outlay at generating station per kilowatt at motor was high. Many stations six to ten years old could to-day provide plant at station and allocate a fair proportion for mains at a much less figure than £270 per kilowatt.

**Mr. E. A. Chattock** (Birmingham) had been much interested in Mr. Taylor's paper. He would have liked a fuller explanation as to what was meant by continuous and intermittent loads for motors. At Bradford they had had a scale of 1d. for continuous and 2d. for intermittently loaded motors. By continuous they meant that the motor must be running all day, whether actually loaded or not. He had known people to run all day on no load in order to obtain the low rate. The average rate was 1¾d. Under these conditions they found that the motor load just paid for itself. He had suggested a sliding scale based on the amount of current consumed per horse-power per quarter. This system was tried for a short time, but consumers did not like it, and elected to go back to the old rate of charge. He felt sure that a charge of 1d. per unit without restrictions would not pay. It might at first, but after the load had developed the average price received per unit would fall to too low a value. Switching off consumers at certain hours might do in trades where firms can pick their men. He ventured to think that the good results obtained in Montreal are traceable to the fact that they have no trades unions as we have. The trades unions insist on the men working certain hours, which hours overlap the peak of load curve. Another point not yet referred to was that gas companies do not restrict the hours during which gas-engines may be run. Mr. Taylor referred to traction load in time of fog, saying that when the people are using the trams they could not be in the workshop. He would also point out that during fogs less trams were run, so that this class of load was then reduced. He did not agree with the scheme of putting in cells to tide over the peak load. He believed this had been tried by a London company, but had been discontinued, as after two years it was found that most of the cells were ruined. He suggested the hiring out of motors to consumers. Very good motor loads had been secured in this way. There were 600 to 700 motors on hire at Bradford.

**Mr. Morcom** considered that there was a strong case against shutting down at certain fixed hours. He had some figures relating to a factory in which the machinery was driven by electric motors. For every £1 of manufactured goods sold they consumed about one unit of electrical energy. As one of the chief things that has to be looked to is to get stuff out of hand quickly, there would have to be a proportionally heavy drop in cost per unit in order to make it worth the while of a manufacturer to shut down his works. His experience was that the number of units used in machine shops was being continually pushed up on account of the higher speeds of working now adopted.

**Mr. Fennell** (Wednesbury) said that the proposal to supply electricity to day users only at a low rate has been carried out for the past nine months (since commencement of supply) at Wednesbury, and that two-thirds of their motor load is already supplied on that system. To the long-hour user they offer as an alternative the maximum demand system. They had no difficulty in connection with time of cutting off. The electrically driven clock switch of the Reason Company was very satisfactory. It might also be made to act as a throw-over switch in connection with a two-rate meter, where the motor was required occasionally in the evening, a rate of 4d. or more being then charged. In Wednesbury there are a great many intermittent users who may be reached by the special day-load terms, such as corn merchants, pork butchers, breweries, laundries etc. There was little doubt in his mind that the actual field of the electric motor will be restricted to the short-hour and small-power consumer. In dealing with large manufacturers he had found a difficulty in honestly recommending them to take electricity even at 1d. per unit where it is proposed to run a 50-h.p. motor, say, 60 hours per week, at an average load of, say, 30 h.p. A suction producer plant will, in such a case, run with practically no attention, and cost of fuel at Wednesbury will not exceed ¼d. per unit.

**Mr. Holden** said that in most works there was a certain proportion of motors that ran intermittently, and it was always possible to arrange to cut these off at certain fixed hours during the day. He thought that though few manufacturers would turn out existing engines to instal motors, yet many would put in a motor when extending, and in this way drive a number of intermittently-loaded machines. He could name a number of cases where he thought the proposed low rate, with restrictions, would be acceptable. In some wood-working factories the machinery was only used three or four days per week; and in cases where power was required out of doors—hoisting, for instance—the machinery was only used during daylight hours.

**Mr. Arthur Wright**, in a written communication, referred to the success of the Reason Manufacturing Company's time switch at Brighton and other towns. At Brighton there were now 225 of these instruments in actual use. He did not agree with the author in reference to the diversity factor, as he considered that it would vary from a figure over 10 in the case of lift motors, down to 1 in the case of pump motors. This question of diversity factor could not be treated except by the method of probabilities. He considered 5 as a better average figure than 1½. In reference to the author's remarks respecting fog loads, it was an interesting fact that at Stepney, during the darkest fogs they had had this winter, the fog peak had never equalled the evening peak.

In a written communication, **Mr. Christie** (Brighton) said the system they used was most successful in every way. They fortunately had a large and steady demand for lighting in the evening, and the standing charges being met by the higher rate charged for this lighting, they could, at a profit to themselves, supply as much current at 1d. per unit as their day-load consumers liked to use, as they had simply to pay for coal, repairs, and attendance, which was easily covered by the sum charged. He did not know exactly what proportion of 1d. units were sold, but he estimated that it amounted to close upon three-quarters of a million units, which they would otherwise never have obtained, and which had a material effect in reducing the running costs.

**Mr. George Wilkinson**, of Harrogate (communicated), did not agree with the figures regarding gas consumption upon which Mr. Taylor had based his comparisons. Was Mr. Taylor aware of the wonderful advances made in the economy of working gas-engines? He referred to the suction gas plant, by means of which gas is produced in a very simple form of producer by the suction of the engine piston itself. Only recently he paid a visit to works where one of these plants was in operation. The engine was a 25 h.p., and the gas producer supplying its gas fuel was a very simple apparatus indeed, with no moving parts, the selling price of which was £90. This producer and engine was giving 1 b.h.p. per hour for fuel costing ⅛d. when using anthracite coal in the producer, and the engine had been running three months without any attention whatever. In his opinion the power companies have more to fear from competition introduced by the ordinary gas-engine and suction producer plant than from any other competitor, and it was difficult to see how, in face of such practical results as he had quoted, the power companies were going to enter into successful and profitable competition. He had had considerable experience with the Diesel oil-engine, having had one under his supervision for nearly two years; but its economy was not better than the case he had cited, and the capital cost was much greater than for an ordinary Otto gas-engine, plus the suction gas plant.

**Mr. Taylor** made the following remarks in his reply to the discussion. With reference to the objections that had been raised to cutting off the supply at certain fixed times, he thought the best answer he could give was to call their attention to the places where this system had been successfully adopted. At Brighton they were selling 750,000 units simply and solely by this method, using time switches made by the Reason Manufacturing Company. In Montreal 30 per cent. of the motor load was connected on this system. The

Digitized by Google

motor load was something approaching 18,000 kw., so that meant about 5,000 kw. so connected. In reply to Mr. Jeckell, he had assumed, for the purpose of comparison, that 1 b.h.p. required one unit. Mr. Jeckell's figures worked out to ·385 unit per horse-power hour, which seemed to point to his having over-estimated the number of horse-power hours obtained from his motor, as even ·746 unit per horse-power hour gave an efficiency of 100 per cent. Mr. Jeckell's deductions from his figures for capital cost charge were also four times too high as he had omitted to note that the motor, as stated in the paper, was working on the average at a quarter of its full load. In reply to Mr. Shawfield, he might say that in calculating the charge to the consumer under case 1 he had considered a small lighting station of 2,000 kw. capacity, with no traction load. He had taken ·7d. as being an average figure for the works cost; but if this could be reduced, the charge per unit could be improved upon. Mr. Shawfield had misunderstood him about the diversity factor. It is only the extreme possible limit of the diversity factor (for a particular class of motor) which is the reciprocal of the load factor, the latter being taken only over the working day, not over the night as well. The actual diversity factor will be anything between unity and this limit. If the limit, for example, is 4, as in case 2 of the paper, it is extremely unlikely that the actual figure will reach 2, and hence 1·5 is a safe value to estimate upon. In reply to Mr. Morcom, the author said that the proposed system of charging was now actually in use on a large scale, which showed that it was quite practicable. Mr. Fennell's remarks bore testimony to the success of this method; and the instances he had mentioned as likely customers might all use power up to 30 h.p., as at Brighton. In reply to a written communication from Mr. Pringle, Mr. Taylor said that the figure he had assumed of £70 per kilowatt in Fig. 9 was for cost of new station and mains, not for cost of extending, but probably the latter was the more correct way of looking at it. In reply to Mr. Wilson, he wished he could endorse his statements; but all he claimed in the paper was that for intermittent loads, and for units not larger than 5 h.p., electricity made the best showing. Only in favourable cases would continuously-loaded motors show so well. As regards Blackheath, he thought that it was a most unsafe proceeding to allow consumers to remain on the cheap rate till such a late hour as 5 p.m., and he understood that at Aston, at any rate, the motor and lighting loads had clashed to a very considerable extent. It was very desirable to know the consumer's diversity factor as well as his load factor; not necessarily with a view to charging him at a different rate, but in order that the cost to the station of each consumer should at least be accurately known, so that, if a flat rate be adopted, the most favourable class of load may be diligently fostered.

## APPOINTMENTS VACANT.

**Assistant in Charge of Meter Department,** Hammersmith. Commencing salary, £2. 10s. per week. Applications by Jan. 18. See advertisement in last issue.

**Three Electrical Engineering Assistants,** City and Guilds Central Technical College. Salaries commencing respectively at £200, £150, and £150 per annum. Apply to Prof. Ayrton, Exhibition-road, London, S.W. See advertisement in last issue.

**Second Assistant Electrical Engineer,** Bradford. Salary, £250 per annum. Applications by Jan. 19. See advertisement in last issue.

**Improver,** Stretford Urban District Council. No premium required. See advertisement in last issue.

**Switchboard Attendants** Wages, 20s. per week. See advertisement in last issue.

**Electrical Adviser.** The Secretary of State for India has sanctioned the appointment of an adviser on electrical matters to the Government of India at a salary commencing at £70 per month, rising to £110. Private practice will be allowed, but not for municipalities or district boards, as it will be part of his regular duties to advise such bodies.

**Switchboard Attendant,** Devonport electricity works. Wages, 30s. per week. Applications to the Borough Electrical Engineer. See advertisement.

**Shift Engineer,** Reading tramways power station. Salary to commence at 35s. per week. Applications by Jan. 18 to the General Manager and Engineer. See advertisement.

**General Manager,** Southampton tramways. Salary £400 per annum, rising by £25 a year to £500.

**Assistant Electrical Engineer.** The Electric Lighting Sub-Committee of the Whitby Urban District Council have recommended the appointment of an assistant electrical engineer to take full charge in the absence of Mr. L. H. King, resident engineer, at a commencing salary of £104, rising by annual increases of £4 to £120 per annum.

## PERSONAL.

The President of the Board of Education has appointed the Right Hon. R. B. Haldane, K.C., M.P., to be chairman of the Departmental Committee which is enquiring into the present and future working of the Royal College of Science and Royal School of Mines, South Kensington, in place of Sir Francis Mowatt, G.C.B., late Secretary to the Treasury, who, while remaining a member of the committee, has resigned the chairmanship owing to complications having supervened on his illness which were not previously anticipated.

The Middlesbrough Corporation have decided to advance the salary of Mr. Telford, chief assistant of the electricity department, from £150 to £165 per year, and the salary of Mr. Scotson, mains superintendent, from £2. 5s. to £2. 10s. per week.

The South Metropolitan Electric Light and Power Company, Limited, inform us that Mr. Wm. May, of 18, Austin-friars, has been appointed a director of the company.

Mr. Lewis D. Landay, an American electrical engineer, who has been resident in London for a number of years, has been appointed general manager of the Singapore Electrical Tramways Company.

The Chesterfield Town Council have appointed Mr. R. L. Acland, the electrical engineer, to the joint offices of electrical engineer and manager of the tramways department at the salary of £350 per annum, rising to £400 at the expiration of a year if satisfactory.

Mr. R. B. Leach, late chief assistant engineer, has been appointed chief electrical engineer and manager to the Farnworth Council.

Mr. J. H. Fooks Bale has commenced his duties as electrical engineer and tramways manager at the Urban District Council electricity works, Walthamstow.

Mr. A. V. Wardrop, formerly of the Corporation electricity works, York, has been appointed electrical engineer to the Elland Urban District Council.

## FORTHCOMING EVENTS

FRIDAY, JAN. 13.

**Tramways and Light Railways Association.**—At 8 p.m., "Overhead Equipment," by Mr. H. M. Sayers.

**Junior Institution of Engineers.**—At 8 p.m., "The Theory of the Incandescent Mantle," by Prof. Vivian B. Lewes.

**Institution of Electrical Engineers (Manchester Students' Section).**—"Electric Heating," by Mr. A. E. Jepson.

**Institution of Civil Engineers (Students' Section).**—"Theory of Electricity and Magnetism," by Mr. J. Swinburne.

SATURDAY, JAN. 14.

**Birmingham Electric Club.**—At 7.30 p.m., "Aluminium and its Electrical Properties," by Mr. W. Smith.

MONDAY, JAN. 16.

**Tramways and Light Railways Association.**—At 3.30 p.m., visit to the works of the Central London Railway Company, Oxford-circus Station.

TUESDAY, JAN. 17.

**Institution of Civil Engineers.**—At 8 p.m., "The River Hooghly," by Mr. L. F. Vernon-Harcourt.

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Electric Driving in Textile Factories," by Mr. H. W. Wilson.

WEDNESDAY, JAN. 18.

**Society of Arts.**—At 8 p.m., "Wireless Telegraphy and War Correspondence," by Captain Lionel James.

**Chemical Society.**—At 5.30 p.m., general meeting.

**Royal Meteorological Society.**—At 7.30 p.m., "The Connection of Meteorology with other Sciences," by Captain D. Wilson-Barker.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "The Construction and Maintenance of Large Telephone Exchanges," by Mr. A. L. Stanton.

THURSDAY, JAN. 19.

**Rugby Engineering Society.**—At 8 p.m., "A Novel System of Electric Traction," by Mr. H. S. Meyer.

FRIDAY, JAN. 20.

**Institution of Mechanical Engineers.**—At 8 p.m., "Some Impressions of American Workshops," by Mr. A. J. Gimson; "Waterworks Pumping Engines in the United States and Canada," by Mr. John Barr; "Some Features in the Design and Construction of American Planing Machines," by Mr. A. Kenrick, jun.; "Engines at the Power Stations and at the St. Louis Exhibition," by Mr. Alfred Saxon.

**Royal Institution.**—At 9 p.m., "New Low-Temperature Phenomena," by Sir J. Dewar.

**North-East Coast Institution of Shipbuilders and Engineers.**—At Newcastle, general meeting.

SATURDAY, JAN. 21.

**Glasgow Technical College Scientific Society.**—At 7.30 p.m., "Notes on Tool-Room Organisation and Practice," by Mr. G. Blair.

Jan. 25.—Birmingham Section (postponed from Jan. 18).

Jan. 27.—Municipal and County Club, house dinner.

Jan. 27.—The following papers will be read at the Physical Society: "Action of a Magnetic Field on the Discharge through a Gas," by Dr. R. S. Willows; "Action of Radium on the Electric Spark," by Dr. Willows and Mr. J. Peck; "The Slow Stretch in India-rubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

**Lancashire and Yorkshire Railway Company.**—At a special meeting of this Company held at Manchester on Wednesday, proposals for merging the 3 per cent. preference stocks of 1897 and 1899, amounting together to £22,724,000, with the consolidated preference stock, amounting to £22,676,900, were adopted.

# LEGAL INTELLIGENCE.

## EMPLOYERS' LIABILITY ACT.

At the Brompton County Court on Tuesday, before Judge Stonor and a jury, Burt Scott Phillips, electrical fitter, brought an action under the Employers' Liability Act against the Underground Electric Railway Company. The plaintiff's claim was in respect of personal injuries said to have been sustained owing to negligence on the part of the defendants.

Plaintiff was assisting in raising some heavy iron pipe sections on to a temporarily constructed staging. He had been ordered by the "charge hand" to get upon the staging, so as to be ready to also assist in placing the section in proper position. The pipe had been raised a little higher than the staging when the rope suspending it suddenly broke. The fall of the pipe caused the staging to collapse, and plaintiff and two other men fell some 30ft. on to a cement floor.

**Counsel** for the defendant admitted that the rope was unfit for the job, but he submitted that the plaintiff himself was guilty of contributory negligence in having selected and used the rope in question.

The **Plaintiff** bore out his counsel's opening statement, and in cross-examination maintained that it was not a fitter's duty to select the rope in such work as that in question, except when there was no "charge hand." He denied having been promoted to the position of a "charge hand."

For the defence, **Stephen Mathison**, the "charge hand" referred to, said it was the duty of a fitter to see that proper ropes were used in the work, but if the fitter had any doubt about the fitness of the rope, it was his duty to refer the matter to the "charge hand." The plaintiff on the occasion in question did not refer to him any question about rope.

The jury returned a verdict for the plaintiff, assessing the damages at £200.

## TRAMWAY ACCIDENT.

At the Bradford County Court, before his Honour Judge Bompas, K.C., James Arthur Firth brought an action against the Corporation to recover £30 for personal injuries alleged to have been caused by the negligence of the defendants. Mr. W. Walker appeared for the plaintiff, and Mr. Harold Newell represented the Corporation.

**Mr. Walker** stated that the plaintiff was driving across Leeds-road a horse attached to a one-horse block cart, such as is used by builders. As he was crossing from Thornbury-road to Thornbury-street a tramcar came along Leeds-road, travelling in the direction of Bradford. The car was 40 yards away when the cart was about to cross the tramlines, and there appeared to be plenty of time for the plaintiff to get over. Accordingly he proceeded to drive the horse across. He got clear of one set of metals and had almost cleared the second set, when the car came in contact with one of the "dogs," or buffers, that projected from each side of the cart. The plaintiff was in consequence thrown to the ground, and one of the wheels of the cart passed over his shoulder. He suffered injuries to the left hand, his shoulder, and other parts of the body. His forefinger was lacerated, and he was unable to attend to his work for eight weeks.

**Mr. Newell** intimated that there was no dispute about the injuries or the amount of the damages.

Evidence having been given in support of the plaintiff's case, **His Honour**, in summing up, remarked that there was no doubt that there was time for the plaintiff to get across the lines. He thought, however, that drivers of tramcars should allow a fair distance to a cart that was passing in front. He did not think this was a case of a horse suddenly turning stupid and stopping, and he must give his verdict for the plaintiff for the amount claimed.

## TRAMWAY FARES.

Thomas Wilkinson was summoned at Wallsend on Tuesday for having travelled on the Tyneside Tramway Company's service without paying his fare.

The defendant and another man entered a car at Gosforth, and Wilkinson paid for two 2d. tickets. When the car arrived at Bigges Main the conductor told them that was the end of the 2d. stage, and that if they were going on to Wallsend another penny from each would be required. The man with Wilkinson paid the extra 1d., but defendant refused.

**Wilkinson** denied that he had not paid the right fare as shown by the company's bills, contending that when he paid 4d. for the tickets at Gosforth he and his friend were entitled to travel to Wallsend.

The Bench fined defendant 10s. for refusing to pay the fare from Bigges Main to Wallsend.

**Defendant** said it was a serious miscarriage of justice.

The **Chairman** replied that Wilkinson could, if he thought fit, take the case to a higher court.

# CONTRACTS FOR ELECTRICAL SUPPLIES.

**Halifax.**—The Corporation invite tenders for coal conveyors. Tenders by Jan. 31.

**Tourney.**—Tenders are required for the electric lighting of the waterworks. Tenders by Jan. 20.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**West Hartlepool.**—The Corporation require tenders for additional 250-kw. set, with the necessary switchboard, panel, etc.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Paris.**—The Under-Secretary for Post and Telegraphs, 103, Rue de Grenelle, requires tenders for accumulator batteries. Tenders by Jan. 18.

**Bucharest.**—The Government require tenders for the annual supplies to the Regie for lighting materials and accessories. Tenders by Feb. 7.

**Kirkcaldy.**—The Town Council invite tenders for the extension of about 500ft. in length of the present East Pier. Tenders to the Town Clerk by Feb. 4. See advertisement.

**Giurgu (Roumania).**—Tenders are required for a concession to establish electric lighting in the town. Particulars may be obtained from the Mayor. Tenders by Jan. 28.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Vienna.**—Tenders are required for telegraph and telephone materials. Particulars may be obtained from the K. K. Post Oeconomie-Verwaltung, Vienna. Tenders by Jan. 31.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Caen (France).**—The Prefect requires tenders for concession of a tramway from Eyes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1.

**Grimsby.**—The Corporation invite tenders for (No. 30) motors; (31) water-purifying plant; and (32) 12 months' supply of stores. Tenders for 30 and 31 by Jan. 23, those for 32 by Feb. 1. Particulars in advertisement columns.

**Port Elizabeth.**—Messrs. Davis and Soper, 54, St. Mary-axe, E.C., agents of the Municipal Corporation of Port Elizabeth, South Africa, invite tenders for various works in connection with the Corporation electricity supply undertaking. Tenders by Jan. 16, 1905.

**Pudsey.**—The Corporation invite tenders for underground electric mains, switchboard, etc. Specifications, etc., may be obtained on application to Messrs. Shepherd and Watney, consulting engineers, Greek-street-chambers, Leeds. Tenders to the Town Clerk by Jan. 20.

**Gravesend.**—The Education Committee invite tenders for the electric lighting of King-street National School. Specification and form of tender may be obtained on application to Mr. C. F. McInnes, Electricity Works. Tenders to Mr. H. H. Brown, town clerk, by 16th inst.

**London, N.**—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Northern Hospital, Winchmore Hill, N., in accordance with plan and specification prepared by Mr. W. T. Hatch, M.I.C.E., M.I.M.E., engineer-in-chief. Tenders by 10 a.m. on Jan. 24.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £219,600 is to be expended on rolling-stock.

**Swindon.**—The Corporation invite tenders for the supply and erection of one 30ft. by 8ft. Lancashire boiler with down-take superheater, steam, exhaust, and feed piping, etc. Tenders to be delivered before 10 a.m. on Tuesday, Jan. 24, 1905, to Mr. Robt. Hilton, town clerk. See advertisement in last issue.

**Drax (near Selby).**—Tenders are invited for electric light installation, also electric pump, etc., capable of delivering 500 gallons per hour, at Read's Grammar School. Apply to the headmaster, Mr. W. St. G. Drennan, at the School, who will supply all necessary particulars. Tenders to be delivered to Messrs. E. and T. Clark, solicitors, Snaith, R.S.O., clerk to the Governors, by noon on 28th inst.

**Johannesburg.**—The Council invite tenders for Vignoles rails, fishplates, angle steel guard-rails, bolts, nuts, coach screws, and dog-spikes. General conditions, specifications, and forms of tender may be seen at the offices of the Council's consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and may be obtained on payment of five guineas. Tenders by Jan. 26.

**South London Electric Supply Corporation.**—The Directors invite tenders for the construction, supply, and erection at their works at Bengeworth-road, Loughborough Junction, S.E., of one 750-kw. steam alternator with pipe connections and sundry ironwork. Sealed tenders must be forwarded to the secretary of the company, Mr. H. H. Boyer, Bengeworth-road, Loughborough Junction, S.E., before noon on Jan. 16.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**Plasencia.**—Tenders are required for the concession for 10 years of the lighting by electricity of the town. Adjudication of tenders will take place on Jan. 28, and tenderers, if not appearing in person, must be represented by a duly authorised agent. The conditions of concession are set out in the notice in the *Gaceta*, which may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

**Melbourne.**—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be

Digitized by Google

seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess, M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

## RESULTS OF TENDERS.

**Middlesbrough.**—The Electricity Committee report that the tender of Messrs. Edward le Bas and Co., amounting to £760, for the pipework in connection with the works extension has been accepted.

**Whitby.**—The Urban District Council have accepted the following tenders: Parsons, for the installation of a 200-kw. steam-turbine at £1,550, and Johnson and Phillips for an additional panel to the switchboard at a cost of £92. 10s.

**Swansea.**—The Swansea Telephones Committee have accepted the tenders of the British Insulated and Helsby Cables, Limited, for the extension of the switchboard accommodation and the supply of fresh cables at £270 and £194 respectively.

**Eccles.**—The Town Council have accepted the tender of the Gilbert Arc Lamp Company for five arc lamps and switchgear at £56. 19s., and that of Messrs. Phillips and Hilkirk for three Gilbert arc lamps and four arc-lamp brackets for the sum of £24. 7s. 6d.

**Canterbury.**—The Lighting Committee recommend that the tender of Messrs. Harris Bros., at £390. 11s. 6d., be accepted for boiler and engine foundations. The City Council accepted the following tenders for the supply of the electricity plant: Davey, Paxman, and Co., new boiler and superheater; Dick, Kerr, and Co., new 300-kw. steam dynamo; J. G. Statter and Co., switchboard; E. Green and Sons, extensions to economiser.

**Condensing Plants.**—The Mirrlees-Watson Company, Limited, engineers and founders, Glasgow, report the following orders for surface condensing sets: British Thomson-Houston Company, for County of London Electric Supply Corporation—two sets—(duty per set in pounds of steam per hour, 29,250); Alfred Parry, Manchester, for Calcutta (7,500); Trafford Power and Light Supply Company, Manchester, per Lacey, Sillar, and Leigh (24,000); J. and P. Coats, Limited, for Barcelona (25,500); British Thomson-Houston Company, for London (27,000); Crewe Electricity Works, (20,000); Gwynne's, Limited, London (6,000).

**Admiralty Contracts.**—Messrs. Graham, Morton, and Co., Limited, engineers and contractors, Leeds, have just obtained the contract for the supply, delivery, and erection at the electrical generating station at H.M. dockyard, Devonport, of a complete coal-handling plant, including coal-bunkers, stanchions, girders, flue, and coal-measuring and weighing apparatus, and all accessories appertaining to same. The Lancashire Dynamo and Motor Company, Limited, Trafford Park, Manchester, have received from the Admiralty the order for the equipment of Bull Point Dockyard, also the contracts for the equipment of Sheerness and Malta Dockyards—the total value of the three contracts being upwards of £75,000.

# BUSINESS NOTES.

## TRACTION.

**Perth.**—The Town Council have decided to extend the tramways to the Dankeld-road district at a cost of £4,500.

**Dover.**—The Corporation have passed a formal confirmatory resolution concerning the tramway extension by the requisite two-thirds majority.

**Aberdare.**—The tramway and dust destructor scheme, of which particulars were given in our last week's issue, has been approved by a public meeting.

**Kirkcaldy.**—In response to the projected tramway, to which we have referred in previous issues, the Fife County Council have now given their approval.

**Underground Electric Railways Co.**—At a meeting of the directors of this company Lord George Hamilton, M.P., and Mr. J. Clifton Robinson were elected directors.

**Leeds.**—One of the steam-pipes at the power station gave out on Saturday evening, with the result that the service had to be reduced. After the traffic was over the defect was speedily remedied.

**Bury.**—It is reported that when the resolutions passed by the Corporation at a special meeting last week in favour of tramway extensions and other schemes came up for confirmation they were rejected.

**Glasgow.**—In deference to the views of a number of owners and occupiers in Wilton-street, the Corporation have decided that the proposed tramway in that street shall be abandoned, at any rate for the present.

**Manchester.**—The Urmston District Council have appointed a committee to enter into negotiations with the Corporation with respect to the proposed construction of tramways in Urmston. A conference has been fixed for an early date.

**The Conduit System.**—The Board of Trade, after full consideration of the question, have approved the use of a slot not exceeding 1in. in width in connection with the conduit system for the electrification of the London County Council tramways in North London.

**Cupar.**—The District Committee of the County Council have appointed a committee to consider the question of a light railway from Falkland to Falkland-road Station. The distance is 3½ miles, and the cost of the permanent way is estimated at about £10,500.

**Wigan.**—The Corporation having asked the Aspull District Council for consent to the extension of the tramways to the Finger Post, and enquiring upon what terms they would agree to the widening of Spring Bridge, the District Council have given instructions for an estimate to be prepared.

**Lowestoft.**—The Tramway Committee having reported that the matter of the construction of the East Anglian light railway had been discussed, the town clerk was directed to write Messrs. Hawtayne and Zeden on the matter, with a view to Messrs. J. G. White and Co. interviewing the committee.

**Victoria.**—The Legislative Assembly has referred to the Railways Standing Committee the question of constructing an electric street railway along the eastern foreshore to St. Kilda and several sections within the metropolitan area. It is reported that a private promoter has offered to undertake the system.

**Dundee.**—The trams again show substantial progress on the year's working. During 1904 the number of passengers carried was 11,511,716, an increase of 326,681 as compared with the previous 12 months, while the sum realised in fares was £44,036. 9s. 8d., representing an advance of £667. 3s. 11d. over the last annual return.

**Wednesbury.**—It was reported a little time back that there was some likelihood of the difficulty between the local authorities and the company being settled. Little, however, appears to have been done so far. It is stated that plans have been drawn up for relaying and re-equipping the lines when a settlement of the existing dispute has been arrived at.

**Linlithgow.**—At a meeting of the District Committee of the County Council on Monday a letter was read from Mr. Macnaughton, of Edinburgh, as to an electric tramway between Edinburgh and Queensferry, and asking the District Committee to arrange for an interview with the promoters at an early date. The committee appointed representatives for this purpose.

**Stockport.**—In connection with the taking over of the Hazel Grove Company's system, it has been decided that the Edgeley route shall be extended to Dale-street, and be laid as a double line throughout; also that the tramway into St. Petersgate shall be constructed along Wellington-street and Lord-street. The town clerk has been instructed to furnish a definition of "workmen" to the committee.

**Bradford.**—At the meeting of the Corporation it was reported that the town clerk had taken expert advice which showed that there was no basis for the claim of Messrs. Smith and Illingworth in respect of alleged infringement by the Corporation of their patent for car-top covers. The claim has therefore been repudiated. A line from Odsal Top to Cleckheaton-road has been suggested. The question of ½d. fares is under consideration.

**Hastings.**—A memorial alleging non-compliance with the Standing Orders has been handed in at the Private Bill Office on behalf of the Bexhill Corporation against the Hastings Tramway Company. The memorial will come before the Examiner of Private Bills on the 18th inst. At the meeting of the Corporation last week the provisions of the company's Bill came up for consideration on the minutes of the Tramways Committee. It was resolved that the clauses relating to the use of the overhead system along the front and to a proposed extension of time for completing certain routes could not be assented to. Probably a conference will be held between the committee and company in the course of a few days.

**Private Bills.**—The period allowed for depositing memorials alleging non-compliance with the preliminary Standing Orders in respect of any of the first 100 Bills on the general list of constructive measures relating to public and private works has expired. Only five memorials were lodged—by the Willesden Council against the Metropolitan Electric Supply (Various Powers) Bill; by the Great Northern Company of Ireland against the Mullingar, Kells, and Drogheda Railway Bill; by the Northamptonshire County Council against the Wellingborough and District Tramroads and Electricity Supply Bills; by the Willesden Council against the Metropolitan Railway Bill; and by the Bexhill Corporation against the Hastings Tramways Bill.

**District Railway.**—The Metropolitan District Railway Company has deposited a Bill for next session, the effect of which will be to empower it to raise £400,000 towards the general purposes of the

Digitized by Google

undertaking, the cost of adapting the railway for electrical working, providing for any loss on the sale of rolling-stock or plant, and in payment of arrears on the guaranteed stocks. The preamble explains that this sum represents the estimated cost of constructing so much of the railway authorised in 1897 and 1903 which has now been transferred to and is now in course of construction by the Great Northern, Piccadilly, and Brompton Railway Company. This sum not being now required for the purpose for which it was originally sanctioned, is needed for other purposes.

**Belfast.**—The question of passes for members of the Corporation and for the police threatened a little storm at last week's meeting, but in the end it was decided to present each councillor with a pass, and terms will probably be arranged with the police authorities. At a meeting of the Tramway Committee a lengthy communication was read from Messrs. J. G. White and Co., Limited, in reference to the contract and the delay in signing it, and to some of the specifications as to which there had been differences in detail. Considerable discussion took place, and the following resolution was adopted: "That the letter of Messrs. J. G. White and Co., Limited, be referred to the surveyor, electrical engineer, and general tramways manager, with the aid of the town clerk, for consideration and to report, and that one of the firm of consulting engineers, Messrs. Lacey, Sillar, and Leigh, be requested to attend here, if necessary, and to advise with the officers on the question raised. That Messrs. White be informed that the time for performance of the contract must date from the acceptance of their offer."

**West Hartlepool.**—At a meeting of the Corporation the Works Committee reported that a letter was received from the tramway company submitting proposals for settlement of the complaints with reference to the condition of the track, to the effect that the Corporation should waive the right of purchase of the several lines in the borough until 1919, the tramway company at the same time to agree to a reduction of tenure of the Seaton Carew line to that date. The company would then reconstruct the permanent way and the overhead equipment in the early spring. A further letter was received from the company to the effect that they would use their best endeavours to obviate the noise alleged to be made by the cars, but repeated their contention that they were not liable for the sanding of the track where the same is dangerous to traffic through the slipperiness of the wood blocks. The Corporation approved the committee's refusal of these terms, and the notice given to the company that the latter must carry out the several obligations imposed upon them with reference to the matters named under the Acts and orders affecting the company's operations. It has been decided to again institute proceedings against the company to enforce the penalties incurred for not maintaining the track in good repair, for not putting sand upon the wood pavement when slippery, and for not removing the cause of the complaint as to the noise caused by the rattling of the machinery of the cars.

**Adelaide.**—The report of Mr. F. E. Bradford on the electrification of the Adelaide suburban railways, which was laid on the table of the South Australian Assembly, shows that electric traction applied to the line to Glenelg and the Port, Semaphore, and Largs system, besides paying interest on the cost of conversion, would result in an increase of the present profit by £8,912, or a total profit of 3·8 per cent. The cost of conversion is estimated at £151,830, not including power station. A power station large enough to supply power for the above-mentioned lines, and also for the Adelaide tramway system, will cost £882,000. Mr. Bradford thinks the present traffic would be increased by 25 per cent., due to the greater frequency of service, higher speed and greater comfort to the travelling public; but taking 10 per cent. as a safe and conservative estimate, the increase on the present profit would be £17,732, or 7·5 per cent. on the capital. The services would be more frequent and faster than at present, and the train mileage on the Port and Semaphore line would be 50 per cent. more and on the Glenelg line 100 per cent. more than at present. The power station is to be located at Port Adelaide to generate power for all the lines converted, and for the proposed Adelaide tramway system as well. The cost of producing power with the plant recommended by Mr. Bradford, with an output of 10,000,000 units per annum, will not exceed ·4d. per unit, including interest on the cost of construction.—*New South Wales Railway Budget.*

**Bournemouth.**—The Corporation have passed the following resolution: "That this Council has heard with satisfaction the award made by Mr. Justice Lawrence on the recent tramway arbitration, and recognising that the favourable result obtained is largely due to the able and zealous services of the town clerk, the borough engineer, and the chairman of the Tramways Committee, hereby tender its special thanks to those gentlemen for the services rendered by them." The chairman and vice chairman have been appointed a sub-committee to enquire, with the help of the borough engineer and traffic manager, into the feasibility of establishing a regular service of cars between Southbourne and Christchurch Station in connection with the trains. Councillor Elcock enquired if the Council had power to take a poll of the town as to whether the ratepayers were in favour of Sunday trams. The Town Clerk replied that he did not consider any money the Corporation had control of could be legally expended in taking a poll. The committee have replied to a letter from the Malmesbury Park, etc., Ratepayers' Association that they are unable to reconsider their decision as to reducing fares for children. It has been decided to lay the lines up to within a few feet of the borough boundary, and that the surveyor be authorised to arrange, if possible, with the company and the local authorities concerned to make or allow the Council to make their line complete to the borough boundary, but without making any actual connection. The Corporation have replied to the Roads Improvement Association that they do not consider it necessary to transfer to the side of the road the central standards on the line from the Hotel Metropole to Boscombe Hill.

**Swansea.**—An important conference between the Parliamentary Committee of the Corporation and the Swansea Manufacturers and Traders' Association has taken place respecting the new Parliamentary Bill. The association was formed a few weeks ago "to protect the interests of Swansea ratepayers and to ensure the strictest economy compatible with efficient administration of local administration." In regard to the proposals to compulsorily acquire the tramways and widen Castle-lane there was much discussion. The association made it clear that there could be no objection to the Corporation securing an option to purchase the tramways, but it was questioned whether, having regard to the new parallel lines that were now laid down in the centre of the town, the system would be remunerative. On that ground the manufacturers and traders seemed averse to the Corporation rushing into a speculative undertaking, and stated that the views of the ratepayers ought to be obtained before the Corporation is committed to the purchase. It was agreed that the town clerk should take the opinion of counsel as to whether a clause can be inserted in the Bill providing that there shall be a poll of the ratepayers before the Corporation exercise any powers of purchase of the tramways. Draft copies of the proposed leases to the tramways company of the new tramways have been circulated amongst the Council members. The Brynhyfryd section comes under the Tramways Act, and the remaining sections under the light railways orders. Regarding the latter the rent to be paid by the company is to be as follows: an amount equal to the interest which the Corporation have to pay on capital property expended in construction, together with further sum equal to 3 per cent., and in the event of the company paying interest on capital expended on the existing tramways and proposed light railways, amounting to 6 per cent., the company to pay to the Corporation a further sum equal to 1 per cent. per annum. With regard to the Brynhyfryd section, the rent paid is to be as follows: for the first seven years of the lease a sum equal to 5 per cent. upon the capital expended; for the next seven years, 6 per cent.; and for the remainder of the term, 7 per cent. In both instances all rates, charges, assessments, impositions, and outgoings in respect of the tramways and light railways to be paid by the company. In the case of the Morriston section the company are to work this from the Corporation electricity supply, and the following are the prices to be charged for the whole supply of electrical energy: for a minimum of 200,000 units per annum, 1½d. per unit; for the next 150,000 units, 1$\frac{5}{8}$d. per unit; for the next 150,000 units, 1¼d.; for the next 150,000 units, 1$\frac{1}{8}$d. per unit; and for the next 150,000 units, 1d. per unit. All the extra number of units over the 200,000 must be supplied in the same year in order to get the reduced scale of charges. It was stated in committee last week that Messrs. Dick, Kerr, and Co. had two-thirds of a mile more tramways extension to complete, and that the date on which the cars would be running depended on the completion of the lease to the company. The receipts for 1904, less one day, were £27,994, an increase of £864 over 1903.

**South Africa.**—Progress in electric traction receives considerable attention in the current number of the *British and South African Export Gazette*. The completion of the Durban Corporation's tramway system is still productive of fresh orders, and others are likely to follow as unexpected developments occur. For an increased supply of current during certain hours of the day a large storage battery and complete booster equipment has been ordered, the former having been placed with the Tudor Storage Battery Syndicate and the latter with the Lancashire Dynamo and Motor Company, Limited. The battery will consist of 250 cells of a current capacity of 770 amperes per hour. Progress is being made with the various extensions into the outskirts of the city, the work of doubling the single track in the Berea-road, one of the busiest sections of the system, having been commenced. Underground lavatories here, and probably at Greyville, where a sub-station is to be erected, form part of the projected improvements. Extensions of the system to the Park and the Dorp Spruit are also under weigh, while the tenders for the ironwork for the Victoria Bridge, in connection with the latter, are about to be invited. The Pietermaritzburg electric tramway system, begun in September, 1903, was successfully inaugurated in November last, the cost being £105,000. Only part of the system is actually working, bridge construction in one case causing delay, but the whole network will probably be in active operation within a month or two. As in other cases, necessity for extension of the original plans is already being felt, and several short additions are now being considered, involving fresh calls for permanent-way material. The tramway manager has also pointed out the necessity for ordering four more cars, thus bringing the total up to 16. Cabled instructions to the London agents, Messrs. Ford Bros., are expected to be transmitted almost immediately. Although long talked of, electric tramways have not hitherto entered into the programme of Bloemfontein's urgent public requirements, but the recent proposals of a syndicate to lay down an electric tram service under a concession, and an alternative proposition to start a service of motor 'buses, have both been rejected by the Corporation, who are now considering the feasibility of the establishment of municipal tramways on a proper system. The completion of the other public works now in hand may defer a move in this direction for the present, but realisation of such a scheme is regarded as one of the certainties of the early future. The tramway to Alexandersfontein, which the De Beers Company had under construction, has now been completed, and only awaits the rolling-stock. The company have spent about £165 000. The large power station which supplies the current to light Kimberley is also completed, while the supply to the township of Beaconsfield was turned on in October last. A dispute between the Beaconsfield Town Council and Messrs. Gibson Bros. over the royalty to be paid for 1½ miles of tramline under their control, is temporarily delaying the completion of the works. A project for constructing a six-mile electric, steam, or oil-driven tramline from Hillarys, a station on the Natal main line, to the Bellair estate, and supplying light and power to the district traversed, is in the course of arrangement. Parliamentary powers are to be applied for in the next session of the Legislative Assembly, the promoters of the scheme being Messrs. Benjamin Hampson and W. W. Cato, both of Durban. The electrification

Digitized by Google

the Springs-Randfontein line of the Central South Africa Railways, to which we referred recently, appears to have been shelved.

**Colchester.**—At last week's meeting of the Corporation the Tramways Committee, having regard to the importance of the decision to be arrived at relative to the proposed extension of the tramway system, submitted a special report giving the principal facts bearing upon the proposal, and a statement of the receipts and outgoings in connection with the tramway undertaking up to Dec. 29. The suggested extension would commence at a junction near the bottom of Military-road with the line in Magdalen-street, and would terminate near the main entrance to the recreation ground, the length being slightly over half a mile. The original proposal as made to the Council was to carry the extension as far as Old Heath, but the committee, on examining with much care into details, came to the conclusion that it is not yet time to extend the system in this direction beyond the point they recommend. The needful expenditure in respect of the permanent way, overhead equipment, and feeders is estimated by the borough engineer and borough electrical engineer at £6 134. To this must be added the cost of new cars, £1,200, and that of the provisional order, approximately £350, making in all £7,684. Of this total sum £1,300 has already been expended by the Council in the purchase from Messrs. White and Co., contractors for the original works, of rails, setts, tiebars, and other materials. These rails and other materials were purchased on very advantageous terms. The committee direct attention to the circumstance that no additional plant would be requisite for the supply of power, and, further, that staff expenses would not be substantially increased—certainly not nearly in proportion to the very considerable augmentation of income which it is believed would result. The area which would derive the greatest direct accommodation from the new section is one of the most populous in the borough, and is at present, to a large extent, cut off from any ready participation in the benefits which the tramway system affords. A careful survey of the district has been made, and the inhabitants may be taken at 7,000, exclusive of the military population of the camp, and the population will probably be largely increased in the immediate future by reason of the development of a portion of the Winsley Charity estate and other properties in the vicinity. Besides this, many thousands of persons resort to the public recreation ground. In the committee's view the length of line proposed would be more remunerative, possibly, than any other route (save, perhaps, that between North Hill and the North railway station) at present embraced within the system, and would be a valuable factor in the successful progress of the undertaking. The success of the tramways, and the benefits which they have conferred upon all classes of the community, have greatly exceeded what were originally anticipated. The system was not opened until July 28, and thus only two of what may be termed the most favourable months of the year have been experienced. Notwithstanding this the weekly average number of passengers carried has been 60,382, and the total number of passengers during the five months since the opening has been 1 337.098. Up to Dec. 29 the accounts show a surplus of about £180. In support of the proposed extension a deputation of the inhabitants attended the meeting, and their spokesman showed that he had studied the question minutely by producing copious figures, the result of his own enquiries. As on a previous occasion, however, a portion of the Council were remiss in their attendance, and as the requisite two-thirds were not available the scheme had to be postponed to a special meeting, for which the mayor has issued a "whip."

## LIGHTING AND GENERAL.

**Arbroath.**—An early settlement of the electric lighting question is anticipated.

**Chili Telephone Co.**—The directors have declared an interim dividend of 3s. per share.

**Norwich.**—The Corporation have reduced the charge for electric light from 5d. to 4½d. per unit.

**Frome.**—Application is to be made for a loan for the purchase of electric pumps at the sewage works.

**Barrow.**—The Town Council have received sanction to borrow £35,000 for electric lighting purposes.

**Swindon.**—Application is to be made for sanction to a loan of £2,000 for arc lamps and small motors.

**Sale of Plant.**—Particulars of sales of cables, induction coil, and trolley standards will be found in another column.

**Globe Telegraph and Trust Co.**—The directors have declared an interim dividend of 2s. each on the ordinary shares.

**Lowestoft.**—A recommendation that more boiler power be provided at the electricity works at a cost of £1,000 is before the Electricity Committee.

**Hampstead.**—For £12,000, being the profits of its electrical undertaking, the Borough Council are purchasing the business of the North-West London Electric Supply Company.

**Engineers' Overalls.**—Messrs. W. J. Ward and Co., 14, Clayton-street, Newcastle-on-Tyne, are making a speciality of American cut dungaree overalls for engineers, motorcar drivers, etc.

**Yarmouth.**—Application is to be made for a loan of £10 000 for new plant, including another 300-kw. engine and dynamo and boilers at £4,500, and an additional water conduit, estimated to cost £3,500.

**Transvaal.**—A meeting of shareholders in the electric light company at Potchefstroom has agreed to the draft deed of sale, whereby the electric plant is municipalised at a cost of £6,000.—*South African World*

**Blaydon.**—The Durham Electrical Power Distribution Company, Limited, have approached the Council with regard to the supply of current under the Blaydon electric lighting order. The matter is before the Electrical Committee.

**Whitwell.**—At a recent meeting of the Parish Council the electric light question was discussed, and it was decided to hold a public meeting on the 16th inst. to discuss the possibility of forming a private company, failing which the Council will enlist the help of the District Council.

**Chester-le-Street.**—The Rural District Council have now consented to the application of the Durham Electrical Power Distribution Company, Limited, to the Board of Trade for a provisional order to supply electrical energy for public and private purposes within the Council's district.

**Direct United States Cable Co.**—An interim dividend of 3s. per share, free of tax, being at the rate of 3 per cent. per annum, for the quarter ended Dec. 31, is payable on the 31st inst., and after setting aside £10,000 to reserve fund account the directors carry forward a balance of about £2,876.

**Egypt.**—A contract has been entered into between the Municipality of Mansourah and the Mansourah Electric Supply Company for the establishment of a system of electric light at Mansourah. We understand that the electric lighting of Helouan is to be carried out by the Metropolitan and Cairo-Helouan Railway Company, Limited.

**Middlesbrough.**—A new cable is to be laid at a cost of £340. The engineer in his last monthly report stated that the revenue for the past month had been £1,647, and the works cost £514. The estimated profit for the month, exclusive of interest and redemption, was £1,132. Applications for 514 more lights have been received.

**Bristol.**—A short partial stoppage of the electric light supply was caused on Tuesday by the burning of a cable between the Temple Back works and the generating station at St. Philip's Marsh. There are six cables in use, and it was only during the transference of the current to one of the other five, which was effected in 12 minutes, that any inconvenience was caused.

**Airdrie.**—The Town Council are forwarding to the Board of Trade objections framed by Prof. Kennedy to the draft provisional order now being promoted by the Scottish House-to-House Electricity Company, Limited, for power to transfer the Airdrie electric light order. Mr. Renwick is conferring with a sub-committee of the Lighting Committee with the view of effecting some better arrangement for the electric lighting of the streets.

**Bury.**—The Electricity Committee have profited by the recent fogs. There has also been a considerable increase in the demand for electric current. During the four weeks ended Jan. 1 the number of units sold for lighting and motor purposes was 78.110, an increase of 14,137 units over the four weeks ended Jan. 3, 1904, and during the two weeks ended Jan. 1 they sold 40,107 units, or an increase over the corresponding period a year ago of 11,727.

**Elland.**—Mr. Emmott is to report upon the consumption of coal at the electric station and upon the efficiency of the accumulators. The output from the electricity works has gradually increased from 403 units per week at the beginning of September to 2,447 units in the last week of the year. It is reported that the destructor, which provided sufficient motive power for the engines until recently, is rendered useless for the time being through lack of refuse and sludge.

**Eccles.**—The Town Council, having received a letter from the Local Government Board stating that the Board would be prepared to allow a period of 10 years for the repayment of any loan they might sanction with reference to the purchase by the Corporation of electrical motors to be let out on hire, have decided to apply for sanction to the borrowing of £500 for the purchase by the Corporation of electrical motors. They have also resolved that £50 per annum of the salary of the electrical engineer be charged to the public lighting account, in respect of his superintendence of this department.

**Hammersmith.**—The last report of the Electricity and Lighting Committee states that the premises of 12 additional consumers, representing a maximum of 406 8-c p. lamps, have been connected to the mains, that 11 consumers have been disconnected, and that the present number of consumers taking current from the mains is 1,533. An application from the Postmaster-General for the consent of the Borough Council to the placing of an underground telegraphic line along the east side of the Broadway, from the existing line outside 23, The Broadway, to the Hammersmith Police Station, has been agreed to.

**Plymouth.**—At the last Council meeting Mr. Radford, in moving the adoption of the report of the Electricity and Street-Lighting Committee, said a deputation representing the Amalgamated Society of Engineers had appeared before the committee and complained of the non-employment of *bonâ fide* engine fitters at the electricity works. The committee resolved that the society be informed that the existing arrangements at the electricity works were conducive to the efficient working of the undertaking, and that they saw no reason to interfere, but that if in the future the deputation desired to make any specific complaint, the committee would give it consideration. The report was adopted.

**Golborne.**—During a debate upon the electric light question at the last Urban District Council meeting a letter was read showing that the gas company are willing to withdraw the clause as to the electrolysis and temporary support provided that the Council agree to insert a clause providing for triennial instead of quinquennial revisions of accounts, and with the following as a sub-clause: "There shall not be made against the district rate, or any other rate, for energy used by the undertakers for the street-lighting or any other purpose, a charge at a higher price than that charged to the consumers using energy for similar purposes and for the like hours of supply." It was agreed that the matter should be decided by the Board of Trade.

**St. Marylebone.**—The electric light loan came again before the Council last week, when a letter was read from the solicitor to the

Digitized by Google

London County Council stating that the Council had cancelled its order of July 26, 1904, and had resanctioned the borrowing by the Council of a sum of £435,800, repayable as to £340,405 in 42 years, the first repayment in three years; as to £48,545 within 38 years, and as to £44,850 within 10 years. The Council was prepared to advance £100 000 (on account of the £340,405). £50,000 at once and as to £50,000 at a time convenient to the Council to be repaid with interest at the rate of £3. 15s. per cent. per annum. The Electric Supply Committee advised that the Council should accept the terms proposed.

**Bradford.**—At the last Town Council meeting the Electricity Committee reported that a deputation of the committee had visited London, Dublin, and Newcastle for the purpose of inspecting generating stations and sub-stations on the high-tension alternating three-phase system. The report of the deputation in favour of the adoption of this system in Bradford has been approved; and the committee recommended that the work should be carried out at a cost of £40,876, the town clerk to be authorised to apply for sanction for the borrowing of this money. This was agreed to, as well as the recommendation that a motorcar be purchased at an estimated cost of £325 for the use of the electricity department, the coachbuilding for the car to be done by direct labour at the Thornbury tramcar workshop.

**Worthing.**—At a recent meeting of the Electricity Committee a letter was read from Mr. A. A. Siebold, of the Theatre Royal, stating that he would prefer to continue to take current from the Corporation instead of putting down his own plant, and offering to pay at the rate of 4½d. per unit for the next two years on the understanding that at the expiration of that period the Council would reconsider the matter with a view to a further reduction being then made if found to be practicable. After negotiations the following agreement was arrived at with regard to rates: Over 1,000 up to and including 5,000 units per annum at 6d. per unit, 7½ per cent. discount; over 5,000 up to and including 10,000 units per annum at 6d. per unit, 15 per cent. discount off the whole; if over 10,000 units per annum consumption, the charge to be at the flat rate of 4½d. per unit net.

**West Hartlepool.**—The electrical engineer has been authorised to obtain tenders for an additional 250-kw. set, to be a duplicate of No. 7 set, with the necessary switchboard, panel, etc., and application will be made for sanction to borrow £2,200, the estimated cost of the addition. In his report to the committee the electrical engineer dwelt upon the very urgent necessity of installing additional plant at the electric light station, and said the whole of the plant now installed, with the exception of one single 100-kw. set, had been in use for the last two months, and it was quite to be expected that during January, when the Seaton Carew Ironworks had their 60 b.p. connected, and the Cliff House Foundry were finally connected, that this one single 100-kw. spare set would have to be put on load. There would then be absolutely no spare plant at all. Roughly, the increase during the year had been the equivalent of 100 kw., and he expected the same for the year 1905-6.

**Boilers.**—We learn that the Stirling Boiler Company, Limited, and the Stirling Company of U.S.A. have come to an arrangement whereby litigation which had been pending between the two companies for nearly a year has been satisfactorily settled. The company have acquired all the British and European patents of the American company, and in future all boilers sold in these markets will be of British manufacture. The company are well equipped for dealing with a large volume of trade. They have large works at Motherwell, in the heart of the steelmaking industry of Lanarkshire. We understand that both the American four-drum type and the British five-drum Stirling boiler will be sold in this country. The Stirling boiler is not an experimental boiler, as it has been established for years, and the combined American and British companies will probably be the largest boiler concern in the world. We congratulate these companies on the satisfactory ending of their differences.

**Agencies.**—The Lancashire Electric Power Company, 78, King-street, Manchester, having decided to open a hire-purchase branch in the Lancashire district, have appointed Mr. Philip C. Pope, lately with the British Westinghouse Electric and Manufacturing Company, of Trafford Park, engineer to the hire-purchase and development department. We are informed that there seems to be very good prospects for a considerable amount of hire-purchase business in connection with the supply of power from the mains in this district. The Phœnix Dynamo Manufacturing Company, Limited, of Thornbury Works, Bradford, have opened an office at 17, Victoria-street, Westminster, in charge of Mr. E. W. T. Ward, who has recently joined their staff as London representative. Their telegraphic address is "Phedyna, London," and their telephone number 1,061 Victoria. Messrs. Balcke and Co., condenser specialists, 27, Clement's-lane, E.C., have opened a new branch office at Imperial-chambers, Albert-street, Derby. Messrs. Andrew Brown and Co., 110, Cannon-street, E.C., have been appointed the London and district agents for Messrs. Penman and Co., boilermakers, Caledonia Ironworks, Glasgow.

**Cardiff.**—The subscriptions received in response to an appeal made to equip and furnish the infirmary building with the necessary electrical appliances, and to furnish it ready for use, amount to £438, in addition to £22 collected for an electric magnet. The building, which, according to the *South Wales News*, is one of the most perfect in the provinces, has been built at a cost of £2,000, and this amount has been mainly contributed by an anonymous lady. It has practically stood idle because funds were not forthcoming to equip it, but the generous response to the appeal has removed this difficulty, and the building will be started on its career of usefulness in the cause of humanity and science on Jan. 26. In brief, the work to be undertaken in this most important department of the infirmary is as follows: examination and treatment of patients by means of the electric appliances; photographing fractures, dislocations, and diseases of bones; localisation of foreign bodies; examination of chest, including detection of phthisis in early stages, heart, and kidney. Also the treatment of lupus and certain form of cancer (rodent ulcer), and various skin and other diseases. The electric magnet will be used for removing particles of steel from the eye, thereby in many cases saving the eye. The pavilion will be formally opened on the 26th inst. by Sir W. H. Preece, and all who are interested in the work of the infirmary are cordially invited to attend.

**South Africa.**—The large power station which supplies the current to light Kimberley has been completed, while the supply to the township of Beaconsfield was turned on in October. We understand that the Port Elizabeth Municipality have now decided to advertise for tenders in connection with the lighting and power scheme drafted by Mr. R. Pape, the borough electrical engineer. The electrical engineer of Greytown, near Durban, has notified the authorities of the necessity for doubling the station equipment at an early date. With regard to the electric light scheme for Klerksdorp, the *British and South African Export Gazette* says that the Klerksdorp Town Council recently had under consideration a motion relating to the engagement of a competent engineer to report on a scheme for lighting the town by electricity. The cost of an expert, it was considered, would be considerable, but the advantage of his advice was recognised. In the upshot, the matter was referred back for enquiries to be made as to the probable cost. The town has a population of under 5,000, but is the centre of an important gold, coal, and diamond district which ensures for it great expansion at an early date. The township of Gwelo, Rhodesia, affords an opportunity for a private electric lighting company. The Town Council of Heidelberg, Transvaal, are about appealing to the ratepayers for sanction to a loan of £100,000 for a multiplicity of public works, including public and private electric lighting. The Kingwilliamstown Council are about to acquire the King Electric Lighting Company's assets, and will extend the system.

**Wilmslow.**—At their last meeting the District Council considered the report of the sub-committee on street-lighting, and adopted a recommendation to replace gas lighting by electricity. During the course of the meeting the sub-committee reported on the various tests made with gas and electric light, from which we learn that the contract with the gas company which was in force when the committee was appointed stated that the period of lighting commenced on Aug. 18 and ended on May 14, both dates inclusive, the lamps to be lighted at dusk, and the extinguishment to commence half an hour before midnight, except for six nights during each moon, when such lamps shall not be required to be lighted. The committee approached the Alderley and Wilmslow Electric Supply Company, Limited, of which Mr. Cuthbert W. Bentley is the resident engineer and secretary, with a view to ascertain whether they would be prepared to undertake the electric lighting of the district. The company were willing to do so on condition that if their scheme was accepted a contract for five years would be given to them. The committee subsequently submitted to the company a contract identical to that in force with the gas company, with the exception that for the clause which said that the lamps shall be lighted at dusk, and which was considered indefinite and liable to misunderstanding, the following was substituted; "The lamps must all be lighted within one hour after sunset, and extinguishing be commenced before 11.30." Comparative tests were then made, including a reading test, which consisted of reading the same printed circular at all the lamps tested. Each lamp was tested alternately, the other competing lamps being turned out, and the following are the results given: gas new flat-flame burner, seven yards away; electric 40 c.p., 17 yards away; gas incandescent (new mantle on main road), 15 yards away) electric 70 c.p., 23 yards away; electric 100 c.p. (for Bank-square), 30 yards away. The comparisons made have been between the existing lamps and those they would replace, and the increase in light over the present system would be very great indeed. The recommendation of the committee (which, as above stated, was adopted) read as follows: "That we substitute our present system of street-lighting by gas for that by electricity, and that we place the following lamps: 170 lamps of 40 c.p. on roads other than the main roads at 28s. per lamp, £238; 39 lamps of 70 c.p. from Alderley to Manchester-road at 38s. per lamp, £74. 2s.; one lamp of 140 c.p., Bank-square, to burn from sunset to daylight, at 123s., £6. 3s.; one lamp of 70 c.p., top of Manchester-road, to burn one hour after sunset to daylight, at 70s., £3. 10s.—total, £321. 15s. At present we pay 209 lamps at 32s. 6d. per lamp, £339. 12s. 6d.; two large lamps, £11; one lamp in Moor-lane, extra gas, 15s. 6d.—total, £351. 8s., or a saving of £29. 13s." We understand that the new installation will be ready for the commencement of the next lighting season, Aug. 18, 1905, and also that Edmundson's Electricity Corporation will act as securities for the proper carrying out of the contract. A careful perusal of the committee's report shows that the electric light company undoubtedly beat the gas company at every turn during the trial. The lamps they propose installing are the ¼ and ½ ampere Nernst. The ¼-ampere will be installed in place of the ordinary flat-flame gas-burner, and the ½-ampere replaces the incandescent mantle. The company hope shortly to commence laying the mains for street-lighting and private supply throughout Wilmslow. The total length of these will be about 12 miles, and about three miles of feeders.

**St. Pancras.**—The following report by Mr. Sydney W. Baynes was adopted by the Council on Wednesday: "Having regard to the low charges we have established for motive power in order to promote our day load, and bearing in mind the many advantages of a supply of electricity during the daytime for all purposes to the many commercial industries of this borough, I have studied the problem very thoroughly with a view to placing before you some recommendation which shall popularise electricity in this respect." In order that the committee might be in full possession of the existing state of affairs concerning the various loads carried by the generating plant throughout the 24 hours, a diagram accompanied the report showing a curve in which the vertical figures gave the load in kilowatts, or units per hour, being supplied, and the horizontal figures showed each hour in the day

Digitized by Google

throughout the 24. The curve represented the highest load dealt with in November last, which occurred on the 16th. It showed that for 16 hours out of the 24 the current passing from the station only averaged some 600 units per hour, whilst the maximum call upon the station, shown by the greatest height of curve reached a rate of 3,200 units per hour, and as a consequence the committee were compelled to provide and maintain generating machinery and cables capable of supplying this higher rate. "The present rates for electricity are based on this condition of affairs and naturally cover all charges for interest and sinking fund. It is obvious from a study of the diagram that were it possible to increase the day load (shown by the straggling horizontal line on the diagram, between 12.30 midnight and 4.30 the following afternoon we could do so without involving either any additional capital outlay on extra generating plant and mains or charge to revenue in manipulating the existing plant, except the following charges per unit which I have obtained from our last year's balance-sheet: coal, ·61d.; oil, waste, etc., ·07d.; repairs and maintenance, say ·15d.—making a total cost of ·83d. per unit sold. I have taken repairs and maintenance at an estimate of one-half the actual figure because the actual wear and tear is only due to the running of the machinery; there is no depreciation brought about on our mains, whether they are doing full duty throughout the 24 hours or not, and consequently no charges for extra repairs on the mains will occur. With regard to the wages at the generating station, these are in no way increased by the day load, and consequently do not enter into these costs. The above figures give us a total cost of ·83d. per unit for generating electricity if current be taken from us between the hours of 12 midnight and 4·30 the following afternoon. The object of the foregoing is to show that any current sold during the daytime up to the time of peak load will cost us only ·83d. per unit. I propose, therefore: (1) That we should establish a system of day load supply for lighting purposes at the same rate as motive power, provided that the supply is not taken from us between the hours of 4.30 in the afternoon and 8.30 p.m., these being the hours approximately of peak load; any current drawn from our mains during the hours of peak load to be charged at the rate of 6d. per unit. (2) That day load shall only be available to customers who will guarantee to burn during the business hours of the day not less than 10 lamps in their cellars or at the back of their shops as the case may be. (3) Charges for extra meters and switching-over gear to be borne by every consumer availing himself of these specially low rates. (4) All customers receiving current under these special rates will be liable to be cut off at any time that circumstances may necessitate in a similar way to which we reserve the right in giving the special low motor rates now in force. (I need scarcely point out to the committee that this is an emergency that has never yet arisen, but we find it advisable to reserve this right in the case of day loads at special rates, and I see no objection to imposing it in this case.) Again referring to the diagram and tracing the vertical line at 4.30 p.m. we see that the load on the station has begun to rise considerably, and at 8.30 p.m. it has again fallen, so that our plant may be considered fully monopolised for lighting load between 4.30 and 8.30 o'clock in the evening. There are a few consumers who close their premises as early as 7 o'clock in the evening throughout the year. I have carefully investigated the number of hours such a consumer would draw from our supply during the hours of peak load (between 4.30 and 7 p.m.) in order to ascertain, assuming these low rates are in operation, whether they would prove profitable to the undertaking at the proposed new rates; I find their load between 4.30 and 7 p.m. will average 1¼ hours per day throughout the year, and this will be at the higher rate of charge proposed—viz., 6d. per unit. By reference to the diagram of costs prepared on our last balance sheet, I find that the total cost to us at 1¼ hours per day, including all capital charges, etc., is very slightly over 6d. per unit, so that although we should not make any profit from the peak load supply to such a consumer, the day load drawn at the lower rate at 1d. per unit would yield a profit of ·17d. per unit, the cost of generating the day load supply being ·83d. per unit. Should the committee approve of this proposition for day load charges it would be possible for such firms as Shoolbred's, Maple's, Oetzmann's, and other large firms to provide a set of secondary batteries which could be charged during the hours of day load from our supply at the low rate, and these batteries could be utilised to maintain their lighting during the peak load. Such a customer would be a profitable one to our undertaking even at the low rate of 1d. per unit, because we should be in the position of being able to supply him with current without involving any capital charges whatever. I feel confident with such a low rate available that there are a number of ratepayers possessing their own generating plant who would find it a distinct advantage to draw current from us during the daytime rather than generate their own, and taking it on the whole I am sure that we should not only popularise the use of electricity, but that we should find it a distinct advantage financially to the undertaking in obtaining additional day load, which, as I have shown, would cost a very low rate to provide. There is a further possibility of long load in the development of electric signs, and again referring to the diagram, we see that even at 7.30 p.m. our load has commenced to fall, and since we could never contemplate a very large load due to these signs, I do not consider there would be any risk incurred if we allow these electric signs to go on at the 1d. rate between the hours of 7.30 in the evening and 4.30 the following afternoon: should it be found desirable to burn these electric signs during the prohibited hours, of course customers would be at liberty to do so through a separate meter at 6d. per unit. It may occur to some members of the committee that these suggestions do not wholly concur with the recommendations in the earlier part of this report, inasmuch as I have shortened the hours of prohibited load. I have done so to meet the views somewhat of customers having electric signs who have pointed out to me that unless they are in a position to display them at a fairly early hour in the evening, the advertisement obtained by catching the theatre traffic would be lost, and on making a study of our peak load diagram we see that it would be possible to strain a point in this case without it being a disadvantage to the undertaking, bearing in mind that the demand on our plant for electric signs can only become a small percentage of the total, and there is therefore little fear of their providing a peak load which would exceed that obtained by the lighting. In considering this report, I feel confident the committee will deal with the matter on broad lines, bearing in mind that the installation which we control is the property of the ratepayers generally, and this being so, it is desirable that they should be able to avail themselves of its use in every conceivable way, provided it does not increase the cost of operating the machinery to the detriment of the undertaking." The committee recommended the adoption of a system of day load supply for lighting purposes at the same rate as motive power—namely, 1d. per unit—under the following conditions: (1) the supply at this special rate is not to be used between the hours of 4.30 in the afternoon and 8 30 p.m., these being the hours approximately of peak load, any current drawn from the mains during these hours to be charged at the rate of 6d. per unit; (2) charges for all extra meters and switching-over gear, necessary to register the supply under the foregoing conditions, to be borne by every consumer availing himself of these specially low rates; (3) all customers receiving current under these special rates will be liable to be cut off at any time that circumstances may necessitate in a similar way to which is reserved the right in giving the special low motor rates now in force. In the thoroughfares where it is anticipated it will be some time before electric mains will be laid, it has been decided to substitute 500 incandescent gas lamps for the existing open-flame burners. The recommendations were agreed to.

## PROVISIONAL PATENTS, 1904.

DEC. 27.

**28329. An improvement in or connected with the working of telephonic systems.** Robert Lambert Murray and Frederick Thomas Jackson, 9, Regent-street, London. (Complete specification.)

**28336. Improvements in brush-holders for dynamo-electric machines and other uses.** Veritys, Limited, and Daniel Evan Rogers, 11, Burlington-chambers, New-street, Birmingham.

**28345. Improvements in regulating gear for use in connection with train-lighting and similar dynamos.** Charles Dixon Charlesworth and John Robert Charlesworth, 24, Temple-row, Birmingham.

**28349. Improvements in the generation and distribution of electricity.** Walter Dixon, 121, West George-street, Glasgow. (Complete specification.)

**28350. A new or improved attachment or appliance for use in connection with suspended electric lamps.** Edgar Augustus Joseph Hooper, 24, Temple-row, Birmingham. (Complete specification.)

**28369. Improvements in electric switches.** George Harrison, 11, Southampton-buildings, Chancery-lane, London. (Monroe Guett, United States.) (Complete specification.)

**28370. Improvements in electric switches.** George Harrison, 11, Southampton-buildings, Chancery-lane, London. (Monroe Guett, United States.) (Complete specification.)

**28375. Electric bipolar plates accumulator.** Gustavus Martin Zingel, 132, Hanley-road, London.

**28393. Improvements in or relating to electric current governors.** Alfred Julius Boult, 111, Hatton-garden, London. (Walter Joseph Richards, United States.) (Complete specification.)

**28409. Electric arc lamp.** Wallace Fairweather, 65, Chancery-lane, London. (The Marquette Electric Company, United States.) (Complete specification.)

**28416. Appliance for the commutation of current in armatures of dynamos.** Engelbert Arnold and Jens Lassen la Cour, 34, Castle-street, Liverpool. (Complete specification.)

**28453. Improved continuous-current electric motor.** Soc. Anon. pour le Travail Electrique des Métaux, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 10, 1904, being date of application in France.) (Complete specification.)

**28455. Improvements in central telephone station installations.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges., Germany.) (Complete specification.)

**28458. Incandescent electric lamp.** Franklin Wise Howorth, 46, Lincoln's-inn-fields, London. (John Henry Guest and Charles Isaac Hills, United States.)

**28467. Improvements in or relating to electric incandescence lamps.** William Phillips Thompson, 322, High Holborn, London. (Deutsche Gasglühlicht Act.-Ges. (Auer Ges.), Germany. (Complete specification.)

**28468. Improvements in systems of electrical conductors.** Béla Gáti, 322, High Holborn, London. (Complete specification.)

**28471. Combined starting and braking device for electric motors.** Arthur Hultqvist, 322, High Holborn, London. (Complete specification.)

**28495. Improvements in or relating to automatic electric switches.** Anton Firley, 18, Buckingham-street, Strand, London.

Digitized by Google

DEC. 28.

**28522. Improvements in electric signalling on railways.** William John Mackenzie, 100, Wellington-street, Glasgow.

**28525. Improvements in trolley standards for electric tramcars and the like.** Montague Brown Mountain and Godfrey Marsden Gibson, 55, Market-street, Manchester.

**28546. Improvements in protected or armour-clad switch-fuses.** Herbert Henry Berry, Uplands House, Chase Ridings, Enfield.

**28554. Improvements in or relating to thermo-electric couples.** Alfred Julius Boult, 111, Hatton-garden, London. (William Hoskins, United States.) (Complete specification.)

**28601. Improvements in apparatus for electro-deposition of metals.** Willis Rinaldo King, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**28608. Improvements in and relating to "electric candle" lamps.** Charles Clare Regnart and the Hunter Electric Candle Lamp Company, Limited, 29, Anson-road, Cricklewood, London. (Complete specification.)

**28628. Improvements in or relating to arc lamps.** Joseph Rosemeyer, 322, High Holborn, London. (Complete specification.)

**28629. Improvements relating to drop-signals or annunciators for central telephone stations and so forth.** Isidore Bernard Birnbaum, 322, High Holborn, London. (Complete specification.)

DEC. 29.

**28677. Improved safety device for electric railways.** Frederick Owen, 6, Lord-street, Liverpool.

**28678. Improvements in or applicable to cranes and other lifting machinery driven by electric motors.** Frank William Reed and Craven Bros., Limited, 70, Deansgate, Manchester.

**28687. Improvements in means or apparatus for automatically starting, controlling, and stopping single or multi-phase alternating-current electric motors.** Oswald Carr and John Charters Birch, 50, Wellington-street, Leeds.

**28689. Globe or shade carrier for gasfittings, oil-lamps, electric light fittings, and the like.** Thomas William Maddox, 173, Bevington-road, Aston, Birmingham.

**28717. Improved operating gear for groups of electrical switches and rheostats.** Wolf Defries, 60, Queen Victoria-street, London.

**28722. Improvements in or relating to electric incandescent lighting devices.** Carl Schwabe, 6, Lord-street, Liverpool. (Complete specification.)

**28723. Improvements in electric incandescent lighting devices for shop windows, showcases, and the like.** Carl Schwabe, 6, Lord-street, Liverpool. (Complete specification.)

**28724. Improvements in electric incandescent lighting devices for billiard tables, exhibition tables, sale counters, and the like.** Carl Schwabe, 6, Lord-street, Liverpool. (Complete specification.)

**28741. Improvements in and relating to electric ignition devices for internal-combustion engines.** William Henry Astell, 70, Chancery-lane, London.

**28749. Improvements in or relating to telephones for the use more particularly of divers.** Edwin Charles Lacey and James Holman, 53, Chancery-lane, London.

**28787. Improvements in electrical switches.** George Benjamin Stern and Albert Cecil Greene, 14, Coleman-street, London.

**28791. Improvements in electric current distributors for luminous letters.** L. Snoeck, 46, Lincoln's-inn-fields, London.

**28804. Improvements in and relating to insulators for high-voltage electric lines.** Società Ceramica Richard-Ginori, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 22, 1904, being date of application in Italy.) (Complete specification.)

**28824. Improvements in electric igniting arrangements for internal-combustion engines.** Louis Renault, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Feb. 2, 1904, being date of application in France.) (Complete specification.)

**28826. Improvements in or connected with space telegraphy.** John Stone Stone, Norfolk House, Norfolk-street, Strand. (Date applied for under Patents Act, 1901, Feb. 13, 1904, being date of application in United States.) (Complete specification.)

**28827. Improvements in or connected with bolometers and space telegraphy.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 15, 1904, being date of application in United States.) (Complete specification.)

DEC. 30.

**28845. Improvements in anti-vibration electric couplings.** Robert William Bill and Sidney Bill, 9, Headingley-road, Handsworth.

**28852. An improved conduit for containing electric cables and wires, and other wires, tubes, pipes, and the like.** Walter Hepworth-Collins, 17, Nicholas-street, Manchester. (Complete specification.)

**28858. An improved electric switch and circuit breaker.** John Arthur Hirst and Percy Smith Brook, Northgate Electrical Works, Chester.

**28860. A self-acting motor-starting rheostat.** John Arthur Hirst and Percy Smith Brook, Northgate Electrical Works, Chester.

**28875. Plug adapter for electric lamps.** William Frank Simmonds, 4, Newton-street, Holborn, London. (Complete specification.)

**28889. Improvements in or relating to electric control circuits with heat indicators.** Martin Arnold Abrahamson, 322, High Holborn, London.

**28895. Electric lamp for ovens.** William Emerson George Read, 486, Edgware-road, London.

**28899. Improvements in electric bell-pushes.** William Walker, jun., 7, Staple-inn, London.

**28962. Improvements in galvanometers.** Jules Richard, 11, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 3, 1904, being date of application in France.) (Complete specification.)

**28968. Improvements in series commutator motors for single-phase alternating current.** The Maschinenfabrik Oerlikon, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Feb. 29, 1904, being date of application in Switzerland.) (Complete specification.)

**29001. Improvements in or relating to electric railway conduit systems.** Joseph van Aerschot, 111, Hatton-garden, London. (Complete specification.)

**29004. Improvements in or relating to electric railways and tramways.** Charles Mackintosh, 111, Hatton-garden, London.

**29014. Improvements in electric switches.** Robert Longden, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**29015. Improvements relating to the automatic control of overloads in electric circuits.** Siemens Bros. and Co., Limited, and Percy Gilbert Ledger, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**29054. Improvements in electric incandescent lighting devices for pictures, music desks, writing desks, pianofortes, and the like.** Carl Schwabe, 6, Lord-street, Liverpool. (Complete specification.)

**29057. Improvements in electric insulation.** Max Meirowsky, 6, Lord-street, Liverpool.

**29058. Improvements in terminals for electric conductors.** Louis Renault, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, May 2, 1904, being date of application in France.) (Complete specification.)

**29059. Improvements in electric ignition plugs for internal-combustion engines.** Louis Renault, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, May 2, 1904, being date of application in France.) (Complete specification.)

**29063. Improvements in or connected with insulators of overhead electric conductors.** Emile Giraud, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 14, 1904, being date of application in France.) (Complete specification.)

**29064. Improvements in safety devices for overhead electric conductors.** Emile Giraud, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, April 14, 1904, being date of application in France.) (Complete specification.)

**29074. Improvements in metal reflectors for use with electric lanterns.** Jean Alexander Rey, 24, Southampton-buildings, Chancery-lane, London.

**29079. Improvements in electric current measuring and recording apparatus.** George Gatton Melhuish Hardingham, Clun House, Surrey-street, Strand, London. (Vittorio Arcioni, Italy.)

**29092. Improvements in or relating to electrically-propelled automobile vehicles.** Pierre Marical, 18, Buckingham-street, Strand, London.

**29107. Improvements in telephones for diving and like purposes.** Robert Henry Davis and Alfred Graham, 4, South-street, Finsbury, London.

**29125. Improvements relating to switching devices for electric lamps, especially adapted for use in "flash" advertising.** Leonard Kingwill Job, 322, High Holborn, London.

**29129. Improvements in and relating to electromagnetic separators.** William Blackmore, 18, Southampton-buildings, Chancery-lane, London.

**29138. Improvements in electric dry batteries.** Charles Aubrey Day, 321, High Holborn, London. (Empire State Dry Battery Company, United States.)

**29142. Improvements in space telegraphy.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 23, 1904, being date of application in United States.) (Complete specification.)

**29143. Improvements in or connected with space telegraphic receiving systems.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Feb. 23, 1904, being date of application in United States.) (Complete specification.)

**29144. Improvements in space telegraph systems.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 11, 1904, being date of application in United States.) (Complete specification.

Digitized by Google

**29145. Improvements in space telegraphy.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, April 11, 1904, being date of application in United States.) (Complete specification.)

**29146. A new or improved support for use in space telegraphy.** John Stone Stone, Norfolk House, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 3, 1904, being date of application in United States.) (Complete specificatton.)

**29165. Improvements in electric dry batteries.** Herbert William Butler, 47, Lincoln's-inn-fields, London.

DEC. 31.

**29180. An improved magnetic compass.** John Fisher Le Page, 8, King-street, Manchester.

**29187. Improvements in electric igniters for explosion motors.** Henri Guillou, 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 2, 1904, being date of application in France.) (Complete specification).

**29233. Improvements in or connected with low-tension electric ignition devices for internal-combustion motors.** Albion Motorcar Company, Limited, and Thomas Blackwood Murray, 121, West George-street, Glasgow. (Complete specification.)

**29259. Charging plug and leads for charging an accumulator from the lampholder on any direct-current electric lighting circuit.** Ernest Philip Melancthon Eldridge, 47, Gloucester-street, London.

**29281. Improvements in apparatus for opening and closing electric circuits at predetermined times.** John Gunning, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**29307. Improvements in or relating to switches for electric incandescent lamps.** Armand Frey, 111, Hatton-garden, London. (Complete specification.)

**29308. Improvements in or relating to the detection and recording of electrical impulses or oscillations and apparatus therefor.** George Finlay Anderson, 111, Hatton-garden, London.

**29310. Improvements in or relating to electrical dumb-bells and similar appliances for physical exercises.** Alfred Loebl, 111, Hatton-garden, London. (Complete specification.)

**29337. Method of and means for the protection of electrical apparatus branched on circuits which are traversed (accidentally or otherwise) by currents of high frequency.** Georges Eugène Gaiffe, 53, Chancery-lane, London.

**29343. Improvements in or connected with electrical gas-igniting and extinguishing apparatus.** Henry Langdon Down and Douglas Herbert Wiseman, 115, Cannon-street, London.

**29345. Improvements in or connected with electrical gas-igniting and extinguishing apparatus.** Henry Langdon Down and Douglas Herbert Wiseman, 115, Cannon-street, London.

**29346. Improvements in or connected with electrical gas-igniting and extinguishing apparatus.** Henry Langdon Down and Douglas Herbert Wiseman, 115, Cannon-street, London.

**29347. An improved electric transformer.** Gustav Stern, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published Jan. 19, 1905.*

1903.

**28062. Electric chain welding machines.** Helberger.

1904.

**716. Control and propulsion of vehicles propelled by electric motors.** Raworth.

**2152. Electrolytic cells.** Raschen, Clayton, and United Alkali Company, Limited.

**4676. Insulators for the conductors of electric railways.** Henry Percy Bradford, Frank Dietrich Ward, and Harry Crampton Furniss.

**4770. Automatic regulators for alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

## NOTES.

**Personal.**—The St. Petersburg Academy of Sciences has elected Sir Norman Lockyer a corresponding member. Dr. D. H. Scott has been re-elected president of the Royal Microscopical Society, with Mr. G. C. Karop, Sir Ford North, Mr. H. G. Plimmer, and Dr. H. Woodward as vice-presidents.

**Islington Electrical Exhibition.**—We learn that the electrical exhibition which the Islington Borough Council proposed to hold in February or March, as announced in our issue of the 6th inst., has been postponed until October or November. In the meantime the borough electrical engineer, Mr. Albert Gay, will be glad to receive any applications for space or for advertisements in the catalogue.

**Errata.**—We regret that in publishing the article last week on "Electricity in India and Burma" we made a mistake in the author's name. It should be Mr. E. C. Deefholts, and not "Deepholt." In the article itself "Sibpur" is mis-spelt Silepur. We regret this error in the name of the place, which is noted as the home of the civil engineering college which is doing such good work in the technical education of engineers in India.

**Electro-Harmonic Society.**—This society will hold its first concert of the present year to-night in the King's Hall of the Holborn Restaurant, commencing at 8 o'clock. The vocal artists will be Messrs. Jas. Davis and Harry Dearth, while the instrumental music will be in the familiar hands of Messrs. Izard and Gatehouse, with Mr. B. C. Goodhead. A delightful programme will be completed by miscellaneous features, contributed by Messrs. J. Warren, C. Gellett, and G. Robins.

**Engineering Standards Committee.**—We have received this committee's twelfth report, which deals with the standard specification for Portland cement. The sub-committee appointed to consider this branch held a dozen meetings in all. The report embraces sections on quality and preparation, sampling, specific gravity, chemical composition, mode of gauging, tests, soundness, etc. It is supplemented by diagrams which help to make the Standards Committee's methods invariable.

**Wireless Telegraphy.** — It is announced that Marconi's Wireless Telegraph Company, Limited, has entered into an agreement with the Oceanic Steam Navigation Company, Limited (the White Star Line) for the equipment of six of the White Star Line vessels—the "Oceanic," "Celtic," "Baltic," "Cedric," "Majestic," and "Teutonic"—with Marconi wireless apparatus. It is hoped that the first of these liners—the "Oceanic"—may be equipped in readiness for her voyage from Liverpool on Feb. 1. The remainder of the vessels will be fitted at short intervals after that date. When the boats mentioned have been equipped under the agreement referred to, practically all the Atlantic liners of the first-class shipping companies will be carrying Marconi apparatus.

**Novel Danger Signal.**—During a great gale in February, 1903, a mail train was blown over on Levens Viaduct, on the Furness line, and almost fell into the sea. The Furness Company, in order to prevent similar accidents, have now erected an ingenious instrument which will automatically warn the signalmen on duty when there is unusual wind pressure of sufficient force to be dangerous to trains crossing the viaduct. The apparatus consists of a combined wind pressure gauge and recorder, and is connected with an electrical device by means of which bells are set in motion at distant signal-cabins. These bells will continue to ring so long as the velocity of the wind on the viaduct is dangerous to passing trains, consequently all traffic will be stopped until the wind pressure falls below the point of danger.

**"Tube" Construction.**—The London County Council and the promoters of the Great Northern, Brompton, and Piccadilly Railway are at issue over the completion of the tube railways in the Metropolis, owing to the London Council having refused sanction for continuation of the work except under certain conditions. The Council's case is that under the Great Northern and Strand Company's Act of 1899, the company were restrained from working below the new Kingsway pending the completion of the Council's work thereon. There is also a clause of the same character in the Improvements Bill promoted by the Council in 1899. The Kingsway improvement is not yet completed, but the company require permission to waive the stipulation in the Bill, and at once to continue their work The Council are prepared to consent to this, but consider the public interest requires that some compensation shall be given. So far the company have declined to fall in with this view, with the result that a deadlock has occurred. The delay on the part of the Council in the completion of Kingsway seems a poor ground on which to base a claim for compensation.

**Municipalisation and Private Enterprise.**—A conference of London borough councils was held last week at the Shoreditch Town Hall to consider a scheme of combined municipal opposition to the companies promoting Bills in the next session of Parliament for the purpose of supplying electricity in competition with borough councils. The Mayor of Shoreditch presided, and representatives from 21 councils attended. It was resolved to appoint an executive committee to conduct the joint opposition. A proposal was then made by the Town Clerk of Shoreditch, that the committee should consider the advisability of formulating a municipal scheme for a large generating station or stations to supply electricity in bulk to the boroughs. His reason was that this would enable the councils to fight the companies on their own ground, and give a remarkably cheap supply of electrical energy. This proposal, however, met with a somewhat hostile reception, delegates from Poplar, Woolwich, and elsewhere contending that the present municipal electric generating stations in London were sufficiently large for the needs of the respective boroughs, and that the companies could be competed with quite successfully, if necessary, under present conditions. The resolution was consequently withdrawn.

**The Institution.** — At last week's meeting an impressive list of donations to the library was announced; in fact, it seemed as though Mr. Lloyd was going on till Doomsday, but at last he worked his way through to the end of the alphabet. The President expressed a hope that this good example would be followed by many more. In the course of the discussion on Mr. Adams's paper, "The Combination of Dust Destructors and Electricity Works Economically Considered," Mr. G. Watson deprecated the attitude of certain members who had adopted a somewhat adverse view of this system, remarking that there seemed to be a tendency to divide the Institution into two parties—viz, the enthusiasts, and those who threw cold water on enterprising projects. After Mr. Adams's reply, the President made a semi-humorous allusion to this subject, stating that he thought such conduct on the part of members ought to be encouraged, because they would then keep each other in order "just as the Conservatives and Liberals *used* to do"! The arrangements for the next three meetings are

Digitized by Google

as follows: Jan. 26, discussion on Messrs. Booth and Kershaw's paper, "Fuel Economy in Steam Power Plants"; Feb. 9, Mr. G. L. Addenbrooke will read a paper on "The Value of Overhead Mains for Electric Distribution in the United Kingdom"; and Feb. 23, Mr. Donald Murray will read a paper on "Setting Type by Telegraphy."

**Cape-to-Cairo Telegraph.**—The Cape-to-Cairo telegraph has reached Udjidji, the capital and chief town of German East Africa, on the eastern shore of Lake Tanganyika. For the moment construction work is suspended while the route northwards is carefully surveyed and the sections of the line that have been erected are got into thorough working order. From the commercial point of view, the line is quite realising, if not exceeding, the expectations that were formed concerning it. When the work of construction is recommenced the route will probably be along the eastern shore of the Victoria Nyanza, and will then strike due north to the town of Rosares, which is the southernmost point of the Soudanese telegraph system. A junction will be effected here between the two lines, and the scheme for a Cape-to-Cairo telegraph will then be an accomplished fact. The engineers of the line are, however, faced with a difficulty in their preparations for carrying it forward from Udjidji, inasmuch as the country for a distance of nearly 100 miles through which the line would have to pass is very swampy, and quite unfit for the erection of a telegraph wire. It was at first thought that a wide detour would have to be made at this point in order to escape this region, but latterly other counsels have prevailed, and a more enterprising expedient is likely to be tried—the installation of the Marconi system of wireless telegraphy in order to bridge over this inhospitable belt of country. Owing to the reduced speed of signalling we shall be surprised if the wireless link is more than a temporary one.

**Rubber Cultivation.**—The report lately issued by Mr. W. H. Johnston, Director of Agriculture for the Gold Coast, shows how disastrous has been the ruthless tapping of rubber-producing trees by the natives of that part of Africa. The industry exported goods to the value of £555,731 five years ago, but in 1903 the figure had fallen to £196,500. Practically all the rubber trees from the coast to more than a week's journey inland have been exterminated, and the report devotes consideration to the best method of replanting the land so as to give a return on the expenditure initially incurred at as early a date as possible, and at the same time to yield the largest percentage of good rubber. Various objections attach to the Castilloa elastica, the Funtumia elastica, and the Glyphodes ocellata. Mr. Johnston, in conjunction with Mr. C. W. Smythe, a botanical expert, therefore recommends the Hevea brasiliensis, which, since its introduction into the colony, has been remarkably free from insect and fungus pests. The heavy rainfall and the rich soil are both favourable to this variety. As an example, four trees, 10 years old, tapped for the first time in 1903, yielded 67oz. of dry rubber without showing signs of having suffered in the slightest degree. It appears that unless Europeans take up the industry in earnest, it will speedily become extinct on the Gold Coast, as, having derived all the available gain from the plants, the natives manifest complete indifference, and will not trouble to cultivate plants offered them gratis. With the growing dearth of rubber, it would be unfortunate if such suitable territory were allowed to continue in a barren state.

**The Telephone Situation.**—Under the heading of "Preparing for Amalgamation," the *Daily News* indulges in a forecast of the future relations between the Post Office and the National Telephone Company. We give the gist of our contemporary's statement, so that readers may decide for themselves whether they belong to the category of "intelligent anticipations of events." A representative of that paper ascertained that "wholesale alterations have taken place in the company's system since Jan. 1, which would seem to indicate that the purchase agreement has been signed, and is only awaiting ratification by Parliament." The article proceeds to state that very extensive changes have been made in the company's organisation, which will render amalgamation with the Post Office much more easy when the time comes. Before Jan. 1 the London area was divided into six districts, each of which was in charge of a local manager, with a staff of clerks and other employés. The company has adopted the American system of telephone organisation, the watchword being centralisation of the strictest kind. The new exchange which will shortly be opened at London-wall is, states the *Daily News*, regarded as a decided step towards amalgamation with the Government system. Like the Post Office service, several central battery exchanges have been installed. The Post Office has adopted a similar system, which is looked upon as the one that will ultimately prevail throughout the kingdom. This exchange will contain about 3,500 direct telephone lines for subscribers, which will be worked by 90 operators, and several new electrical inventions which have been adopted by the Post Office will be used.

**American Patent Examination.**—We notice in the *Electrical Review* of New York the following description of a patent issued as recently as Dec. 13 last for an improved magnet coil. The interest in the patent to us lies in the fact that it describes a method of construction which has been used for many years in dynamo work, and is now the common practice among electrical manufacturers, in the United Kingdom at any rate. A great deal is made of the advantage of a search for prior patents, and we are quite sure that if the examiner who passed this patent had been referred to manufacturers of dynamos, the latter would promptly have recognised an old friend. As it is, the patent has been issued, and, were it not for the universal use of this method of winding, we presume that the owners of the original patent would attempt to claim royalties for the same. Apparently, the parties concerned imagine the patent to be valid, as the Keystone Electric and Manufacturing Company, of Pittsburg, have obtained an assignment of same from Mr. A. Schweitzer, the grantee. The abstract of the patent, as appearing in our contemporary, reads as follows: "The invention relates to improvements in electromagnet coils, such as solenoids, etc. The object is to provide a coil for these purposes which occupies a smaller space than coils as ordinarily wound, and which, nevertheless, has a larger current-carrying capacity and produces less heat and offers less resistance proportionately. Another object is to produce a coil which can be insulated in such a manner as to prevent the same being burned out or short-circuited, and which is simple, durable, and strong. The invention consists of a coil having a spiral conductor composed of a flat strip wound edgewise to form a plurality of convolutions, the flat faces of which lie in substantially parallel planes and are separated by discs of mica or other suitable insulating material slid in from one edge to the centre and arranged between the several convolutions of the coil."

**Patent Law Reform.**—The President of the Board of Trade has issued a report with reference to the resolution adopted, at the instance of the Manchester Chamber of Commerce, by the Association of Chambers of Commerce, at the recent meeting in Manchester, urging on the Board the necessity for a further amendment of the patent laws so as to secure the forfeiture of all British patents for inventions and registered industrial designs which are

Digitized by Google

worked or made abroad, but not within the United Kingdom. The Board of Trade points out that the resolution is apparently at variance with Article 2 of the additional Act of Dec. 14, 1900, modifying the Industrial Property Convention of 1883 (adopted by this country as a party to the convention), which provides that a patent cannot be forfeited on account of failure to utilise it for three years after the deposit of the application, and only then when the patentee cannot show reasonable cause for his inaction. Under the Act of 1902, a patent may be revoked if the reasonable wants of the public cannot be satisfied by a grant of licenses, and the reasonable wants of the public are not met if the refusal of the patentee to work or grant licenses prejudices any existing industry or the establishment of a new one. Two applications under the Act of 1902 have already been referred to the Privy Council, but have not yet been decided, and the Government will not be prepared to propose further legislation until the provisions of the Act of 1902 have been proved to be ineffective. The Associated Chambers addressed a similar communication to the Premier, who replied: "The Government would not be prepared to propose a further amendment of the patent laws, relating to compulsory licenses until the provisions of the section of the new Act have been found by experience to be ineffective. At present Mr. Balfour has no evidence before him which leads him to believe that this will be the case." It will be of interest to observe the spirit in which the Privy Council treats the pending applications for revocation.

**The Motorcar Act.**—At the Automobile Club last week Mr. A. Moresby White read a paper on "The First Year's Working of the Motorcar Act," in which he complained that magistrates extended the application of the statute beyond the point contemplated by the Legislature. Another grievance of the motorist was that the Bench were prone to convict simply because the defendant's license had been once endorsed. Earl Russell, who presided, declared that the time was rapidly approaching when motorists should formulate the amendments which they wished to have introduced into the Act. The measure was not so bad as they had feared. It was true that in the first 20 miles of a drive they would probably commit about 10 serious offences, but in practice they were only convicted once in 100 times. The real difficulty was the objection in the minds of the public to speed as such. His lordship humorously referred to the "wilful credulity" of magistrates who believed any evidence against motorists, regarding them as persons of criminal instincts, though it was consoling to see that even bishops shared such treatment. Mr. Staplee Firth, who has appeared for the defence in numerous prosecutions for excessive speed, characterised the Act as the worst piece of legislation on the statute book. One police-sergeant always referred in court to "the vehicular traffic, the pedestrians, and the little children" who "might" have been present, and it was very effective in securing convictions, until at length the motorist's advocate began to prompt him when he came to this stage of each case, and would say, "What about the little children?" Even the Bench saw the point, and the sergeant dropped that part of his evidence. Mr. Firth made the important announcements that Mr. Horace Avory, K.C., had given his opinion that motorists could not be convicted of obstructing the police if they warned other automobilists of traps, and that it had been discovered that the 10-mile limit in the Royal parks, under which numbers of motorists had been convicted, without the slightest suggestion of danger to the public, was entirely illegal, as it had not been submitted for the sanction of Parliament.

**Tramways and Light Railways Association.**—A party of this institution assembled at the Oxford-circus Station of the Central London Railway on Monday for the purpose of inspecting the company's works. The company included Messrs. A. L. C. Fell (London County Council), J. W. Courtenay, C. H. Gadsby, P. Gadsby, W. H. Sayers, S. Sharp, and Ernest Benedict (secretary of the association). Mr. G. C. Cuningham, the general manager, and Mr. E. P. Grove, engineer, met the party at Oxford-circus, and accompanied them to Shepherd's Bush, where the visitors were shown over the splendid power station. As this is so well known, a brief description will suffice. The generating engines in the main house are six horizontal, cross-compound, condensing machines, made by Allis, of Milwaukee, U.S.A., running at 96 revolutions per minute. The electric generator is fixed directly on the flywheel shaft. Each is of 750 kw. capacity, or about 1,000 h.p. Not more than four engines are required at the time of greatest load, so that there is always an ample reserve of power. The boiler-house contains 16 Babcock and Wilcox water-tube boilers and four Lancashire boilers. Klein cooling towers are used to cool the condensing water, and the water supply is obtained from an artesian well on the premises. The amount of current amounts to about 50,000 units per diem. The grand total for the six months ended June 30 last was 8,981,878 units. The coal used is almost entirely smokeless Welsh washed peas. Current is generated at 5,000 volts alternating, which is converted into 550 volts direct at transformer stations at Notting Hill Gate, Marble Arch, Bond-street, and Post Office. Besides the power production directly from the generating station storage batteries are maintained to supply power for emergency lighting. These batteries are installed at Queen's-road, Bond-street, and Post Office Stations, and in the event of power going off from the main supply the current from these battery stations is immediately switched on, so as to keep up the lighting throughout the system. Car-sheds for the storage and overhaul of all trains are situated at the Shepherd's Bush Station, in addition to repair shops for the rolling-stock. It should be mentioned that the party also visited the Bond-street sub-station.

**Electrical Operation of Textile Factories.**—Before the Manchester Section of the Institution on Tuesday a paper on this subject was read by Mr. H. W. Wilson. After describing the advantages of electrical driving for large textile factories, the author dealt with the question of power costs. He found that in a modern spinning-mill of good size it may generally be taken that the generation costs by steam per indicated horse-power hour averages about $\frac{1}{12}$d., or about £1 per indicated horse-power year. Allowing for repairs, interest, and depreciation (interest and depreciation being taken at about 10 per cent.), the total cost per indicated horse-power year comes out at something of the order of £2. 5s. to £2. 10s. In the case of a weaving-shed, which is normally a smaller undertaking with less engine power, causing the proportion of standing charges per indicated horse-power to come out higher, the cost may be taken as between £2. 10s. and £3. 5s. per indicated horse-power year. The author considers these figures remarkably good, and in point of economy alone difficult to improve upon. In a cotton mill the working load factor is generally something considerably below the maximum, owing to a percentage of the machinery for sundry reasons standing idle at a given time; but some curves taken by the British Thomson-Houston Company show an average load factor of about 90 per cent. In this case, the mill being electrically driven, the transmission losses were small, but it has to be remembered that the greater the steady transmission losses the higher the apparent working

Digitized by Google

load factor. The author calculates that a well-arranged electrical generating plant for a mill of fair size should be able to produce energy, after allowing 5 per cent. interest and 10 per cent. depreciation in the capital cost of the plant, at about 0·3d. to 0·35d. per unit. The centralisation of power was incidentally touched upon in the paper, and the author intimated that in a district like Bolton or Oldham and the surrounding townships, he thought it would be possible for a very large generating station to supply energy at a cheaper rate than mills could provide power themselves. As the mills are only running during the daytime, the resultant load factor would not by itself be very high, but if, by the offer of special terms, other manufacturers could be induced to take power when the mills were stopped, such a station should be able to produce power at extremely low rates.

**Telegraph Employes.**—The Postmaster-General, in company with the Chancellor of the Exchequer, the Financial Secretary of the Treasury, and other high officials, last week received a deputation representing telegraph servants and others. The object of the deputation was to urge the adoption of the recommendations submitted by the Bradford Committee, which comprised several measures for improving the conditions of service. The delegate of the Postal and Telegraph Clerks' Association stated that the employés had heard with dismay that the Postmaster-General was not prepared to accept these recommendations in their entirety, as the concessions named by the committee would largely allay the discontent. Lord Stanley stated, in reply, that the report of the committee had received careful consideration, not only by himself, but by the Government, since the last session of Parliament. He must, however, disclaim any suggestion that the deliberations of the committee were to be regarded in the light of an arbitration, as Mr. Chamberlain had simply appointed a committee "who will consent to examine the scale of wages now paid, and who will report for my advice and information as to whether they consider the wages adequate or not." One member of the deputation had stated that the Post Office made a profit of four or five million pounds because the employés did not receive adequate remuneration, and the same representative intimated that the whole, or, at any rate, the greater part, of this sum ought to go in improved remuneration. Few people will be surprised that Lord Stanley characterised this suggestion as "very alarming in the present state of our finances, or at any time." Although the Government were unable to accept the Bradford Committee's proceedings as an arbitration, his lordship stated that they had been largely guided by the valuable evidence contained in the report when formulating improved conditions of service. The new conditions have yet to receive the approval of Parliament, and Lord Stanley will introduce the subject in connection with the Estimates. A general outline, however, was given to the deputation concerning the reforms which the Government has in view. An "additional increase of pay at the age of 25" will be given to telegraphists, this being prompted by considerations of matrimony. The request by some employés that their wages should be paid weekly instead of monthly will be acceded to. For women telegraphists there will be a higher minimum rate of pay in London and the largest provincial towns, while in the smaller offices there will be a higher maximum. The whole question of the learners is under consideration. These concessions seem pretty substantial, but one of the delegates frankly stated that they were far from satisfactory to the deputation. Presumably a *plébiscite* of the employés will be taken, and in one or two cases has already been taken, dissatisfaction being expressed with the Postmaster-General's reply.

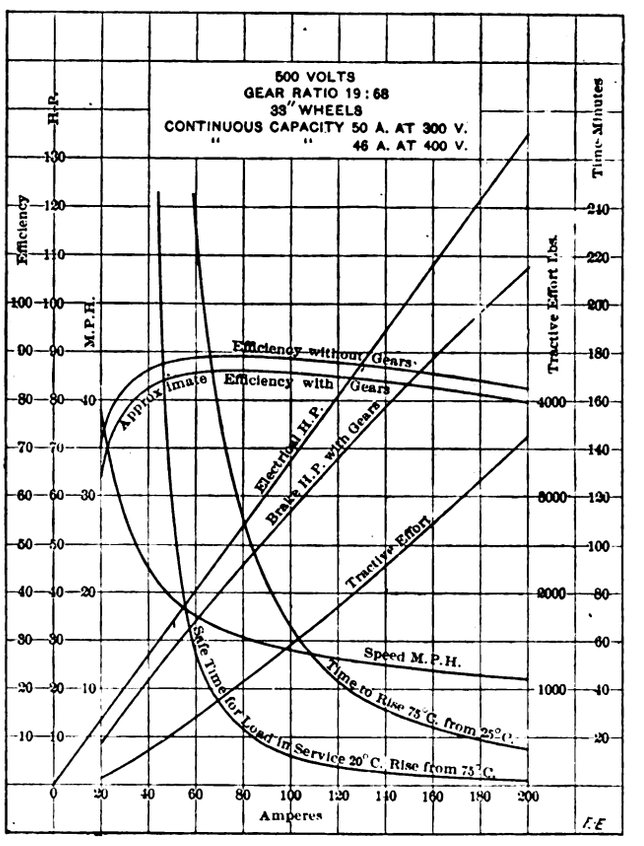
**The "Times" and Wireless Telegraphy.**—There was a large attendance at the Society of Arts on Wednesday evening, when, under the presidency of Sir William Preece, a paper was read by Captain Lionel James detailing his experiences in the Far East on behalf of the *Times* and wireless telegraphy. Captain James prefaced his remarks by the statement that he "knew nothing at all about wireless telegraphy." The paper, in fact, did not purport to deal with the scientific aspect of the subject, but comprised a history of the enterprise. As such it was highly interesting, though most of our readers are doubtless already acquainted with this, a long descriptive letter sent from the seat of war by Captain James having been reproduced in these columns by the courtesy of the editor of the *Times*. It was five years ago that Captain James commenced to take an interest in the results which were being attained by wireless telegraphy, as it seemed certain to him that, sooner or later, "occasion would arrive when it would be practicable to apply to journalistic enterprise this marvellous adjunct to the world's system of communication." It was the success of the de Forest system in the field of American Press rivalry during the yacht races of 1903 that caused Captain James to favour that system. The paper contained some interesting particulars of the obstacles encountered by the operating party in erecting the masts, materials and labour being very difficult to obtain owing to the outbreak of war. Dr. de Forest had stipulated for a shore station with 180ft. exposure and 120ft. on the moving station, but the causes just mentioned prevented more than 165ft. and 115ft. respectively being available. The Japanese treated the party with courtesy, but the Russians promised them a short shrift Whilst regretting that their operations should have been vetoed at such an interesting juncture, Captain James recognised that the course was dictated by vital political considerations. For the rest, the paper contained an entertaining, not to say thrilling, account of several incidents in the compaign, and a number of lantern views added to the interest of the occasion. Sir William Preece, in complimenting the author upon his paper, remarked that less importance was now attached to the altitude of the antennæ, the electrical equipment being the primary factor. Captain James had really performed his work in the Far East too well. If he had done it indifferently it would not have caused such a sensation, and would have escaped prohibition. At the same time "wireless" must necessarily be the auxiliary to, and not a substitute for, the cable. In answer to Mr. Cuthbert Hall (Marconi Company), Major-General Stirling, and other gentlemen, Captain James stated that he had selected the de Forest system because it was, practically speaking, impervious to interruption by other operators, and enabled messages to be transmitted much more rapidly.

**Montreal.**—Amongst the features contained in the report of Mr. S. E. Fedden, manager of the Sheffield Corporation electric supply department, on his recent Transatlantic tour, is a review of the electric lighting system of Montreal, the largest city in Canada. The energy is supplied from three water-driven turbine power-houses—viz., the Chambly, the Lachine, and the Shawinigan stations—which are situated 5, 17, and 85 miles respectively from the city, and in consequence of the long distance over which the power has to be transmitted the voltages are raised to 5,000, 25,000, and 50,000. Two of the stations—the Chambly and Lachine—are owned and worked by the Montreal Light, Heat, and Power Company, which company has the entire control of the electricity supply in Montreal. The number of consumers connected to their mains is 10,600 for lighting, 880 for power, etc., or, say,

Digitized by Google

3·3 per cent. of the population, as against 0·8 per cent. in Sheffield, though such comparisons, of course, are very approximate. In addition a large supply of energy is taken for street-lighting purposes and tramways, some 85 million units being consumed per annum. The big motor load enables a very high load factor to be obtained, which averages 75 per cent. throughout the year. This is largely owing to the arrangement of charges, which are extremely low to very large customers, on condition that they take no current during the dark months between 4 and 7 p.m. This entails very simple changes in the working hours, quite possible to many trades, and, Mr. Fedden remarks, is worthy of more attention than it has yet received in this country as a means of reducing the overlapping of motor and lighting loads at the peak time, which does much to keep up the capital cost and price per unit. At the Chambly station, 17 miles distant, the plant capacity is 17,000 kw. Current is generated at 2,200 volts two-phase, and by the use of specially connected step-up transformers is converted to three-phase 25,000 volts for transmission by overhead wires to the various sub-stations in the city, and from there it is distributed to consumers' premises either two or three phase alternating or direct current and at varying voltages. The Lachine station, which is only five miles away from the city, has a total capacity of 6,000 kw. The current is dealt with in a similar manner as at the Chambly station, with the exception that as the distance for transmission is much less the pressure is only stepped up to 5,000 volts. The third station, which is situated 84 miles away, is owned by the Shawinigan Water and Power Company, who are under contract to deliver to the sub-stations of the Montreal Company a supply equal to 5,000 kw. To enable the owners of the power works to do this, special apparatus has had to be installed to bring the frequency into line with that used in Montreal. Three aluminium lines have been erected to transmit the current over this great distance at a pressure of 50,000 volts. In addition to the water-power plants the Montreal Company have several steam plants in the city which are kept in reserve in case of breakdown. These plants are capable of producing from 6,000 kw. to 7,000 kw. There are five sub-stations in Montreal, the three principal ones being tied together by means of a 2,200-volt tie line. At these three sub-stations the energy received from the generating station is transformed and converted to alternating current at 2,400 volts, 63 cycles, two or three phase. Besides the supply to Montreal the Shawinigan works deliver electrical energy to other towns and villages. A novel feature with regard to the heavy transformers which are in use is that they are placed on small trucks and wheeled to their position, thus obviating the necessity of a crane in the transformer-room, and leaving overhead clear for the carrying of the high-tension wires.

**New Tramway Motor.**—An account of the No. 93 Westinghouse tramway motor, which retains the successful features of the No. 56 type, but is designed to meet increasingly rigid traffic demands, appears in the *Street Railway Journal*. The motor has a continuous capacity of 50 amperes at 300 volts, or 46 amperes at 400 volts It will carry safely any loads within the range shown on the accompanying diagram, provided that the integrated heating effect does not exceed the heating effect caused by the continuous application of the above currents at the corresponding voltage. In a shop test at either of these loads the rise in temperature of the windings of the motor during an all-day run will not exceed 75deg. C., but it is calculated that in actual service the rise would not usually exceed 55deg., owing to the better ventilation. For short periods, such as the rush hours of service, the motor may be operated with loads in excess of its continuous capacity, and under these conditions a higher temperature will be reached, though still within safe limits. The poles have projecting tips which serve the double purpose of giving a proper distribution of magnetic field and retaining the field coils. The coils, which are formed of copper strap wound on the flat, are heavily taped, and repeatedly dipped and dried, and impregnated with special insulating compounds, rendering the entire coil moisture proof and practically indestructible. The armature core is made up of a soft-steel punchings, built up on a cast-iron spider. Air-ducts are provided between the punchings, which connect with ventilating spaces in the spider, this arrangement providing an excellent circulation of air. The commutator is of the straight-bar type, without neck. There are 135 bars of hard-drawn copper, specially insulated and built up and clamped on a cast-steel bushing. The commutator bushing is then forced on the



armature spider and securely keyed to it, preventing any vibration between the commutator and armature core. The brush-holders are of the sliding type, with shunts. Two cast-brass arms are fastened by insulated bolts to the upper frame. Each arm carries two spiral phosphor-bronze brush springs, each of which bears upon a brush. The two brushes are placed side by side in the slot, each extending half-way across the commutator. This arrangement reduces the inertia of each moving element, and allows it to follow the surface of the commutator very closely, avoiding any sparking due to "chattering." The armature may be swung down with the lower frame, or retained in the upper part, rendering the interior of the motor perfectly accessible. To give access to brushes and brush-holders there is a large opening in the upper casting over the commutator. This opening is closed by a dust-proof malleable iron lid, which may be removed when conditions permit, with better ventilation and consequent increase of capacity. The general performance of this motor, which has a nominal capacity of 50 h.p. at 500 volts for one hour, is illustrated by the accompanying diagram.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

SIMPLE OR SIMPLEX MULTIPLE-CIRCUIT WINDINGS.

**The Simple Gramme Ring.**

Without doubt one of the most beautifully simple inventions in connection with modern electro-mechanics was the idea of the ring winding, which is named after the great French pioneer: it forms a natural starting point for the discussion of other varieties of armature winding; and, therefore, we will first consider its action in some detail. Fig. 1 shows a diagram of such a winding as applied to a four-pole machine.

It consists of a series of spirals of wire, such as A, B, wound about an annular core, the last turn of the last spiral being connected to the first in regular order, so that the whole winding forms an endless helix. It is connected regularly to a series of commutator segments as shown in the figure, and because it is an endless helix it is called a "closed-circuit" winding, though this term

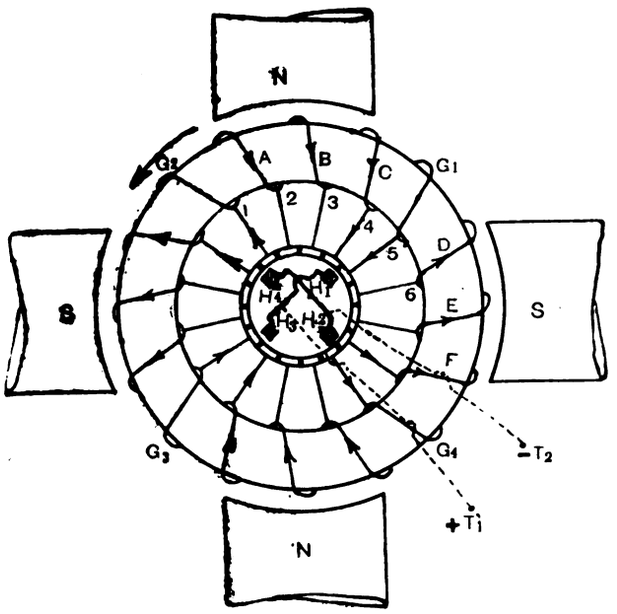

FIG. 1.

has no relation whatever with the external circuit connected to the brushes.

**Re-entrancy.**

Now all the windings which we are going to examine are similar in this respect, that they are endless, or (as it is sometimes expressed) they close upon themselves.

A winding which closes upon itself is called a re-entrant winding. I come, therefore, to the first definition:

*An armature winding is said to be re-entrant when it closes upon itself; or when, irrespective of core or commutator, it forms an endless band.*

This definition, simple though it is, is a sufficient interpretation of the word re-entrant. It evidently implies, in the case of a single winding, that if the core upon which such winding is placed and the commutator to which it is connected could both be dissolved out of, or removed from, the winding without otherwise disturbing it, and if the winding were then pulled, it would be found to consist of a single so-called endless band. Similarly, if a winding were "doubly re-entrant," and the same process were carried out with it, we should expect two separate and independent endless wire bands to be the result. On this we base the notation; which is used throughout in this work and in Parshall and Hobart, but which does not always agree with that found in other works. A singly re-entrant winding is denoted by a single band or circle, and a doubly re-entrant winding will therefore be denoted by two bands or circles. This system will be explained more fully presently, as well as *multiple re-entrancy*.

Since the windings which we shall discuss here are all *regular* windings—*i.e.*, consist of a number of conductors and connections quite regularly spaced around the armature—it follows that the closing of the winding upon itself must be such that it comes about *naturally*, not by some special connection inserted. There are cases where such special connections have been used, and with success, but they are to be avoided whenever possible as tending to destroy the symmetry, and so to set up the circulation of "parasitic"* currents in the windings themselves.

**Position of Collecting Points or Brushes.**

In the example which we are considering (Fig. 1)

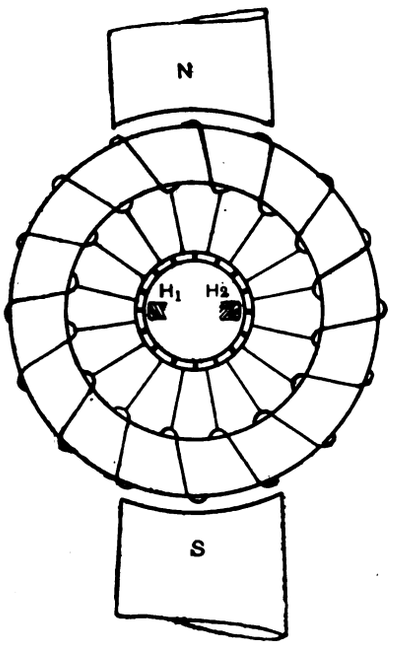

FIG. 2.

the winding passes sixteen times about its core before finally returning to the starting point. Calling such a section of the winding as that lying between A and B one spiral, we may say that there are sixteen spirals on the armature, and since there are four poles, we have four spirals per pole. Now let the direction of rotation of the armature and the polarity be as shown in the diagram. Then the induced electromotive forces are as shown by the small arrows where marked on the spirals, as at E, F, etc. In consequence at points $G_1$, $G_2$, etc., we have opposing and equal electromotive forces which are such that, if we arrange connections at these points, $G_1$ and $G_3$ will be positive with respect to $G_2$ and $G_4$. At points equally spaced around the winding then, such as 1, 2, 3, 4, etc., let connections be made to commutator sections as shown in the diagram; then, from what has already been stated, brushes must be placed at the four points $H_1$, $H_2$, $H_3$, $H_4$. $H_1$ and $H_3$ are positive brushes, $H_2$ and $H_4$ are negative brushes. We note that in passing certain points each spiral has the direction of its electromotive force reversed—that is, at each of these points two

* By "parasitic" current we mean a current not essential to the proper function of the machine: such currents usually flow round and round the windings themselves without passing through the external circuit, thereby causing a loss of energy and performing no useful work.

Digitized by Google

series of opposing electromotive forces meet. And these are the positions for the brushes, as is clearly shown in the diagram above.

**Number of Circuits in the Armature.**

If brushes $H_1$ and $H_2$ were joined we should have a circuit ($H_1$, D, E, F, $H_2$) in which the electromotive force acting would be as shown by the arrows, this electromotive force being that due to the action of the three spirals D, E, F. Exactly the same reasoning applies to a consideration of any other adjacent pair of brushes, such as $H_2$ $H_3$ or $H_3$ $H_4$: hence in a section of the winding lying between adjacent brushes there is a definite electromotive force, and from the consideration of the direction of the electromotive forces thus spaced round the armature, it follows that alternate brushes may be connected together and gathered into one group, which in turn is connected to a positive terminal, the intermediate ones being similarly joined to a negative terminal as shown. In this way the winding with respect to these two terminals, $T_1$ and $T_2$, becomes a system of four circuits connected in parallel. This is not so readily seen from Fig. 1 as it is from

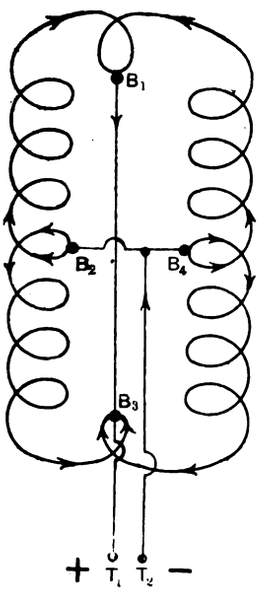

Fig. 3.

Fig. 3, where the armature winding is represented by the spirals and the brushes by the connections at $B_1$, $B_2$, $B_3$, $B_4$, $T_1$ and $T_2$ being again the terminals. By careful comparison Figs. 1 and 3 are seen to be similar, and Fig. 3 is exactly the same in effect as Fig. 4, which is clearly four parallel circuits of four spirals each. In practice, however, with a commutator, one spiral in each circuit is constantly short-circuited. Hence in Fig. 1 we only see three active spirals between any pair of brushes.

Another way of expressing this division of the armature into circuits is by saying that, since the armature in Fig. 1 revolves while the brushes remain stationary, there always exists an average of about four coils between adjacent brushes. If $T_1$ and $T_2$ are connected by some resistance, the electromotive forces in the armature will tend to set up a current: this current flowing, in the case of $H_1$, part from B towards $H_1$, and part from D towards $H_1$, so that each positive brush has two paths connected to it. Similarly with each negative brush; and there are two positive brushes and two negative brushes connected in parallel: therefore with respect to the external circuit connected to $T_1$ and $T_2$ there are four paths *through the armature* in parallel. Stress must be laid upon the above effect of having a plain Gramme ring placed in a four-pole field with four brushes, and it must be clearly understood from the very beginning that *no system of connection between brush and brush alone can result in placing two or more sections of the armature winding under different poles in series with one another with respect to the external circuit;* and, therefore, if it were possible to add to any existing bipolar ring dynamo another pair of poles with the same number of lines per pole and two extra brushes, by no possibility would the electromotive force of the machine be increased: only the current which might be safely taken from it would be doubled by reason of the fact that two extra parallel circuits had been added to the armature.

**Importance of Electrical Balance.**

From Fig. 1 we can also see that the omission of one or more brushes always renders the armature either out of electrical balance or partly useless. Moreover, if the brushes be not placed symmetrically about the commutator, a lack of balance follows. Thus, if we imagine $H_1$ moved sufficiently far toward D, we shall presently have the electromotive forces at C and D

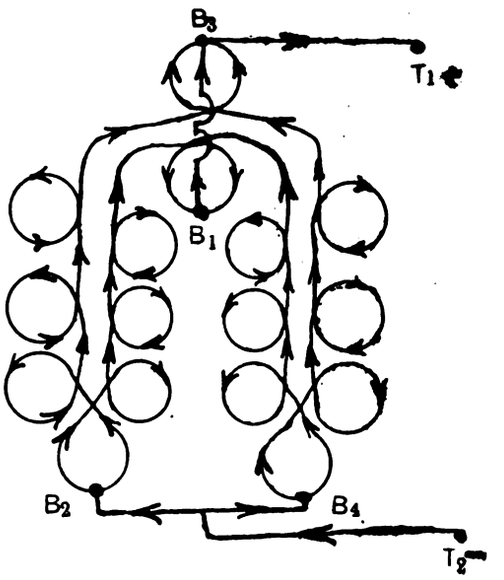

Fig. 4.

neutralising one another, the current from $H_1$ reduced, the spiral D carrying current in the wrong direction, resulting almost certainly in asymmetrically distributed armature reaction and parasitic currents flowing round and round the armature winding. Similar effects must ensue if the armature is eccentric to the field, so that in these armatures, central position in the bore and regular connections to the commutator with carefully adjusted brushes are of the greatest importance.

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

(*Continued from page 51.*)

**Messrs Siemens Bros. and Co. make a rather interesting oil switch, illustrated in Fig. 11. This depicts a two-way type, but the configuration of the oil-bath for the single way can be seen by the dotted lines. The bridging piece in this case is a single swing lever depending from the oil-tank cover, and engaging with a fixed contact hanging down from a similar position. The terminal of the swing link is fixed into an insulator, and fitted with a rubbing contact clip which engages with a sector forming the half of the**

Digitized by Google

clip casting of the swing link. A spindle passes through the box carrying the switch pieces for the three phases on an insulating sleeve, and a handle is fitted at the outside for direct operation, or a lever and links for distance control. A spring lever with a roller fitted ensures the switch remaining in either the on or off positions. An automatic release is provided if required.

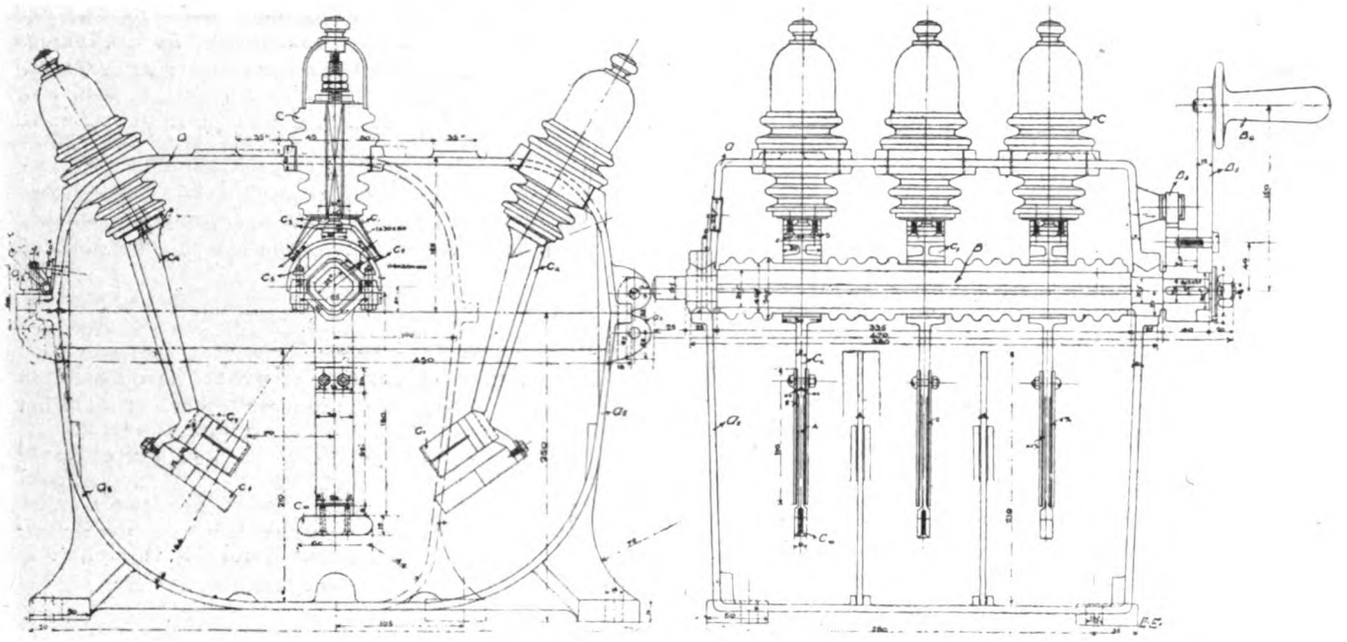

FIG. 11.—Box Oil Switch (Siemens Bros.).

Messrs. Cowan and Andrews, who have done so much for reverse-current devices for alternating and direct current circuits in this country, contend that electrical and pneumatic control introduces a risk of failure to be avoided if possible. They accordingly advocate direct mechanical control, and where this is not possible, electrical control at low voltage. Fig. 12 illustrates their lay-out for a high-tension switchgear, and from this it will be noticed that the operating panels are fixed upon a gallery and the high-potential fittings installed below, each section being enclosed by 4½in. brick walls, with substantial iron doors affording access to each cell. It is not essential that these fittings be placed below the operating board, as they can be arranged at the back, some distance from the board. Wherever the high-tension portion may be placed, however, the same principle of isolation is adhered to by placing a brick wall between the dangerous parts of the gear and the operator. In the figure the iron door is shown removed from the first cell, and the high-tension switch withdrawn for inspection.

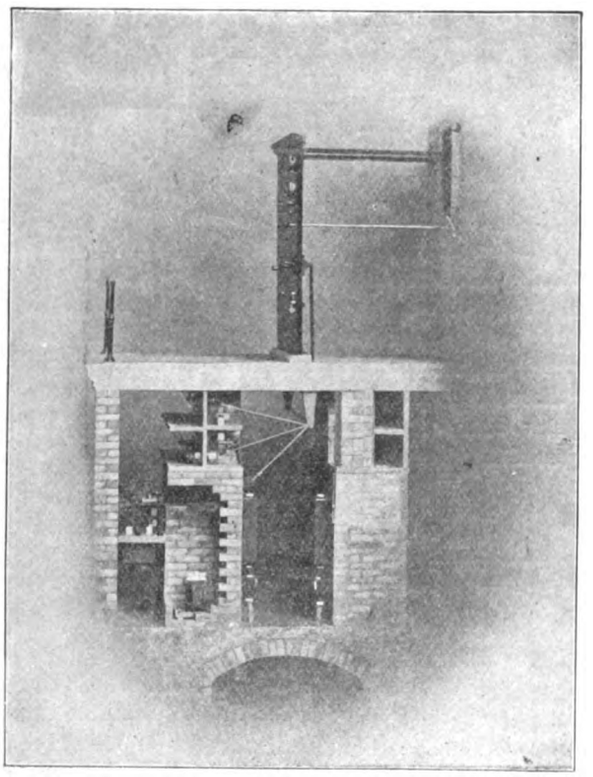

FIG. 12.—Distance Control Lever-Operated Gear (Cowan-Andrews).

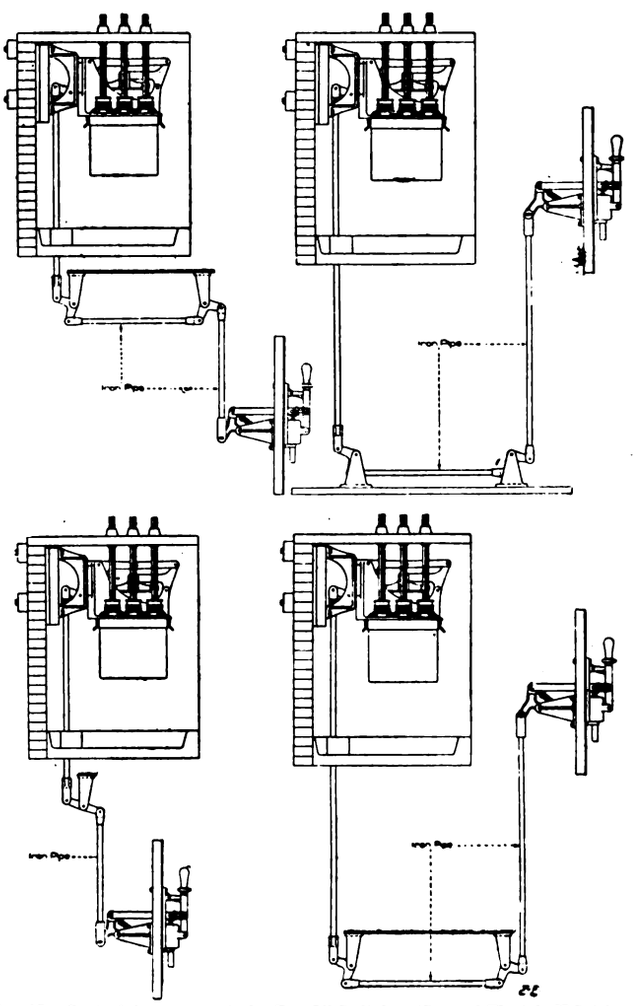

FIG. 13.—Control Arrangements for Box Oil Switches (General Electric N.S.A.)

Traversing rods are temporarily fitted for withdrawing the switch, but when in position the switch cannot be removed. On generator panels the synchronising transformer is placed immediately below the switch in the brick cell, and a ledge at the front side prevents the oil from spreading should it

Digitized by Google

boil over for any reason. The bottom of the cell is filled with sand to absorb any escaping oil. The oil switches are operated by bell cranks and levers passing through the back wall of the cells, thence through the gallery floor to the back of the operating board. There are no fuses either on generators or feeders, the former being fitted with Andrews's reverse-current release and the latter with a maximum-current device. The reverse-current release may be described somewhat in detail as it operates on an entirely novel principle. The main current so deflects the magnetic induction in a small transformer, that if a normal current be flowing, a secondary coil on the same transformer is excited which in turn excites a coil tending to hold the circuit-breaker catch "closed." A reversal of the main current excites another coil which tends to release the catch, and in this way a positive pull, definite and strong, is obtained. By this device relay circuits, wiring, and small batteries are dispensed with. By putting red and green lamps into the circuits of the respective coils, the condition of the switching device is readily indicated beyond all chance of error on the part of the switchman. The relative brilliance of the lamps also serves to denote approximately the load on the particular unit. Referring again to Fig. 12, it will be noticed that there are two rows of cells placed back to back, a passage being left in which mechanical gearing can be inspected. The automatic release gear and current transformers, enclosed in iron cases, are fixed in this passage, while the cables are brought up into it from a ment being suitable for either generator or feeder circuits. The control board is mounted separately on a gallery, and directly behind the board is a wall completely dividing the operating gear from the high-pressure portions. In case of fire this wall isolates the operator and the control board, and it may be the engine-room wall or a division built up in the switch-house. The control board is merely a number of marble or slate slabs in an iron framing staged out from the wall, and accommodating on its back the exciter bars and field-breaking resistance. The field rheostat is mounted on the back of the dividing wall and geared through chains and spindle to the regulating handwheel. The only physical connections between the high-tension gear and the control board are the low-tension instrument and relay leads and the rod for operating the high-tension switch.

The high-tension gear comprises a wall with two working faces. On that facing the control board, starting from the bottom, are mounted the cable-dividing box, the instrument and relay transformers, and the oil switch. The latter is at the top, and divided from the transformers by a heavy stone slab, with insulated bushes for the connections. A heavy guard plate is fixed some distance above the oil switch, and the connections therefrom pass to an insulated connection fixed in and through the wall. From a corresponding position on the opposite face the connections descend to a section switch and thence to the 'bus bars. Where leads of opposite phase pass through the 'bus-bar

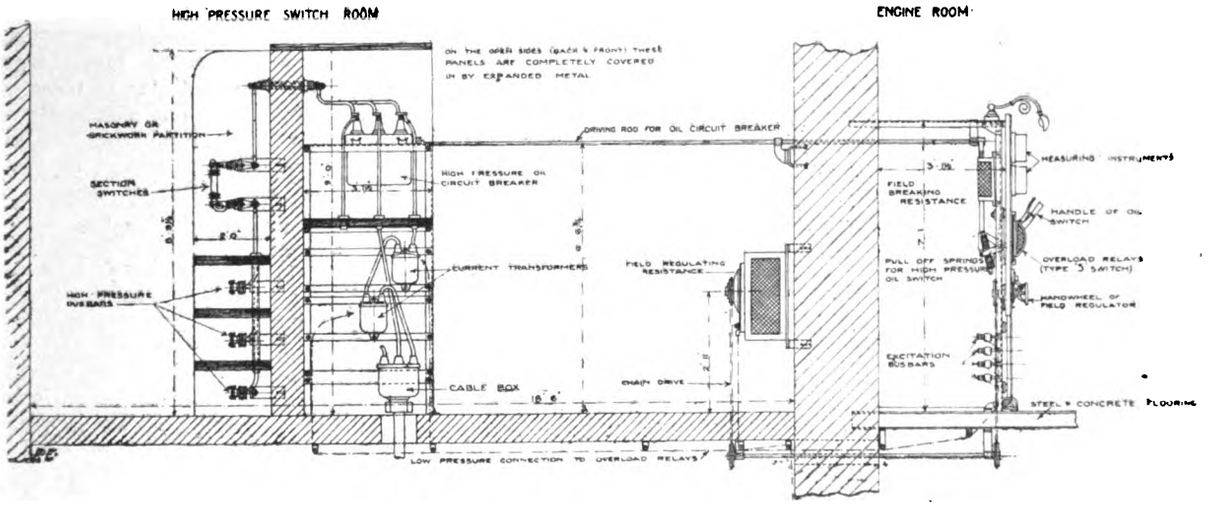

FIG. 14.—Lay-out for Box Oil Switches (Witting-Eborall).

conduit under the floor. Each conductor is passed through its own current transformer, and thence to its particular switch in its own individual cell. In the opposite passage to be seen on the left the 'bus bars are carried longitudinally in stone cells immediately above the oil-switch cells. They can be readily inspected from this passage, and section switches are fixed where required in the lengths of bar. These switches are placed each in a separate cell accessible from the same passage, and are worked mechanically from the main operating panels. The isolating of these switches precludes all possibility of any arc, started at switch opened in error, spreading to the 'bus bars. Rheostats and low-tension exciter gear are placed behind the operating panels, alternately upwards and downwards, to economise space. In designing this gear the makers have had in mind the destructive effect of breakdowns, and endeavoured to confine this to its source without fear of spreading to other apparatus.

### LAY-OUTS FOR MECHANICAL CONTROL.

In Fig. 13, methods of operating the oil-box switches previously mentioned are clearly shown, and each emphasises the flexibility of the system. In no case is the operating handle placed *above* the switch, though the reverse is done for obvious reasons. The switch can, of course, be placed below the operating board in a cellar or basement, but such a proceeding is not to be recommended.

A typical lay-out for the switches shown in Figs. 8 and 9 (Witting-Eborall) is depicted in Fig. 14, the arrange- chambers, they are enclosed in insulating tubes. Feeder connections from the same bars are brought back through the wall to a switch and cable box on the opposite side and in line with the generator switches. A lay-out similar to the foregoing is equal to a normal capacity of 2,500 kw. per panel.

*(To be continued.)*

## TRAMWAY OVERHEAD EQUIPMENT MATERIALS.*

BY H. M. SAYERS, M.I.M.E, MEMBER.

This audience is well aware of the general purposes to be fulfilled by a satisfactory overhead equipment, but to make an orderly study it is necessary to commence by a brief analysis of the mechanical and electrical conditions which must be satisfied in order that the structure may serve its purpose with the maximum economy and efficiency. The necessity of studying appearance should not be a serious addition to the primary engineering necessities, for the appropriate use of materials and obvious adaptations of means to ends satisfies the æsthetic as well as the practical sense, and where incongruity with architectural and natural beauties is the danger, unobtrusiveness will probably give better results than any elaborate attempts at ornament.

The first mechanical condition to be satisfied is evidently that of safe and stable support. The trolley wire has to resist, in addition to the stresses on a suspended wire, the

* Paper read before the Tramways and Light Railways Association.

Digitized by Google

repeated upward thrust of the trolley pole and the friction of the trolley wheel. The attachments are exposed to reversed stresses of the nature of blows in both vertical and horizontal directions, and the wires being necessarily carried at a distance of several feet from the poles, any unbalanced longitudinal stress produces considerable couples upon the supporting structure. The second mechanical condition is that imposed by the function of the trolley wire as a suspended guide or rail for the trolley wheel to run on. This condition resolves itself into a necessity to follow the general lines of the rail track in plan—with some maximum permissible lateral deviation, and some maximum permissible change of horizontal direction at points of support. The permissible limits in both directions depend upon factors outside the overhead structure, some of them being the type of trolley boom and wheel, the size and speed of the cars, the radii of the curves, and the lay-out of junctions or other special work The effects of wind and snow are of relatively small importance as regards trolley wires, but must be given full weight in the erection of guard wires. The electrical conditions to be met affect the mechanical structure in so far as they prescribe the size and weight of the trolley wire, the necessity for efficient insulation being constant.

Time will not permit of more than quite general references to questions of design and erection of the line, excepting as they may affect the choice of materials and design of parts. I therefore take the different items of material in an order which is intended to be logical and consequent. The trolley wire comes first, its support and proper position being the principal object of the whole work. The stresses on all the supporting structure are evidently functions of the size and weight of the wire used, and to keep down the size, weight, number, and expense of supports the wire should be chosen as small as will serve the designed purpose. It is easy to show that there is no electrical necessity for using any wire larger than No. 0 S.W.G. (·324in. diameter), where the trolley wire is fed as usual from underground feeders at half-mile intervals, unless the traffic is extremely heavy. But on suburban or inter-urban lines carrying an infrequent service it may be necessary to avoid the expense of underground feeders, and to employ heavier trolley wires, or, preferably, overhead feeders. Heavy traffic, especially over curves of short radius, may also afford a reason for the use of larger wire in order to increase the life, and remove the risk of breakage on account of heavy mechanical wear. The most economical size of trolley wire to employ in any particular case is thus mainly a question of its life as a mechanical wearing part, the cost of renewal and the loss by scrapping having to be put against the capital expenditure. But it must not be forgotten that a heavier wire involves heavier poles and other supports, the cost of which must be properly brought into the account. The conditions are too complex, and at present too little determined by experience, to admit of the formulation of any general rule, but it is probable that where the conditions are very severe it is better to employ one of the harder bronze alloys than a copper wire of larger size. One reason for this is that the wearing qualities of hard-drawn copper wire are not directly proportional to its weight, the hardness diminishing from circumference to centre. This is well shown by the fact that the Post Office specification for such sizes as Nos. 12 and 14 calls for a breaking strain of 28 tons per square inch, whilst the usual trolley wire specification is equal to 22 tons, over 20 per cent. less. The effective thickness of the hard skin varies with the details of the manufacturing process, and very little seems to be known about the subject by users; but, from the behaviour of trolley wire under long wear, it seems probable that the hardness diminishes gradually, and, up to such sizes as No. 0, a considerable thickness is appreciably hardened. It is also possible that the rolling of the trolley wheel has a further hardening effect, but where the wheel rubs or grinds, hard abrasion removes the hard exterior, and the softer metal inside is soon reached. On these facts it is clear that a material that is hard right through should be preferred. Very little experience with these bronze wires has been made public, and as some are brittle and some pit badly under arcing, they should not be extensively adopted without trial. They are all of higher electrical resistance than copper, and therefore require feeding at shorter intervals if the traffic is heavy. The mechanical and electrical qualities required in trolley wire are well known, easily verified by test, and readily complied with by a considerable number of makers. Very high tensile strength should be regarded with suspicion as probably indicative of brittleness, and bending and falling weight tests should be made in such cases.

The next point in order after the size of the wire is its position in relation to the track; the choice lies between side and central wires. There is sometimes a conflict here between the claims of good working and the supposed interests of appearance, but the prejudice against span wire construction is happily dying out, and it is unnecessary to enter into any elaborate argument before this audience to show why and how the centre wire gives the best working. Assuming that centre wiring is adopted, the approximate position of the wire is given at once by the centre lines of the tracks, as shown on the permanent-way plans, or as actualy laid. There are sometimes material differences between track plans and execution, and it is often wasted labour to plan out overhead work in full detail from construction plans. It is far better to let the permanent-way construction get a good long start of the overhead; then pole positions can be laid out from the actual track centres, and the overhead work can be carried through continuously, and with the certainty of correct position. As overhead work does not take more than a fifth of the time required for track construction, there need be no difficulty in arranging for practically simultaneous completion of the two. Although exact positions cannot be taken from permanent-way plans, the number and size of poles and the general arrangements can be got out sufficiently well to order all necessary materials in good time. The maximum distance apart of supports is settled by the Board of Trade regulations at 40 yards; on straight lengths there is no reason for diminishing this, and it *is*, therefore, taken as the standard. But at curves, junctions, and termini the positions of poles have to be carefully considered, and so arranged as to take the longitudinal pulls of the straight lengths or tangents as directly as possible, to hold the trolley wire closely and firmly to the required curves, and to hold "special work" to its correct place. There is often but a limited choice for pole positions, especially at junctions where streets cross, and in all such cases an accurate large scale survey should be made, the trolley wire and special work laid down on it, and the best arrangement of span and pull-off wires that will suit the possible pole positions worked out The labour of drawing several alternatives will be well repaid by the workmanlike and satisfying appearance of the completed work, and by the absence of working troubles.

One essential point at these places is to anchor the straight lengths as directly as possible to a heavy pole. If such a pole can be placed at the intersection of the tangents it can take both anchor wires. The ends of the curves should also be anchored in the usual way. This anchoring is very important, because it makes the straight lengths and the curve work mutually independent, the span wires are not distressfully pulled out of line, and the pull-off wires intended to shape the curve have not to take indefinite components of the pull of the straight lengths. Most important of all, if any accident happens to the overhead work on either the curve or one of the straight lengths, its effects will be stopped by the anchoring. Anchoring is also necessary at section insulators, and it is advisable to anchor every quarter of a mile, even on a perfectly straight line, in order to localise the effect of a trolley wire breaking. Termini, curves, and junctions are the keystones of the whole structure, and when the pole positions at these places have been worked out, the tangents between have only to be divided up into equal lengths of as near 40 yards as circumstances permit, but never exceeding that distance. Side poles with brackets can rarely be used to carry wires central to the track, as the bracket arms would be unduly long; the choice lies between span wires and central poles. Where there is room central poles have certain advantages, especially that of neat or even

Digitized by Google

ornamental appearance, and their cost is somewhat less than that of span-wire construction. But as the clear way between the tracks has to be from 2ft. to 2ft. 6in. wider to give the regulation clearance between cars and standards, the total cost to the tramway undertaking is rather increased than diminished. They also have to be lighted sometimes at the tramway expense. To other traffic in a busy thoroughfare central poles are a nuisance and a danger, but where streets of magnificent width relatively to the traffic on them exist, the disadvantages may be inappreciable. On even slight curves centre poles are insufficient, as there is no means of "pulling-off" the outside wire, and if side poles are added for that purpose, they look very odd.

Feeding points have also to be reckoned with in laying out pole positions. The best way of cutting up the work into half-mile sections will depend upon many local conditions, but one constant consideration is to arrange that a fault on any section shall have a minimum effect upon the whole service, and, consequently, sections frequently terminate at junctions. Section insulators should be kept out of the junction special work, and, where this is complex or important, it is best to insulate it on all sides and feed it separately. Section insulators should not be put on curves, or on steep gradients. If the central wire has been decided upon, span-wire construction will be the prevailing type, excepting where central poles may be possible and preferred. It is just possible in some cases to carry a central wire from a side pole and bracket-arm. In the case of a double line these will be required on each side of the street, and it is hard to see what is gained in appearance by the substitution of two sets of bracket arms for one set of span wires. The bracket arms are much more conspicuous and the construction more expensive. Span-wire poles will be set out in pairs opposite each other on straight work, but on curves more and stronger poles are needed on the outside or convex side of the road than on the concave side, the pull of the trolley wire being centripetal. Bracket-arm poles should always be on the outside or convex side of the road.

Having arrived at the pole positions, the next point to determine is the strength of pole to be used in used in each. Generally speaking, three grades of strength will suffice. The Engineering Standards Committee has recently issued a standard specification for tubular tramway poles in which the three strengths are classed as light, medium, and heavy, and the strength defined by the loads needed to produce a temporary deflection of 6in. and a permanent set not exceeding ½in. under conditions fairly representing the working loads. The temporary deflection load may be regarded as the maximum safe working load, and the permanent set load as marking the commencement of danger by deformation. The loads are as follows :

| Class of pole. | Load for temporary deflection of 6in. | Load for permanent set not exceeding ½in. |
|---|---|---|
| Light | 750lb. | 1,000lb. |
| Medium | 1,250lb. | 1,750lb. |
| Heavy | 2,000lb. | 2,500lb. |

The light poles will naturally be chosen for straight line work, the medium serve for pull-offs on moderate curves and for feeder poles, and the heavy for anchor poles and for carrying heavy special or curve work which involves resistance to the direct longitudinal pull of trolley wires. Occasionally heavier poles than the standard "heavy" class may be needed, but these occasions are rare, and may often be avoided by dividing the load between two "heavy" poles. The choice as between sectional and taper poles is mainly one of taste and price. That the appearance of a pole of uniform taper is better than that of a pole built of three parallel sections is a general opinion. At present, for equivalent mechanical tests, taper poles to standard dimensions are dearer than sectional poles, and somewhat heavier. The absence of the swaged joints is put forward as a mechanical advantage, but it is very rarely found in practice that a sectional pole fails at the joints. If taper poles are used, it is desirable to have them solid rolled, as a lap weld the whole length of the pole may prove a line of weakness. Solid rolled tube is an improvement in sectional poles, but there is not a great risk of poor welds in these comparatively short lengths, and if the joints are set at 120deg. in plan, as they should be, the pole as a whole will show no line of weakness. Wooden poles have been very little used in this country, but are somewhat extensively employed in the United States and some Continental countries. They will rarely be tolerated in town work here. Wooden poles should be chosen to give the same temporary deflection as would be called for in steel poles. As this depends upon stiffness, it will generally be found that very thick timber is necessary, and the poles will have a stumpy and heavy appearance. The first cost will generally be lower than for steel poles, but the ultimate economy is somewhat doubtful, and should be considered with full knowledge of the special conditions, especially the probable life of the wooden pole in the local soil and climate. In any case the poles should be creosoted to the Post Office specification, and they should not be set in concrete. Lattice poles can be purchased and are sometimes used on the Continent. They are said to be cheaper than tubular poles of equal strength, but are very ugly, and it is probable that the painting necessary to preserve them from rapid corrosion in this climate will neutralise the initial saving.

The type, positions, and sizes of poles being settled, the intermediate supports between poles and wires claim attention. The choice lies between span wire and bracket arms, but it is frequently necessary to use both constructions in different parts of a tramway network. If the central wire has been chosen, span-wire work will generally predominate, but there are many exceptions, especially on systems which are mainly composed of single lines with turn-outs. Where bracket arms are employed it will be wise to use the short span-wire arrangement generally known as the "bowstring." The older construction, in which the hanger is clamped directly to the bracket arm, is probably obsolete. The rigidity of the attachment is a serious evil, imposing upon the hangers and the trolley boom a considerable blow, detrimental to every part, especially to the insulation of the hanger and clamp. It may further be said that it is not possible to provide a satisfactory permanent insulating sleeve for the clamp in this climate, all materials tried, so far, failing in a comparatively short time. The "bowstring" suspension is an improvement, but it is still far more rigid than the span wire, and, therefore, results in greater wear of wire and trolley wheels, and in deterioration of insulators, besides leading to de-wiring at speeds much lower than can be run with safety on span-wire work. This detrimental effect of rigid or semi-rigid attachments is sometimes overlooked, or the true cause is not recognised, although it is simple enough. The trolley wheel of a moving car presses the trolley wire upwards with a force which usually equals or exceeds half the weight of the span of wire. At the centre of a span it will therefore lift the wire considerably, possibly to the height of the points of support; from the centre onwards it is, however, depressed with increasing rapidity, as the stiffness of the wire comes into play, and will be below the level of the ear some distance before it arrives there. It, therefore, meets the rigid ear while rising rapidly, and delivers a blow the force of which is the product of the effective mass of the whole boom and head and the square of its upward velocity. At some speeds the rebound will take the wheel flanges clear of the ear and, if there is any side pressure, de-wiring results. The noise and the flash invariably seen on the passage of trolley wheels under bracket-supported hangers demonstrate the correctness of this explanation. After passing the ear the wheel at first descends, but soon commences to rise again up to about the middle of the next span. Its path is therefore a wavelike one with a high crest in the middle of each span and a small steep one at each ear. Besides the effect of the blow upon the ear, the insulating materials, and the trolley wheels and boom, the wire is worn by arcing and damaged by bending. It is, therefore, not extraordinary that failures of insulators and breakages of wire at ears are more common on bracket than on span-wire work. If bracket-arm construction is used, the bowstring should be made as long as practicable in order to get the maximum flexibility. The flexibility of a span-wire construction greatly reduces the blow upon the ears, as the span wire also rises to the trolley pressure, and the ear more readily

Digitized by Google

aligns itself with the wire, but, at high speeds, the effect is quite perceptible, and, for railway speeds, the longitudinal suspending wire carrying the trolley wire by hangers at short distances and so approximating to a system with a constant vertical rigidity from point to point is essential.

Span, bowstring, and pull-off wires are generally of galvanised steel, but in many towns this material has but a short life on account of atmospheric pollution, and in such cases phosphor or silicon bronze wire should be used. This applies equally to guard wires and their supports; whichever is used the metal parts of the suspension fittings should be of similar metal. There is no means of preventing galvanic corrosion where dissimilar metals are in contact, and such contact should be avoided. The use of iron insulated bolts screwed into brass ears is almost universal, and frequent trouble results at this point. Gunmetal bolts would be better, but there is some difficulty in getting them made. The size of span wire should not be less than $^{7}/_{14}$ S.W.G. There seems no reason for using larger wire, but such use is quite common even up to the monstrosity of $^{19}/_{13}$. This wire should have a breaking point equal to from 35 to 40 tons per square inch after stranding; the galvanising should be carefully examined and tested in the manner prescribed by the Post Office. Galvanising that is originally defective, or that cracks and peels off in erecting, is useless; the wire will rust through at the unprotected points in a brief period. To secure the wire at the poles, it should be laid around a horse-collar thimble of size proportioned to the size of strand, and properly bound with galvanised charcoal wire—not twisted up. Better than the thimble is a shackle or reel of porcelain with a central hole to take the strap bolt. Porcelain is a far better, more durable, and cheaper insulator than any of the compounds used in turnbuckles, globe strains, etc. There is no need to provide any tension adjustment at the ends of span wires—insulated turnbuckles, Brooklyn strains, etc., are quite unnecessary, and represent wasted money. With a dynamometer on the drawvice, or by the measurement of the sag from the ground, span wires can be put up with the greatest uniformity, and the certainty that the trolley wires will be carried at their correct level. This level can be checked, if desired, by loading the span wires at the correct points with weights represent the working load, but this only needs to be done once for each width of street.

Bracket arms are generally made of 2in. steel steam tube either screwed or expanded into a socket on the pole clamp. These arms are often much too long for safety. A 2in. tube 12ft. 6in. long, fixed as a cantilever, and loaded with the weight of a span of trolley wire and the suspension fittings, is very near its breaking point. Longer arms are therefore entirely dependent upon tie-rods. The longer the arm the less efficient the tie-rod, owing to the more acute angle between the two members. As generally made, tie-rods are pulled up by a nut, so that their effective strength is the resistance of the threads to shear. Bracket arms 18ft. and 20ft. in length are therefore extremely unsafe, having practically no margin of safety. It is better to use eye-ended tie-rods and dispense with nuts, and no real difficulty arises in erection if the clamps are fixed at measured distances, so that the brackets and tie-rods make the correct calculated angle; but if adjustment is necessary it is best provided by a long, solid, right-and-left-threaded sleeve fitting the two parts of the rod like a rigging screw. Struts are usually inapplicable, but if the scrollwork can be made to give some support, so much the better. Bracket-arm pole clamps should be of substantial length and a good fit on the pole by internal fitting rings at top and bottom. The bolts should fit through long bored sockets in the planes of the fitting rings, and be kept close in to the poles. The socket receiving the arm should be of ample length and well thickened out to the body of the clamp. In fact, in designing bracket arms and their fittings the stresses and strains should be calculated out as for a loaded cantilever, ignoring the tie-rod, but adding 50 per cent. to the dead weight to allow for the rolling load and its hammering effects. Then the tie-rod and its fastenings should be designed to carry the same load safely. Malleable cast iron is the best material for pole and bracket-arm clamps and bowstring brackets. These last are often too short to give proper clearance, and are spaced too close on the bracket to give the elasticity so desirable. They should be pinned or otherwise secured so that they will not slide along the arm. Porcelain shackles should be used as the secondary insulation of bowstrings.

On straight work the "straight line" hanger is the best insulated fitting, but on curves, and wherever there is a probability of lateral pressure on the wire, the pull-off pattern must be used. The caps of these should be provided with some form of locking device, and a soft-leather washer should be placed between the head of the insulated bolt and the cap. The insulating material on the bolts is far from perfect. The compounds are trade "secrets," but very slight investigation shows that shellac is the insulating and consolidating element in nearly all. Mica, asbestos, and other mineral substances add some toughness to the mass, but its mechanical qualities are generally poor. Whilst new the insulating qualities are very good, but in a short time the atmosphere deposits dirt on the exposed surface, and sooner or later in damp weather a trifling leakage of current chars the surface and breakdown speedily follows. This should not happen if the secondary insulation remains good, and if porcelain is used, such breakdowns are very rare, because a porcelain surface does not char with a small creeping leak, it dries up, and the leakage ceases. A somewhat tough vulcanite has been introduced. Vulcanite has had extensive trials in telegraph practice and obtained a bad reputation. Tramway conditions are less favourable to its permanence. This matter is a really serious one, and the insulated bolt is probably the most unsatisfactory item of the whole overhead equipment. The cure may be found in redesigning the arrangement in such a way as to remove the insulator itself from so trying a position, but there are obvious difficulties. The usual practice of keeping the two trolley wires for up and down directions separately insulated and separately fed is highly advantageous. But at junctions this becomes very difficult. Insulated crossings are a variety best avoided, and, as above stated, the best course is to feed junction work separately; the next best thing is to feed it through one wire only of one of the junctioning lines, and to insulate the junction from all the other wires. In bowstring suspensions care should be taken to provide ample clearance above the cap of the hanger. Sometimes only a small fraction of an inch is left between the cap and the bracket-arm tube, with the result that at every passage of a trolley wheel the hanger strikes the arm, damage soon resulting.

The soldered ear is the best form of attachment for the trolley wire. Many patterns of mechanical ear have been devised and tried, but it is hard to see how any mechanical clip can give equal security without adding to the effective diameter of the wire on the arc in contact with the wheel. The use of wire of figure 8, or grooved section, makes the mechanical ear satisfactory, but such wire is at once more expensive and more troublesome to erect, so that the balance of advantage remains with the soldered ear. The metal used for ears should be a tough bronze or gunmetal, and careful inspection after machining is necessary to eliminate defective pieces, as the castings are somewhat apt to show blowholes and other weak places. The groove to receive the trolley wire should be milled to a hundredth of an inch larger diameter than the wire, and should come to a sharp edge. It is doubtful whether the small lugs, which it is usual to provide at the ends of the ears for hammering over the wire, serve any useful purpose. They sometimes hold up a wire that has not been properly soldered until traffic commences. Fifteen inches is the minimum length of ear for straight work. The tendency is to increase the length up to as much as 24in., but the advantage seems doubtful. On curves longer ears are necessary, and by bending them to a proper radius the change of direction of the trolley wheel is much smoothed. Unfortunately, curved ears tend to pull into angular shape with use. There seems no good reason why they should not be cast curved with lateral webs to impart stiffness. It would not be necessary to use many different radii, as the varying radii of the track curves should be met by the use of a larger or smaller number of pull-offs, with a standard deviation at each. Splicing ears should not be

Digitized by Google

needed in building a new line, but are necessary for repair work. They are rarely well designed, the wire ends having to be bent too sharply, and some patterns are provided with foolish little steel set screws, that invariably set fast and break off. Anchor ears should be provided with stout eyes of rounded section, to which the anchor wire can be secured without bending to a dangerously small radius.

Section insulators present a combination of difficulties, and in selecting a pattern both mechanical and electrical considerations must be studied. The pull of the wires has necessarily to be transmitted through insulating material, and it ought to be so transmitted as a straight pull without any binding or twisting component. This is inconsistent with the necessity for allowing a straight level path for the trolley wheel. Hence the best designs are but compromises, and the worst may be guaranteed to break down within a few months. The terminating arrangements for the wire ends need the same easy curvature as in splicing ears. It is better to dispense with set screws for securing either the feeder cable or the trolley wires and to have tinned sockets or grooves into which they can be soldered. The air-gap pattern is probably better than that with a gap stick, but there should be two distinct air-gaps, and an insulated running piece between them to prevent an arc being drawn in the event of an earth on one wire. Gap sticks of lignum vitæ have been found to wear smoothly and give a regular life. Section insulators are very heavy, and saving of weight is a merit to be fully credited. Easy and rapid replacement is another virtue which will be appreciated when the line is at work. The sweating of the connections is not inimical to this, because, knowing that it has to be done, the fire-pot and bit will be ready, but a rusted-in set screw cannot be calculated for.

Junction special work fittings also require careful selection. For central wires and rigid trolley heads the frog makes a satisfactory facing point, provided that it is properly set with reference to the track points and the lengths of the cars and trolley booms. Even with swivelling trolley heads frogs will work fairly well if the wire is approximately central, but for sides wires, switches with movable tongues should always be used in the facing direction. Frogs will work on side wires in the trailing direction, but must have deep cheeks and grooves to take the wheel flanges, as there is a considerable centrifugal force tending to de-wiring, and automatic or spring switches are preferable. Crossings are apt to give more trouble than frogs or switches. The greatest care should be taken to get them of the correct angle to suit the track crossing, but as the angle is also affected by the lengths of car and trolley boom, the junction should be drawn to scale, a template of the car and trolley boom fitted to it in successive positions to ascertain the best angle and position for the crossing. Even with a central wire there must be a lateral pressure on the trolley wheel taking the junction curve, so that guidance by the flanges across the gap is necessary. A swivelling trolley head adds largely to trouble at crossing by its liability to turn while crossing the gap, and this liability is aggravated by any considerable side reach. At junctions on single lines it is best to use only a single trolley wire and thus avoid the use of crossings, especially if swivelling heads and side wires are used. It involves the use of three automatic switches, but these give much less trouble than one crossing. All these fittings should be so designed that the trolley wires need not be cut when fixing them, and so that they can be securely held by pull-off and span wires to their positions.

Feeding arrangements are usually classed with the overhead equipment, the feeder work terminating with the thimbles entering the 'bus-bar terminals. As regards the feeder pillars, the best advice is to make them as big as will be tolerated. Even at this they are pretty sure to be awkwardly cramped. Opinions and practice are divided between cylindrical and rectangular shapes. Perhaps it is largely a matter of taste. The cylindrical pattern gives the largest amount of useful space for the area covered and for the weight of the casting, and has the practical advantage that when opened the panel is somewhat more accessible. On the other hand, the fitting of the curved doors is not so good a job as with the flat-sided pillar, and when the doors are closed there is less clearance between them and the live parts. Provision should be made for ventilating the pillars without permitting the entrance of rain or snow; the bottoms should be filled in over the concrete with a thick layer of pitch or bitumen, and all leading-in pipes stoppered. The safest kind of panel is a cast-iron frame, into which are cemented porcelain insulators carrying the live metal-work, the frame being itself carried from the sides of the pillar by oil insulators. It should be easily removed for replacement by a new panel. All the cable connections should be made on one side of the panel, the switch fittings being on the other. Plain quick-break switches are frequently used and answer most purposes, but, where a number of feeder pillars are fed by one cable feeder, the use of switch fuses, such as the Bates pattern, will sometimes isolate a faulty length of trolley wire and avoid the stoppage of all the sections served by the feeder. As these switch fuses are not dearer than quick-break knife switches, and have no troubles of their own, they should be chosen, although in most cases the feeder circuit breaker will outstrip the fuse.

All cable ends should be terminated with corrugated porcelain stoppers suitably sealing the dielectric. A kicking coil and lightning arrester are necessary to protect the underground cables. Three or four kinds of arresters are in use, and there is not much to choose between them. I think the Garton is perhaps the best. They all get blown to pieces occasionally, either by a lightning discharge or the short set up by it. Telephone fittings are generally included in feeder pillars. They should not be fixed on the switch panel, but quite separately, and surrounded by an earthed metallic frame to protect them from leakage. The same treatment is best for the pilot wire terminals that may be provided. Telephones do not thrive in feeder pillars, and there is rarely any room for them. The provision of a socket box into which the cords of a portable set may be plugged is therefore the best arrangement. If fixed telephones are thought essential they should be placed in separate pillars, or in boxes secured to the poles. The side feed cables from the feeder pillars to the trolley wires are often troublesome; the trying conditions and their importance are such as to warrant careful design and erection. In many cases small holes are drilled through the pole underground and above the span-wire or bracket attachments, and the unfortunate cables threaded through these holes with the slight protection of a wooden or fibre bush. It is impossible to tell how sharply they may be bent, or how much they may have been strained in the process, but experience shows that they are frequently damaged, and have in consequence but a short life. Their replacement, in case of need, is a particularly tedious and exasperating job. The following has been found a good method of dealing with this matter. An oval hole about 3in. by 5in. is cut in one side of the pole about 1ft. below the ground level, and a special quarter bend of 3in. pipe passed into the pole and bolted through a flange which fits its periphery. This 3in. pipe finishes in the base of the feeder pillar, with a bellmouth providing a duct of ample diameter and easy curvature for the passage of the four cables. The pole is fitted with a special finial made in two parts. The lower part fits easily into the top of the pole supported by a narrow flange resting on the pole end, and expanding upwards and outwards to form the ornamental base collar of the finial. The portion inside the pole carries four screwed glands provided with rubber gaskets, and bored to pass the cable. Screwing up the glands secures the cables by compressing the rubber packing rings. Four holes are cored out in two opposite pairs through the bottom of the flared-out part, through which the cables descend outside the pole. This fitting is wired by passing the four cable lengths through the glands, and then, by an easy and regular curve, through the holes in the wide part. A hauling wire having been threaded down the pole and into the section pillar, the long ends are drawn through the pole, and the fitting rests on its place. The upper part of the finial is merely a cover shaped to match the other pole finials, and secured by two tap bolts. The outside cables are secured to the pole by a suitable clamp, and then taken by an easy curve to the span wire or bracket. This arrangement is safe for the cables, and, in case of need, their replacement is a very

Digitized by Google

simple and speedy operation. It is almost essential to use indiarubber-insulated cable, as the dielectric must be waterproof and flexible. The Board of Trade calls for metallic sheathing, but objects to lead in this position. Flexible metallic tubing has been found very suitable. It adds little to the diameter and weight; it is very flexible up to a certain point, and then refuses to bend further, which is a safeguard to the cable. The metal sheathing of the cable should not touch the trolley span or bowstring wire, and should therefore be cut well back. On span-wire work it is best to carry the feeder cables on a separate span wire above the trolley wires. This should be insulated in the usual way, and the sheathing cut back from it. The cable ends then dip down very conveniently to the section insulators, and there is a long surface of cable covering free in air, over which very little leakage can occur. The cable terminals here should be made with corrugated porcelain stoppers as a further precaution. On bracket arms the cables should be secured by special collars fitted with ebonite bushes, and arranged to give the longest possible leakage path.

Guard wiring is a necessary evil in this country, as tramway undertakers can neither compel the owners of overhead wires to make alterations to them, or even prevent the erection of new wires over an existing trolley line. Galvanised steel wire, No. 8 standard gauge, satisfies the requirements. Solid wire is better than stranded, having a longer life. The same wire may be used for guard-wire spans. Guard wires should be run over the span wires and secured to them by binding wire sweated at the ends of the lappings. In some atmospheres it is necessary to use bronze instead of steel wire. On bracket-arm work a span wire from the pole to a standard clamped to the end of the bracket makes the best job, but a neat and good-looking arrangement is hard to find. Secure erection is often neglected for the sake of light or ornamental appearance, with sad results. Telephone and pilot wires are sometimes run on tramway poles; hard-drawn copper is the best material. Good telegraph practice should be followed in the design and attachment of the insulators, but a somewhat freer use of shackles is sometimes desirable. These wires are sometimes carried on the trolley or guard-wire span wires, but it is difficult to make a good job of this. No. 12 wire is usually large enough; smaller sizes are too weak. They should be carried at such levels and positions that they cannot blow across the trolley wires if broken in a gale. The speaking on these telephone lines would be improved if they were rotated after the manner of Post Office trunk lines. They generally suffer much from trolley wire induction. Overhead feeders have sometimes to be provided for. They have to be carried from suspender wires, and to be covered, best done by hard cotton or hemp braiding saturated with waterproof preservative compound. These conductors should be shackled off at every pole. If they are large, it will be necessary to increase the size and stiffness of the poles used. As regards appearance such feeders are very objectionable, and they complicate the overhead engineering considerably, especially at feeder poles. But the saving of underground work is ofttimes an important economy, and a perfectly good job can be made.

Time and space limit this discussion to matters of material. Much might be said on erection, but I have probably said quite enough for one time. There must be now a good deal of information available as to the normal life of various items of overhead equipment under various conditions of traffic and atmosphere, and also as to the nature and frequency of breakdowns. Mr. McElroy last year made a laudable attempt to collect some of this information, and I am considerably indebted to the paper which he prepared for the last conference of the Municipal Tramways Association. This, however, is only a beginning and only partial, because, for some reason not easy to understand, no information was given to Mr. McElroy by any tramway company's officials. It is by the collation and discussion of information from all sources that advance may be expected, and every little helps, so the continuation of Mr. McElroy's good start is highly desirable. The cost of overhead work seems to vary a good deal more than it should. Some authorities put it at £1,500 to £2,000 per mile of route, but I don't know how so much can be properly spent. Thoroughly good span-wire work for either double or single lines can be erected for £1,200 per route mile, with fair profit to the contractor. Bracket-arm work for single lines, where a single line of poles is generally sufficient, can be done for £1,000 per route mile, or even less under specially favourable conditions. These rates include average amounts of guard wiring and proportion of junctions, but very heavy and complex junctions, car-shed fanwork, and similar special requirements will involve some additional expense. A great deal of money can be spent on elaborate scrollwork and fancy painting, especially if a little gold-leaf is thought necessary to harmonise with the surroundings; but these are matters of taste rather than engineering, and those who like to pay for them will doubtless continue to do so. In some towns there certainly is the excuse that the overhead structure is the only thing visible in the streets that bears the slightest trace of design or grace, of which the most should, therefore, be made.

## THE DISTRIBUTION OF ELECTRICAL POWER IN CITIES.

At a meeting of the Aberdeen Association of Civil Engineers on the 10th inst., a paper entitled "The Distribution of Electrical Power in Cities" was read by Mr. A. H. McKay, mains superintendent of the Aberdeen Corporation electricity department. The chair was occupied by Mr. George Mann, A.M.I C.E.

In dealing with the subject, Mr. McKay first described the general principles involved in designing a direct-current low-tension system of electrical distribution, explaining the appropriate applications of both the "two-wire system" and "three-wire system," and the necessity for a methodical use of feeders from the generating station to the distributing mains to ensure that the pressure is kept constant throughout the system. On this, he stated, the success of an electrical distributing system largely depended. The success and economy attending the introduction of increased voltage was next explained, the lecturer stating that at one time electric lamps could only be got for a pressure of 100 volts, whereas to-day they could now be had for any pressure up to 250 volts. With regard to the mains themselves, Mr. McKay explained that some systems of bare copper strip were first used with a certain amount of success, but that with the introduction of higher pressures they proved defective owing to the difficulty of getting proper insulation. After explaining other methods in use, he stated that the most satisfactory system of mains was that in which the cables were laid solid in a wooden trough about 2ft. deep.

Mr. McKay next stated that on account of the great expense of opening up streets for additional cables and the annoyance caused to city traffic, the great demand for electrical energy led supply authorities to consider the advisability of constructing subways for carrying cables. In the city of Aberdeen two such subways have been constructed, in which the feeder cables for both tramways and lighting are carried. They are such that when filled with cables a person can walk through their entire length and have the whole of the cables completely in view for examination. Altogether 1,500 yards of subway have been constructed in Aberdeen.

This most interesting paper was concluded by some very valuable practical remarks on the faults met with in an electrical system, their causes, location, and elimination. The paper was thoroughly well illustrated by sheets of hand diagrams and a fine collection of electrical apparatus, pertaining to the points introduced in the lecture.

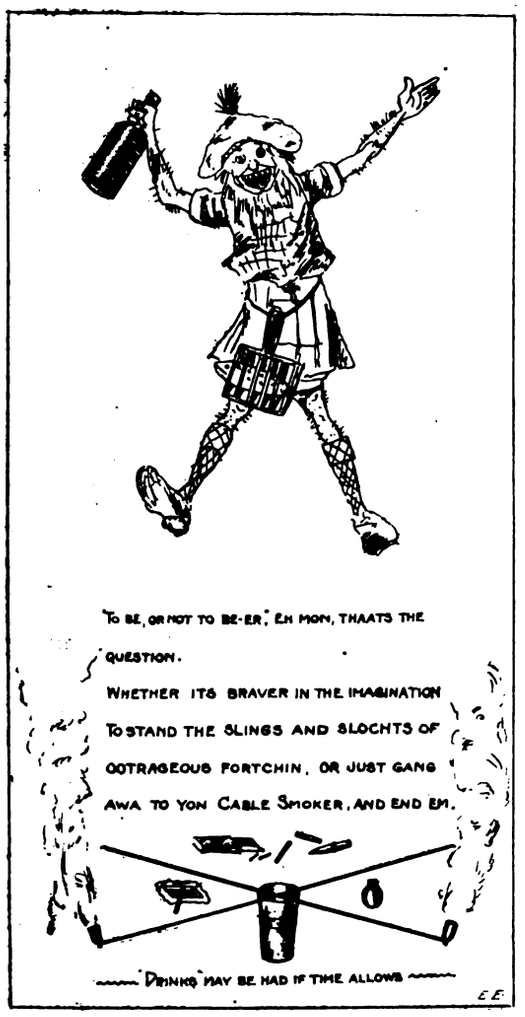
The discussion was opened by Mr. Bell, city electrical engineer, who congratulated the author on the manner in which he had presented the paper to the members, and referred to the abnormal advance of electricity in 20 years. The explosions in Aberdeen at electrical manholes, he said, were, through an interesting series of experiments, traced to the dissipation of electricity from the mains causing the air to expand, and produce the accident. The discussion was continued by Messrs. Milne, Cook, Moncur, Conway,

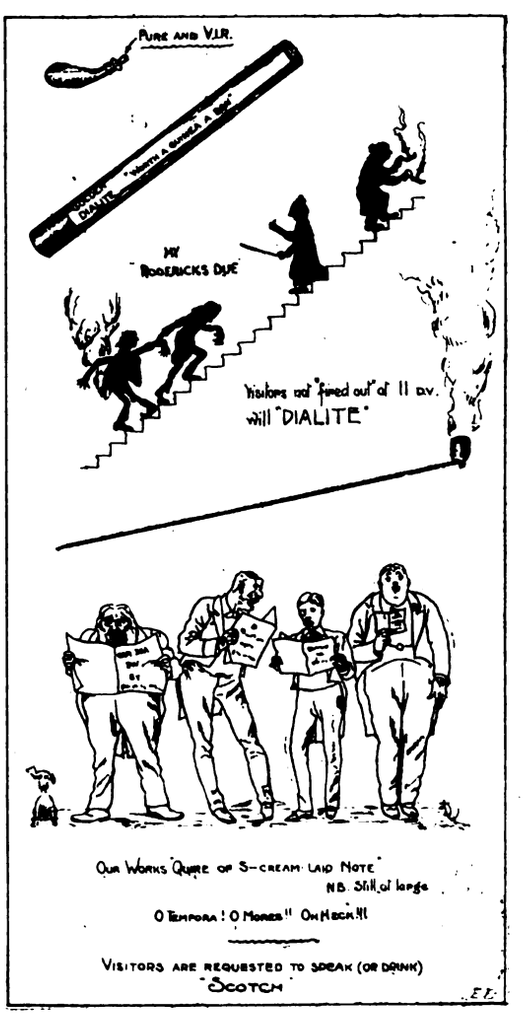
Digitized by Google

and Simpson, and, on the chairman's concluding remarks, a vote of thanks, proposed by Mr. Moncur, vice-president, and seconded by Mr. Conway, vice-president, was cordially awarded Mr. McKay for his most interesting paper.

## THE ST. HELENS CABLE COMPANY'S SMOKING CONCERT.

The first annual smoker of the staff of the St. Helens Cable Company was held on Friday at the Patten Arms Hotel. Mr. Kenyon was to have taken the chair, but was unfortunately prevented from doing so by indisposition. A most enjoyable programme of music was arranged, a good feature being that all the contributors were members of the St. Helens Cable Company's staff. The drawing office of this company was responsible for the invitation card, which is a work of high art. We reproduce herewith





two pages of this invitation card, which will show the extensive experience of the artist on other subjects than working drawings of cables and accessories. Due to the success of the first smoker, these functions are likely to become annual affairs.

## GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The monthly meeting of this section was held on Jan. 10, when Mr. H. B. Maxwell read a paper on "Street-Lighting by Electric Arc Lamps." Mr. Maxwell said that the objects of his paper were to show that street-lighting by electric arc lamps was not the expensive luxury it was generally imagined to be, and also to start a discussion which could not but be beneficial. The chief requirement of effective street-lighting was an illuminant which would efficiently illuminate the street without dazzling the eye, and at the same time give a maximum candle-power at an angle below the horizontal. The author contended that arc lamps met this requirement more fully than incandescent gas lanterns. In certain streets in Partick, six 3ft. incandescent burners had been displaced by each 12½-ampere arc. With the gas lamps, objects between lamps were indistinct at a distance of 100 yards from the point of light, while with the arc lamps similar objects were quite clear 300 yards distant in straight streets. The chief reasons why station engineers had not more arc lamps in circuit were: first, they failed to realise that street-lighting had a load factor of over 42 per cent., and consequently they did not charge low enough rates; and second, there was an inclination to cram too many lamps into the space available, instead of rather trying to place the lamps in the most suitable positions with a view to further extensions. The author thought the open type of arc lamp was to be preferred for street-lighting, as it was cheaper to maintain, and the colour of the light was better. Ten open-type lamps could be run in series as against five of the enclosed type. He preferred the use of large-sized lamps placed further apart to the adoption of smaller sized ones for the lighting of side streets. This meant that the lamps throughout were of a uniform size, and necessitated only one stock of carbons and stores being kept. He thought that the 10-ampere open-type arc lamp pendant from a swan-neck or bracket at a height of 20ft. would be found most satisfactory for all streets. In view of the fact that the cost of the lamp was only a small part of the total capital expenditure, it was advisable to get lamps of the best make, thus lessening the cost of maintenance and reducing the number of failures. In busy streets he would place the lamps 60 to 80 yards apart to suit the corners, and in less-frequented streets from 90 to 100 yards apart. A street lit with lamps staggered on alternate sides was better lit than with centre poles, and obstructed street traffic less. The use of tramway poles was not advisable, owing to the increased cost of maintenance as the result of vibration. With regard to ladders as against lowering gear for cleaning and trimming the lamps, the author was in favour of the former, for the reasons that the first cost was less, the maintenance cost of lowering gear was higher, a

Digitized by Google

trimmer could attend to at least as many lamps with the one as the other, and the ladder was probably the safer of the two in windy weather. The author was strongly of opinion that it was most necessary to control the street arc circuits direct from the station. This brought the street-lighting under the direct observation of the station staff, it obviated interference with street-lighting in the event of failure through faults developing in a distributor, and the extra capital charges were very much the same in the one case as the extra cost of wages and current in the other.

Mr. Maxwell gave some interesting data with regard to the price of street-lighting. From a table of costs he showed that the charges on capital and for current form over 80 per cent. of the total cost of the lamp if 1d. per unit is charged for current. It was, therefore, in these two items that any reduction in price must be sought. The 7 per cent. allowed for interest, sinking fund, and depreciation would be found more than sufficient. It was advisable to trim full during the summer months, as then half the trimmers could be put to other work. He found that one trimmer could attend to 90 lamps in Partick, but this figure he believed could be exceeded in other towns where the lamps were not at such a height from the ground, and the use of the telescope ladder was not therefore necessary. Every £50 increase in the total wages bill on a 400-lamp installation meant an increase of cost amounting to 2s. 6d. per lamp per annum. With regard to the charge for current, the only items which should be included were the works costs, minus wages (not increased by street-lighting load) and interest, sinking fund, and depreciation on capital cost of extra station plant except switchboards, which, together with cables and feeders, had already been debited against street-lighting capital cost. The increased cost for station plant would therefore be amply covered at £40 per kilowatt demanded. This charge on 400 lamps burning 3,500 hours per annum makes the cost per unit generated ·25d. + works costs, which in 54 stations mentioned in an *Electrical Times'* record brought the total cost per unit out at from ·57d. to 1d. Comparing this with the figure of £6. 15s., which is the average cost per lamp per annum of incandescent gas lamps containing three 3½ft. to 4ft. burners giving 100 c.p. after 50 hours' use, leads Mr. Maxwell to conclude that a very large number of towns can light their streets with arc lamps as cheaply as with incandescent gas, and with a large increase of light.

The remainder of Mr. Maxwell's remarks consisted of a description of the street-lighting scheme which has been carried out in Partick. The lamps are of the 12½-ampere size, and are 290 in number. In several streets they are placed apart as far as 180 yards. The circuits are run with $^{7}/_{16}$ twin lead-covered wires laid solid, the two conductors being insulated with different coloured papers, so that they may be distinguished. Contiguous lamps are connected alternately on the red and white conductors. The circuits have been run in this manner as far as possible, so that every alternate lamp only is out when a fuse blows. The circuits are run from feeder pillars, each controlling four to six circuits, supplied from the station by independent feeders and from separate 'bus bars.

"The street-lighting is started on separate machines from the ordinary supply, and afterwards paralleled on to the main bars, thus obviating any irregularity in the ordinary lighting due to switching on several circuits at once. As the machines are separated out again at dawn and shut down on the load, the feeder switches are only operated in the case of emergency, which is a great saving to the switches, as the arc formed when opening arc circuits on 500 volts is excessive owing to induction. Also, if an arc circuit or feeder is earthed so that a fuse will not hold, all that is necessary is to open the paralleling switch and run with one pole earthed till the fault is remedied. If the earth is on a circuit, it can then be easily isolated by testing at each lamp to earth with a voltmeter."

Efficiency and economy are provided for by a system whereby each lamp is thoroughly cleaned once a week, and a substantial bonus is awarded to the trimmer who shows the lowest costs per lamp per annum. The revenue from current also for the 300 street arc lamps in Partick is about £3,000 per annum, while the money spent on the scheme for goods manufactured in this country has been £18,000.

The following is an abstract of the discussion which took place:

**Mr. F. A. Newington** (Edinburgh) said that for side streets they had not at present any electric lamp which could successfully compete with the gas mantle. Where he had displaced gas with electric street-lighting it had been at the rate of three gas lamps displaced by one arc, as against Mr. Maxwell's six gas lamps to one arc. He did not think it was advisable to have all the arcs of one size and type. Such a proceeding would block the march of improvement. He was of opinion that something still required to be done with regard to the density of the arc-lamp globe. The opalescent globe meant a loss of about 50 per cent. of the light. He was averse to the use of lowering gear in windy places, as breakages of globes were likely to be frequent in the lowering and raising of the lamps. Mr. Maxwell's contention for separate feeders, etc., would, of course, entail extra cost, and it was significant that the Partick cost was £60 per lamp, whereas the average elsewhere was £30 per lamp. He should like the kind of ladder Mr. Maxwell used, which could be managed by one man. He disagreed with the author in his omission of wages from the costs given in the paper. The costs for arc lighting in Edinburgh were £10. 16s. 1d. per lamp per annum.

**Mr. Andrew Jamieson** said that the extreme distance of 150 to 300 yards was too much between arc lamps even in quiet streets, and he also thought that 15 guineas would be nearer the proper charge per lamp per annum than the figure given in the paper.

**Mr. Hanson** said he believed in the use of smaller lamps in quiet streets rather than large lamps placed further apart. He thought that centre poles could be used with advantage in wide thoroughfares, as they helped to regulate rather than hinder the traffic.

**Mr. Burbridge** said that he used lowering gear in Kilmarnock, and it worked very well. They had had no breakages with it, although the weather had been very windy. The lamps sometimes stuck, however, when half lowered, and then the ladder had to be brought into use. One man could trim 50 lamps comfortably in five hours in that way.

**Mr. Robertson** had a word to say in defence of the enclosed arc, which he said in its improved form was to be preferred for the lighting of quiet streets. From a recent estimate which he got out, he was driven to the conclusion that for the lighting of outlying streets gas was the cheaper illuminant. He thought Mr. Maxwell was quite wrong in omitting the item of wages from his estimate. Additional load in any large quantity was bound to materially affect the wages bill of the generating station.

**Mr. Wilson**, manager of Glasgow gas department, was present by invitation, and delivered a long speech condemning Mr. Maxwell's figures as inaccurate and only meant for "home consumption." Arc lighting had lost favour in the eyes of nearly all local authorities, while incandescent gas was extending everywhere. He maintained that Mr. Maxwell was selling his current for street-lighting under cost. While he was inspecting the lighting of Brighton, the electrical engineer who was showing them round lost his way, and someone suggested lighting a match, as the street was so dark—a fact! The speaker expected there was a good trade done in Partick in the match business.

**Mr. W. W. Lackie** thought Mr. Maxwell's street arc lighting load factor of 42 per cent. was too high, and that 30 per cent. would be more like the average. The distance apart, and not the candle-power, should regulate the height of the arc from the ground. He did not agree that arc lamps suffered by being put on tramway poles. He agreed with the author that ladders were preferable to lowering gear, especially in the central district of a city. As the capital cost was one of the chief items in street-lighting, he thought that more consideration should be given by engineers to high-tension continuous current, the adoption of which would be bound to lower capital cost.

The discussion at this point was adjourned till next meeting.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following is a summary of the resumed discussion on Mr. W. P. Adams's paper, entitled "The Combination of Dust Destructors and Electricity Works Economically Considered," of which a summary appeared in our issue of the 23rd ult.:

**Mr. H. N. Leask** had expected the paper to deal more with the planning of combined stations, as this matter deserved most attention when one was to be put down. A point which was apt to be lost sight of was that few combined works employ forced draught, which would facilitate economy and render the value of the destructor more apparent. An example was afforded by Mansfield, a small station generating about 1,500 units per day, where the refuse destructor was almost entirely relied upon. At that station over 50 units per ton of refuse are obtained, and on the peak load the figure has reached 120.

**Mr. W. R. Cooper** remarked that in the preliminary part of his paper the author had given the advantages rather than the disadvantages of destructors. One difficulty in combined works arose from the fact that the destructor had a full load as soon as it was built, but the electricity works started with a very small load. The result was that, initially, perhaps the whole of the steam might be supplied by the destructor. This stage soon passed when the electricity works became larger and coal firing had to be resorted to for parts of the load. Finally came the stage when separate boilers had to be put down to meet the load. All works were liable to pass through these three stages and eventually to find themselves with two lots of boilers. As the population did not increase as rapidly as the lighting load, the proportion of

Digitized by Google

steam supplied by the destructor became less, so that one had to consider how far it was worth while to complicate the system, and very possibly to use the coal to less advantage. The complication was apt to hamper extensions, and although there might be a gain in the first instance in the amount of ground required, this proportionate gain diminished as time went on. Moreover, the requirements of a station, as regards site, were generally incompatible with those of a destructor. A destructor should be placed well away from the best parts of a town, but if an electricity works was so placed there was likely to be a material loss in distribution. A chimney shaft might be saved to some extent by the combination, but it could be said that a whole chimney was so saved, because a destructor chimney was very large in proportion to the power which it represents. Mr. Cooper regretted that the author had taken for his basis *units* generated per ton. Since the efficiency from boiler to generator terminals varied very much from station to station, such a basis rendered any comparison of the different stations quite impossible, and there was no reason to hope that good results would be obtained at one station merely because they were obtained at another. The utilisation of the steam in the two cases might be quite different. The only true basis of comparison for destructors was the heat available from the destructor. This, however, was somewhat impracticable, and the next best basis was the quantity of steam raised per ton of refuse burnt. As to what was done with the steam afterwards, whether it was wasted or used to the best advantage, was a question of design and of the steam plant used. Referring to the various load curves, Mr. Cooper observed that these were generally complicated by the two quantities—coal and refuse; and in order to determine the effect of one of these quantities, the effect of the other had to be assumed. The curves in Figs. 20 and 24, however, which deal with refuse only, certainly gave valuable information. Fig. 20 refers to Hackney, and gives the high figure of 104·3 units per ton. This was accounted for by the economy of the station, and it had also to be borne in mind that stand-by losses with refuse did not exist, because the refuse was burnt whether required or not. Fig. 20 also gave a high figure—namely, 100 units per ton for part of the time—but in this case the calorific value of the refuse appeared to be unusually high. In the other curves the value of the refuse was apparently arrived at by taking an average value for the coal and calculating the value for the refuse by difference. The amount of fuel per hour was not directly proportional to the power, so that the figure for units due to coal should be increased, which meant that the figure for refuse should be lower. In any case, Mr. Cooper did not think that a comparison should be drawn between the effect of refuse and coal in a combined plant, because the coal was often burnt in such a station under disadvantageous circumstances. What was really important was the best that can be done with refuse as compared with coal under the best conditions. The author was inclined to look with scepticism upon calculations which depended upon refuse giving from 1lb. to 2lb. of steam per pound of refuse. The author would probably regard 1·5lb. as a high figure. Ordinary figures ranged from 1lb. to 1·5lb., and 1·25lb. per pound might, perhaps, be taken as an average figure. This is equivalent to 2,800lb. of steam per ton of refuse. If such a figure as 100 units per ton was to be obtained, it meant that the average steam consumption per unit generated for the whole station must be as low as 28lb., which was rarely found. The author's figures in regard to Fulham and Hackney seemed flattering to refuse, or did not do justice to coal. The criterion, however, must be the financial result. Unfortunately, it was always difficult to arrive at a sound conclusion from such tables as those given by the author, because the destructor and the electricity works were owned and worked by the same body. The combined undertaking was worked to benefit the destructor, not the electricity works, and the financial position was largely a matter of book-keeping. The only valid way of dealing with the matter was to consider the undertaking as a whole, and see whether the saving in fuel to the electricity works compensated the complication, with probably a lower efficiency, and a certain additional outlay for depreciation, etc.

**Mr. G. Watson** considered that managers of destructor works ought to be grateful to the author for his paper, though it was doubtless open to criticism upon matters of detail. He thought there was a danger of the Institution being formed into two rival camps—the enthusiasts, and those who threw cold water upon all these proposals. Mr. Highfield had spoken of refuse as though it consisted of nothing but malodorous fish and cabbage, but there were also cinders and the like, which rendered it a fairly good low-class fuel. It had also to be remembered that it was incumbent upon the local authority to dispose of the refuse in a sanitary manner, and this generally cost 2s. per ton where there was no destructor. Everybody agreed that the higher the temperature at which the refuse was burnt the more satisfactory the process, because you obtained more steam and better clinker. He thought that the modern destructor could be placed in the centre of any town, and the same considerations which prompted the placing of electricity stations in such positions applied to refuse destructors. He was not disposed to attach great weight to Mr. Cooper's point about the more rapid growth of the lighting load as compared with the population; when refuse destructors were designed, consideration should be given to future needs. Regarding the leakage of dust, some gentlemen seemed able to persuade themselves that dust would go through a 14in. wall. His experience was that if you put a wall between the power-house and the destructor, things would be all right. He agreed with Mr. Cooper's objection to the author's method of calculating the respective values of coal and refuse. Mr. Watson pointed out that the coal was burnt during a short period of high load, while for the rest of the 24 hours it was burnt in banked fires. A second lot of boilers might be obviated by using petroleum. Thermal storage had given good results at the Kensington and Knightsbridge works. No doubt as long as coal was plentiful, and electricity could command a reasonable price, low-class fuels would be neglected. He thought it would be found that the clinker which left the mechanical stokers in many large stations had calorific power to the extent of 5 to 7½ per cent., if not more, left in it. This would not only provide more fuel, but, if burned down, would reduce the clinker to a more convenient size. He thought these matters called for a more scientific attitude on the part of electrical engineers, who, however, could claim to be pioneers in the utilisation of refuse.

**Mr. J. H. Thwaite** regarded the total ultimate capacity of the Hackney plant—39,200 tons—as very low. He quite agreed with Mr. Watson's remarks concerning destructors generally, which were worked on a wrong principle in this country. They should be worked from an economical point of view, and if engineers would properly analyse the refuse they would obtain better results. The author was incorrect in saying that the only combined plant erected outside the United Kingdom was one in New Zealand. A station had been put up in Denmark, and gave results which surpassed expectations.

**Mr. L. Boot** recommended air-channel bars instead of ordinary solid bars for the grates, as he had found the former had a much longer life. Another point was the location of the economisers, which were sometimes placed in extraordinary positions. They should be put more in line with the flues. The dust problem was certainly an objection, as electrical engineers took a pride in their works. Mr. Watson's idea about a wall excluding dust took no account of skylights and other essential methods of ventilation. As to clinker disposal, it would be interesting to have particulars of the cost at Fulham for converting the clinker into bricks. The paper did not deal with the question, is it advisable to add destructors to existing electricity works? Mr. Boot did not think there would be much advantage where expense had to be incurred in putting down boilers, etc. He would like some figures in regard to the saving effected by thermal storage. There seemed to be a substantial discrepancy between the Hackney wages bill for the destructor and electricity works respectively, the former being heavily debited. With regard to accumulators, if manufacturers would bring out a suitable type, every engineer would no doubt use them, but at present he considered they were impracticable.

**Mr. Adams**, in reply, stated that the selection of refuse, which Mr. Highfield suggested was the reason for obtaining good results on the peak load, was out of the question in large works in London. He sympathised with engineers-in-charge in regard to the leakage of dust, but thought this trouble was overrated. In support of this he quoted from a paper read by Mr. Highfield before the Glasgow Section. He appealed to engineers to treat this branch of the subject from the point of view of utility, as the extra cost of repair to machinery was a negligible quantity compared with the value of the refuse. By "storage" he simply referred to the storage from day to day, as actually carried on in some works at the present time. He welcomed Mr. Russell's announcement that he was experimenting with a method of burning the fuel down to a lower point, as clinker-disposal was of the greatest importance. Mr. Adams had not any detailed figures to give in regard to the conversion of clinker into bricks at Fulham; but if the proceeds equalled the cost it represented a gain, the clinker being thus disposed of without expense. He hoped that the importance of keeping separate accounts would be recognised as it was at Hackney. Hitherto the electricity works had generally been favoured when apportioning the expenses. He thought the method he had adopted in calculating the capital charges was quite justified. In regard to the calculation of Prof. Forbes, to which reference was made in the paper, it only applied to private lighting. Mr. Russell objected to "units per ton" being taken as the criterion of the value of the destructor works, but where so many factors entered into the question it was impossible to devise a perfect method of calculation. Diagram 3 and Tables 7 and 9, however, furnished a considerable amount of supplementary information upon this point. A good deal of criticism had been directed against his estimate that 100 units per ton of refuse should be practicable, but this result was actually being obtained, notably at Woolwich. Test figures were not always representative of a plant's capabilities, as the furnaces were quite cold in the first instance, but after getting into working order better results might be secured. He thought the figures he had assumed for the peak values were quite fair. The figures given in the curves were necessarily approximate to some extent, but they were substantially correct. In regard to the values he had taken on the peak for coal, at Hackney the average value was the peak value, as banking did not enter into the question. The case of Fulham was not quite so simple, but, generally speaking, there was not much difference between the average and the peak value. Respecting the water consumption at Fulham, the figure of 59lb. given in the paper was that derived from a test, but no doubt better results could be obtained. It was a question of evaporation. In further support of his estimate, that 100 units per ton of refuse were obtainable, Mr. Adams quoted some recent figures from Partick.

A vote of thanks was unanimously accorded to the author.

## PERSONAL.

Mr. G. R. Pepper has been appointed to the position of head of the publicity department at Croydon works.

Mr. M. Farrar has resigned the position of chief assistant to the Twickenham and Teddington Electric Supply Company to take up the position of resident engineer to the Ramsgate and District Electric Supply Company.

Mr. H. H. Oxley, of Lincoln, has been appointed junior assistant at King's Lynn electricity works.

We are informed that Mr. Thomas Thomas, of Ogmore Vale, Glamorgan, has been appointed by the Bridgend Urban District Council as working electrician. In response to an advertisement in our columns, 325 persons applied for list of duties, and there were 143 applications for the position.

## SINKING FUND INSTALMENTS.

We should not have touched this topic at present had not our contemporary, the *Accountant*, incited our curiosity, and now we want badly to ask questions and receive enlightenment. The *Accountant* is expert in all that concerns accounts and the funniosities therein, but its dicta are often outside the comprehension of the non-expert. The misfortune is that these experts so often in their statements put in a saving word or clause, so that the interpretation is rendered more difficult. Here is one sentence taken from our contemporary which puzzles us: "It has been so frequently assumed that loans sanctioned by the Local Government Board for trading purposes are fixed for a period approximating closely with the estimated life of the assets that will be acquired, that it seems desirable to draw attention to the fallacy of any such assumption." Now, what does that mean? That there is no connection with the loan granted and the life of the work for which it is granted, or what? Is the fallacy in "approximating closely," or is "closely" merely the saving word? Does the Local Government Board toss up as to how many years a loan should run, or has it some system other than "life of work" about which the public knows nothing and evidently cares less. We seem to have heard that a short time ago the period for loans for wood paving was in certain cases shortened because experience showed that the paving did not last as long as it was expected to last. Was it wrong to assume, then, that life of assets had something to do with the period of such loans? However, we are anxious to learn, and shall be under a deep debt of obligation to our contemporary if it will give us a real insight into the procedure of the Local Government Board with regard to period of loans. Its example does not help us far, because it is merely a comparison between the procedure of the London County Council and the Local Government Board. For electricity expenditure the London County Council's equated term is forty-two years; for the country that is under the Local Government Board's *régime* it is twenty-five years. If we might assume anything, it would be that the Local Government Board, feeling a certain responsibility, wishes to be on the safe side, while the London County Council is willing to run close to the wind—or, rather, to the "life of the asset." We have a more or less vivid recollection that Mr. Snell, of Sunderland, a past-president of the Municipal Electrical Association, has made a special study of this "equated time," and that his views are corroborative of the London County Council's action. It may be that neither of these periods is settled with any regard to life of assets, yet it can hardly be settled by chance.

Another sentence in our contemporary is very funny. What it really means we know not; but, then, it takes a sledge-hammer or a ton of dynamite to drive a joke into a Scotchman's head or to explain to him a conundrum. Here is the trouble: "That unduly extended periods for loans are no real economy, even at the time, seems to be shown by the fact that the charge at Poplar in respect of interest was £6,331 (3·26 per cent.) against £4,327 (2·97 per cent.) at Eastbourne." What is the use of a head if you cannot understand? Does the *Accountant* assume that in these cases rate of interest is directly as length of life of loan—hence Poplar having the longer period pays the greater rate of interest? If not, what on earth does it mean? In our benighted sphere of operations we should never have thought of connecting interest so closely with period of loan, but should have wondered at the state of the money market when the various loans were floated. Really, we live and learn, and if our expert con-

Digitized by Google

temporary can prove its case, that rate of interest varies directly with length of loan, the shorter the period the lower the rate of interest, it is a satisfactory argument for the Local Government Board in keeping its loan period short. We have always inclined to the opinion that "unduly extended periods" and unduly "contracted periods" for loans were equally bad. In the former there comes a time when, as in the case of wood paving, there are no assets against the outstanding portion of the loan, while in the latter case too great a burden is thrown upon the early users. Electrical engineers, so far as we have gathered their opinions, think too short a period, giving an unduly large sinking fund, accompanied, as it usually is, by biassed pressure for more depreciation and better upkeep, is in the nature of a calamity, putting far too great a strain upon an undertaking in its early years, mulcting too heavily its earlier users—all to the advantage of posterity, who have done nothing in the way of development, exploitation, and perfection. The old economic view of small profits and large returns is upset and progress retarded, for the profits must in the nature of the case be larger than if longer time was given for repayment. Our views are possibly absurd. We are open to conviction if our contemporary will assume we possess an open mind, and desire information easily to be digested or interpreted. The equated time of the Local Government Board may be—possibly is—too short, hence the weeping and wailing throughout the country and the jealousy of countrymen against the London County Council, whose time, on the other hand, may be too long, leading in the sweet by-and-by to many bad financial positions. The counsellors are multitudinous. When shall we obtain wisdom?

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### TELEPHONE RATES.

SIR,—I suppose that if it were argued in your columns that no hotel ought to charge more than 7s. 6d. a day for full board and lodging, and, therefore, that all hotels in Great Britain should be built, equipped, and run on the basis of such a maximum charge, the most casual reader would see the absurdity of the argument. Different people require different hotel accommodation, and pay accordingly. It is much the same with telephone service; different people take different classes and quantities of telephone service, and pay accordingly.

Mr. Alfred R. Bennett, in your issue of Jan. 6, says that the "business way" of dealing with the telephone service is to fix arbitrarily a flat rate of £5. 10s., and adjust the whole business to that. No more unbusinesslike way of attacking a telephone problem could possibly be imagined. It is more foolish even than putting the cart before the horse. It is picking out in advance a weedy animal to draw the cart without any regard to the style and size of the cart, the load to be carried, the road to be travelled, or the speed or length of the journey. It is precisely this haphazard and superficial manner of approaching the telephone business which has led the few British municipalities now engaged in telephony into the troubles they are now gradually realising.

The proper way to arrive at a commercial telephone tariff for any given city or area is to study in the greatest detail all the various conditions. Such a study is by no means a simple matter, as there are a great many factors to be considered. If proper consideration be not given to all the factors, trouble will inevitably arise. If a telephone scheme be launched without a thorough preliminary study, without due regard to modern telephone methods and on a narrow margin of possible profit, it will be a commercial failure before it is many years old.

The really important features of the telephone business are an efficient service and high development. An essential feature of any business is that it shall pay. Give the public an efficient service, develop it broadly so that it shall be generally useful, and the public will cheerfully meet the rates necessary to make it pay.

To seek to adjust the whole telephone business—a business in which the requirements of individual customers vary between wide limits—to a rate for a single class of service, and that rate arrived at by pure guesswork, is a proposal which is not only narrow-minded and unscientific, but is flatly at variance with practical experience.

The effort to work to such a proposal results in subordinating every consideration to that of cheapness. No more certain way of ensuring the ultimate failure of a technical business could be devised. The municipalities in this country which have so far engaged in telephony have proceeded on Mr. Bennett's plan of fixing arbitrarily a low flat rate for unlimited service, and then seeking to adjust the whole business to that one rate. The result has been that the municipalities have provided themselves with badly-designed and badly-found telephone plants, which represent in the main the practice of 12 or 15 years ago, and will all have to be rebuilt in a few years.

The existing municipal systems seem to have been dropped down without any thorough study of the various factors of the problem, without any regard to the existing state of the telephone art, and without any regard to systematic future development. The result is that we find the municipalities struggling with call-wire systems, push-button systems, and indicator systems of various kinds, sometimes with a mixture of several systems in the same town, and extending haphazard and piecemeal with a total absence of a settled technical policy.

What is the actual situation in the only municipal telephone system having a history of over three years? At Glasgow the Telephone Committee is face to face with the necessity of rebuilding a plant which, for the most part, has been in service less than three years. It has been found impossible to give a satisfactory service with the mixture of call-wire and indicator plant laid out in 1901. The Glasgow system has cost per working subscriber's line (the unit on which the estimates were based) practically double the estimated cost. To put the plant abreast of modern practice will cost from a third to half as much again, even assuming that the cable and distributing plant is in sound condition. Therefore, if the Glasgow Corporation undertake an effective reconstruction of their telephone plant, they will have spent by the time the work is done nearly three times the capital per working subscriber's line which, by the process of working backwards from an arbitrary rate, was originally forecast. What then becomes of the £5. 5s. flat rate?

No more striking object lesson in the folly of dealing with a great technical business in the superficial manner advocated by Mr. Bennett could possibly be desired than the telephonic muddle at Glasgow.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, Westminster, S.W.

[What Mr. Webb writes is always interesting reading, but sometimes his advocacy leads him to do scant justice to his adversary. We certainly do not read Mr. Bennett's remarks in our issue of Jan. 6 last, or put the interpretation upon them that Mr. Webb does. Here is our interpretation:

1. Mr. Bennett is discussing purchase by the Government of the National Company's interests.
   As business men it is the duty of the National to get all it can, and of the Government to buy as low as it can.
2. Mr. Bennett says the Government is not good at making a bargain, and ought to be cautious, for
   It is shown by Continental and American practice that a rate of from £5 to £6 is remunerative, hence
3. In making such a purchase the Government ought to consider what maximum rate they can well ask from subscribers, and Mr. Bennett merely assumes £5. 10s. for argument's sake. He might have assumed £6. 10s. or £60. 10s, and his argument would have been unaltered.

Digitized by Google

4. The Government ought not to pay a single penny more than necessary, because any such extra payment means increase of tariff; yes, an unwarranted increase of tariff.
5. Mr Bennett goes on to say much capital will have to be expended to bring the purchase up to date. Mr. Webb's letter is largely saying that Mr. Bennett's work is not up to date.

Beginning with the third paragraph, Mr. Webb is dealing with a subject not touched upon by Mr. Bennett, his argument being directed to show how we ought to construct a commercial tariff, and a gibe at Mr. Bennett's (to him) lack of up-to-dateness. As we have said before, these experts may discuss each other's up-to-dateness till all is blue for what we care. We are only concerned at misinterpretations, because our interpretations are then criticised.—ED., *E. E.*]

## THE METRIC FALLACY.

SIR,—The communication from Lord Belhaven in your issue of Dec. 23, indicates that he is labouring under a misapprehension regarding the metric agitation in this country. He asks: "Is it generally known that America has so far departed from the British system of weights and measures as to adopt the metre as the fundamental standard of length, the yard being derived from such standard metre? Is this a part of the metric fallacy?" It is not only a part of the metric fallacy, but probably the weakest part of that house of cards.

In one of the Government bureaus at Washington there are two bars of metal—one called a yard, the other called a metre. In 1893, one of the metric scientists in the employ of the Government persuaded the Secretary of the Treasury Carlisle to issue an order that the bar called a yard should be "verified" by the lines on the bar called a metre, and since then the metricites have been shouting themselves hoarse that the fundamental standards of the United States are on a metric basis. The grotesque pretence that an employé of the Government could, by a stroke of his pen, change the fundamental linear standards of 80,000,000 people would not deserve refutation were it not that it is spread broadcast by the metricites, and leads many, as it has led Lord Belhaven, to believe that it means something. This metric fallacy recently received a new impetus by a letter from our Bureau of Standards to the British Consul-General at New York.

Unfortunately, the metricites do not always confine themselves to the vague expression "fundamental standards," which has deceived his lordship, but use the pretence as a basis for statements that can best be described by an Anglo-Saxon word of three letters. Thus, the Bureau of the American Republics—another Government bureau temporarily under the control of the metricites—states once a month in its *Bulletin* that "the metric system has been adopted in the United States of America." This *Bulletin* is published in English, French, and Spanish, and 12 times a year it carries this metric "fallacy" to every country on the Western Hemisphere, and such methods are deemed necessary to support a system that is claimed to make its own way because of its merits, and to be the only scientific system of weights and measures on earth.

Our Government officials may verify their yard bar by the lines on their metre bar, or their metre bar by the lines on their yard bar; or they may alternate such methods of verification so that our "fundamental standards" may be metric in the forenoon and English in the afternoon; but whatever they do or leave undone, the people of this country will continue without interruption to do business on the basis of the English system of weights and measures, and if ever they find it necessary to verify their fundamental yard stick, it will be done by the yard stick in London and not the metre stick at Paris. Lord Belhaven refers to the American Chamber of Commerce at Paris. This is a pro-metric association, and last year formulated and presented to the Société des Ingenieurs civils de France, another pro-metric organisation, a series of 30 questions. Although they are entirely *ex parte*, these questions and answers contain admissions extremely damaging to the metric cause.

The metrological anarchy unearthed in the Philippines is a conclusive answer to Lord Belhaven's argument that "If the custom house in a metric-using country requires all invoices to be made out in the metric system, it matters very little for purposes of our export trade what weights and measures prevail in the far interior of that country." The metric system has been used very little in the Philippines outside of the Government bureaus. Take the hemp industry, for example, whose products form by valuation nearly three quarters of all the exports of the islands. Locally, on the plantations and in transactions between dealers, Philippine hemp is always bought and sold by the Spanish *picul* and *arroba*. When the fibre reaches the custom house the invoices are reduced to kilos, and again (as in the case of 93 per cent. of the exports), when it is shipped to the United States or England, the invoices are reduced to pounds. The use of the metric system in the custom house thus necessitates two useless conversions of the weights (in each case from one incommensurable standard to another), and is a wholly unnecessary impediment to business.

The extract Lord Belhaven makes from the report of the Secretary of the Treasury simply means that our metricite officials have been presenting their fallacies to his (the Secretary's) attention. Weights and measures are regulated in the United States by Congress, and not by the Secretary of the Treasury. At present a Metric Bill is before the Committee on Coinage, Weights, and Measures, and it is stated on excellent authority that it has only one friend there, although the same committee reported a similar Bill favourably three years ago with but two dissenting votes out of a total of 18. The change has been brought about by discussion, during which the following associations have officially declared against the metric system: National Association of Manufacturers, American Society of Mechanical Engineers, American Iron and Steel Association, National Association of Carriage Builders, National Association of Heating Engineers and Contractors, Engine Builders' Association of the United States, National Association of Builders, National Brick Manufacturers' Association, National Association of Machine Tool Builders, Furniture Association of America, National Metal Trades Association, Association of Railway Master Mechanics, Master Car Builders' Association, American Society of Heating and Ventilating Engineers, Providence Society of Mechanical Engineers, and Society of Naval Architects and Marine Engineers.

Important as is the official action of these associations, it is but a zephyr to the cyclone of protest that would be raised in the United States if any administration should attempt to force the people to abandon the English standards of weight and measure. The population of the United States presents 80,000,000 reasons, and 4,000 new ones every morning, why the uniformity of measures between them and Great Britain should not be disturbed.—Yours, etc,

SAMUEL S. DALE.

Boston, Mass., Jan. 10, 1905.

---

SIR,—My attention has been drawn to the leader on "The Metric Fallacy" in your issue of Dec. 23, 1904, in which you remark, quoting from the British Weights and Measures Association pamphlet, "We are not aware of any single country in the world, not even France, that has made the metric system its textile standard."

As one of the members of the "Comité permanent des Congrès international de 1900 pour l'unification de numérotage des fils," I can safely say that the chief reason why the metric system in numbering yarns has not been universally adopted is that Great Britain has refused to agree. I myself, as representing the Leicester Chamber of Commerce at a meeting of the Associated Chambers of Commerce, proposed its adoption in Great Britain some years since, and met a considerable amount of support, but it was thought impracticable for this country until the metric system of weights and measures was the national system.

At the congress of 1900 held in the Paris Exhibition, the following countries unanimously supported the adoption of the metric numbering of yarns—namely, the number of thousand metres contained in a kilogramme: France, Belgium, Austria, Spain, Italy, Germany, United States, Sweden and Norway, Switzerland, Hungary, Luxembourg,

Digitized by Google

Japan, Mexico, Russia, Turkey; Great Britain being the only dissentient.

The French textile manufacturer is quite right in saying they are in anarchy, but it is not the fault of the French nation.

One result of the congress of 1900 at Paris has been the adoption by users and makers of raw and thrown silks, *including the Silk Association of Great Britain and Ireland*, of the metric numbering of silk for international purposes.

You speak of the persistence of old units in France, but in all commercial transactions and all book-keeping the metric system is in use. The word "livre," or pound of 500 grammes, is being replaced even in retail shop windows by "half kilo," and though a seller may quote a price of cent sous, in his invoice he marks the article five francs.

As a member of the executive committee of the Decimal Association, I should like to finish my letter by saying that although we advocate the decimal system of weights and measures on account of its international importance, we do so quite as much in the interests of internal trade, and simplification of education. I may also say that those who use decimals throughout, as in the metric countries, have many ways of abbreviating their calculations, quite as much as we have by the use of practice, etc., and have thus all the advantages, without the disadvantages, of compound arithmetic, which does not exist in the metric system.—Yours, etc., W. T. ROWLETT.

Newarke-street, Leicester, Jan. 16, 1905.

---

SIR,—Referring to Mr. Johnson's letter appearing in your issue of the 13th, he surely has a very poor opinion of British scientists and manufacturers when he states that it is impossible to reform our existing system by bringing about the inter-relation of the inch with the pound, which, he truly states, is the chief disadvantage our present system suffers from.

A man that has a defective machine does not throw it away if by a little alteration he can make it as effective—possibly superior—to some new machine which is recommended to him, especially if that machine has its own recognised defects; and this is what we should do, and what can be done, with our weights and measures. It is deplorable that Lord Kelvin and those who follow him should have so far agitated for the introduction of a new, expensive, yet imperfect, machine, instead of using their great abilities to perfect the existing one.

In view of the reintroduction of the obnoxious Metric Bill before Parliament in the coming session, it is of the greatest importance that the country give every possible support through its councils, corporations, societies, and individuals to this association in its efforts to bring about by easy and inexpensive means the results which are sought by the Decimal Association asking Parliament to impose upon us by most expensive, revolutionary, and compulsory methods.—Yours, etc., GEO. MOORES.

## FIRE-ALARMS.

SIR,—Can any reader inform me of a recently-erected and efficient fire-alarm and telephone system in a large public institution or asylum?—Yours, etc, INTERESTED.

[Our correspondent should write to the May-Oatway Fire Appliances, Limited, who make a speciality of this class of work.—ED. *E.E.*]

---

## CENTRAL STATIONS IN GERMANY.

The statistics for 1904 published in the *Elektrotechnische Zeitschrift* show good progress with central-station works in Germany during the year just passed. There are now 51 electricity works in the Fatherland, each having a plant capacity of 2,000 kw. and upwards. The aggregate output of these 51 stations, distributed among 33 towns, amounts to 290,693 kw. As regards individual stations, the Berliner Elektricitätswerke, Berlin, easily heads the list with a capacity of 85,136 kw., the six smaller works which help to serve the capital totalling another 83,185 kw. between them. Hamburg follows Berlin with six central plants, having a total capacity of 53,905 kw., of which 25,433 kw. is installed in one station. It is pointed out that there are at the present time 1,108 central electricity works in Germany, but of these only 1,028 are dealt with in the tables, since particulars relating to the remaining 80 were not forthcoming in time for publication. The 1,028 works included have a total output of 530,947 kw., accumulators representing 96,065 kw. of this, while the load consists of 5,687,382 50-watt incandescent lamps, 110,856 10-ampere arc lamps, and 263,036 h.p in motors—an aggregate of 576 529 kw. Compared with these figures we find that in 1894 there were 148 stations, with 493,801 50-watt incandescent lamps, 12,357 10-ampere arc lamps, and 5,635 h.p. in motors connected. As regards systems of supply, continuous-current plants working with accumulators largely predominate, numbering 803, with a total output of 245,220 kw. Mixed systems are installed in 79, polyphase in 63, alternating current (single and two phase) in 41, and continuous current without accumulators in 40 instances respectively. The large majority of the plants are driven either by steam or water power; but it is interesting to note that gas-engines are employed exclusively in 94 stations, having an aggregate output of 10,050 kw. The progress of the various power transmission schemes seems to have been fairly satisfactory. The Brühl station, opened in 1899, which supplies 66 townships and villages within a radius of 15 km. to 20 km. with current for lighting and power has plant aggregating 1,540 kw. installed, while the load connected consists of 22,272 50-watt incandescent lamps, 208 10-ampere arc lamps, and 1,975 h.p. in motors. It should be mentioned that the population within the area of supply is 66,000. Polyphase current having a frequency of 50 is generated at this station and transmitted at a pressure of 5,500 volts to the different centres of consumption, where it is transformed for distribution on the three-wire system at 115 or 230 volts. The two stations belonging to the Oberschl. Elektricitätswerke serve a population of 360,000. They have generating plant of 9,980 kw. total capacity installed, besides 622 kw. in accumulators. The load consists of 83,710 50-watt incandescent lamps, 2,516 10-ampere arc lamps, 5,217 h.p. in motors for industrial purposes, etc., and 5,797 kw. in tramway motors. Polyphase current having a frequency of 50 is generated and transmitted in this case at a pressure of 5,850 volts.

The better-known Rheinfelden station, wherein some 12,700 kw. of plant is installed, serves 46 townships and villages, the load connected consisting of 28,396 50-watt incandescent lamps, 164 10-ampere arc lamps, and 7,642 h.p. in motors. There are also a number of smaller transmission stations scattered about Germany. In sharp contrast with these are numerous small electricity works designed to supply current principally for power purposes locally, their erection being the outcome of co-operative efforts to stimulate home industry and benefit small users of power. The Anrath electricity works, near Crefeld, may be regarded as a typical illustration. All the motors receiving a supply from these works are of ¼ h.p. to ½ h.p. each. They are used in connection with the local ribbon industry, which is carried on largely in the homes of the workers.

In conclusion, reference may be made to a noteworthy change indicated by the returns published in the *Elektrotechnische Zeitschrift*. We allude to the rapid increase during the last few years in the consumption of current for general power purposes, and the comparative slackening in the increase of electric lighting. Thus, taking Berlin as an example we find that down to 1899 the kilowatt equivalent of the total lamps connected exceeded that of the motors installed, while last year a total equivalent of 36,195 kw. in lamps was connected as against 44,448 kw. in motors, exclusive of the tramways load. According to the returns there are now 12,933 electric motors installed in Berlin, apart from the tramways.

---

## TRADE NOTICES AND NOVELTIES.

### G. E. C. Progress.

The Progress Sheet issued by the General Electric Company, Limited, for the current month includes particulars of the

Digitized by Google

Angold automatic suspension gear and contact device. This apparatus consists primarily of a device for automatically holding the lamp and taking the strain of the steel wire; and, secondly, of an arrangement of contacts for conveying current to the lamp. It is suitable for any make of arc lamp. The accompanying illustration (Fig. 1) shows the apparatus with the clutch gear and contact plug out of the socket. The upper and larger portion is fastened to the lamp bracket or ceiling plate, while the inside plug is attached to the lamp top, being fitted with two spring-controlled catches, which are normally in a horizontal position. When the lamp is drawn up by the winch these catches first strike against the bell mouth of the socket, which depresses them inside the plug until the first increased diameter inside the socket is reached, when they open out and support the weight of the lamp. The suspension wire is now slack, and relieved of all strain. To lower the lamp, it is first pulled a little higher until the catches reach the second increased diameter of the socket, where they open out horizontally, and if the winch be released the lamp will come down and the catches will be thrown upwards as they pass the two steps in the socket, springing into the horizontal position, when they emerge from the well mouth.

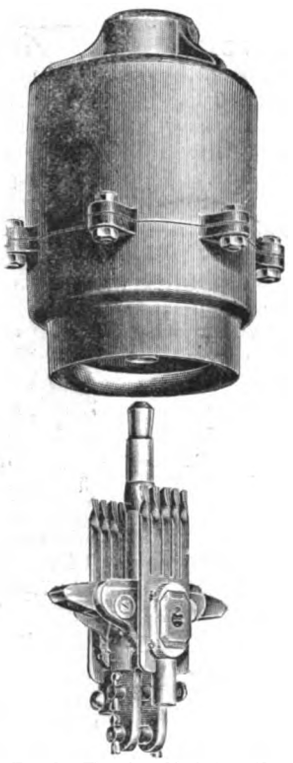

FIG. 1.—The Angold Automatic Suspension Gear and Contact Device.

Another item dealt with is the "Wigan" (patent) mining bell, which we are told has been specially designed by Lancashire mining experts to meet the requirements of the Government mining inspectors and colliery engineers. It is absolutely watertight and gas-proof. The whole of the electro-magnetic movement is enclosed in a cast-iron case. Either trembling or single stroke can be supplied, but on account of the quick action the trembling type is recommended for all ordinary installations. The coils of the trembling bell are wound to a resistance of 60 ohms, and those of the single-stroke bell to a resistance of 30 ohms. The accompanying diagram (Fig. 2) illustrates the essential features of this bell. The ordinary hammer, H, attached to the armature strikes against the subsidiary hammer, B, which is fixed immediately under the edge of the gong.

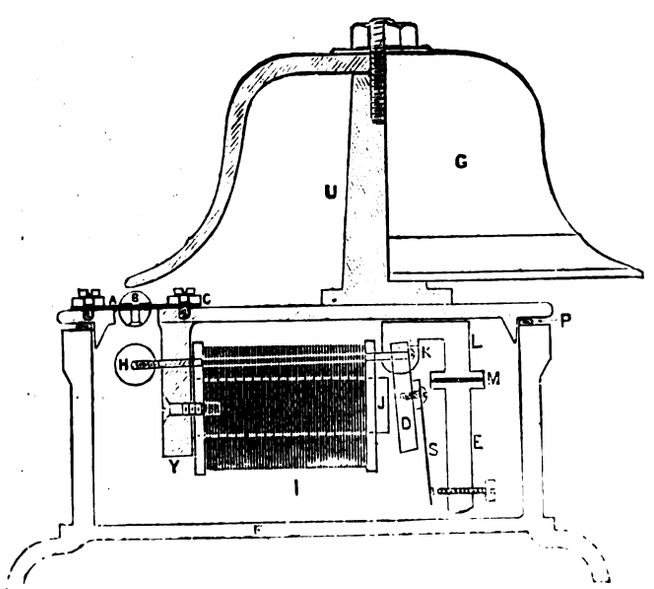

FIG. 2.—Diagram of the "Wigan" Mining Bell.

Alarm bells suitable for fire-alarms, factories, mines, and railways, etc., find place among the further contents of this sheet. These bells, we understand, are in considerable demand.

A separate circular gives particulars of the arrangements made by the company for the convenience of customers wishing to transact business by telephone. It seems they have provided their private branch telephone exchange with operators able to take down orders and messages in shorthand—a departure which will doubtless be widely appreciated.

## Simplex Price List, 1905.

In the seventh annual edition of the price-list issued by the Simplex Steel Conduit Company, Limited, of 80, Digbeth, Birmingham, and 20, Bucklersbury, London, E.C., there is much that merits praise. Thanks are expressed by the firm in the preface to those consulting and station engineers, architects, and electricians who have given them the benefit of their advice and experience in connection with the many improvements in Simplex fittings included in the catalogue. One of the secrets of the firm's great success is, no doubt, revealed by this action, since it proves their readiness to profit from the advice tendered by competent critics. Their policy is evidently to march with the times and to introduce improvements as the necessity arises or is suggested by practical experience. In this way the flexibility of their system has also been increased to meet new sets of conditions, until it may be said to satisfy all the requirements of to-day. So many interesting details are illustrated in the list that it is difficult to select for special notice the small number which limited space demands. However, we will do our best. The accompanying illustration (Fig. 1) shows an octagonal box. This box is supplied with an accurately fitting cast cover, with edges which overlap by $\frac{1}{8}$in., attached by three brass screws, and can be readily made watertight. It will take up to $\frac{7}{8}$in. screwed conduit fixed through clearing holes by lock-nuts, or $\frac{7}{8}$in. unscrewed conduit fixed by contact nipples. There are a variety of uses to which this box can be put—viz., as a bend, "T" piece, or inspection box of large capacity; for wiring down to lighting points through cement or patent floors with a centre hole for the down run, terminating in a bellmouth piece and block; as a X or Y inspection piece; or as a star box for lighting a number of points from a central position.

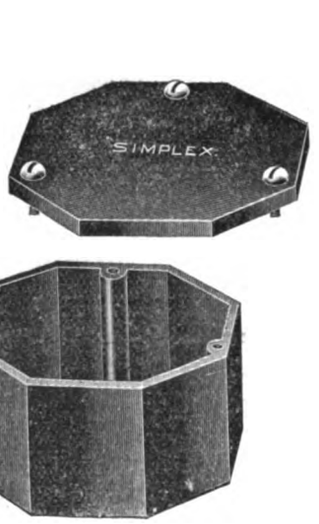

FIG. 1. Simplex Octagonal Box.

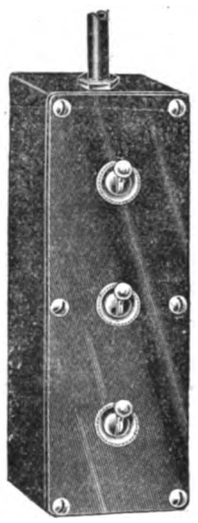

FIG. 2.—Simplex Multiple Switch Fitting.

It is often found necessary to group switches together. Our next illustration (Fig. 2) shows a convenient way of doing this in the case of three-way sunk switches. The switches may be mounted flush if preferred. The insulating cover of the light cast box is attached by brass screws, and can be readily removed for wiring or inspection purposes.

FIG. 3.—Simplex Insulating Bushes.

Conduit insulating bushes form one of the principal adjuncts to the Simplex system. These bushes are moulded under pressure to exact diameters in three patterns—namely, internal, external, and screwed—the first two of which are illustrated in Fig. 3 herewith. In all metal conduit systems the use of insulating bushes is necessary to protect the insulation of the wires and cables emerging from the free ends of the conduits.

Special attention is directed to the very substantial reduction in prices of all Simplex conduits and fittings, which is now rendered possible by the lowering of manufacturing costs, attained by the equipment of the company's works with the latest labour-saving machinery, coupled with their largely increased output.

For the rest, it remains to commend the convenient form of this list for the breast-pocket, its excellent binding and compilation.

Peck; "The Slow Stretch in Indiarubber, Glass, and Metal Wires when subjected to a Constant Pull," by Mr. J. Phillips; "Determination of Young's Modulus for Glass," by Mr. C. A. Bell; and "Some Methods for Studying the Viscosity of Solids," by Dr. Boris Weinberg.

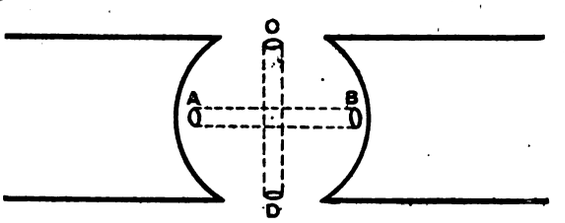
## DESCRIPTION OF SOME PLANT INSPECTED DURING A RECENT VISIT TO THE STATES.*

BY H. L. RISELEY.

In response to your committee's invitation to submit a paper to the local section on my general impressions during a recent trip over to the other side, it appears to me that so many papers are being read, and so much has already appeared in the technical Press as regards power stations, traction, and other kindred subjects, that it would be superfluous to present anything on similar lines. It occurred to me that it would be of more general interest if I were to give a description of such apparatus as appeared unique or different from our standard practice, and which came under my observation. By the great courtesy of the various manufacturers, I managed to gather a good deal of information as regards single-phase traction motors—a subject which I wish to deal with this evening.

*General Principles of the Single-Phase Railway Motor.*—Of course, it is well understood that if the current in both the field and armature of a direct-current series motor is reversed, the direction of rotation of the armature will remain unchanged. If the current was only reversed once an hour, or once a minute, we should not find any difference in the operation of the motor, and with more frequent reversals of the current the same principles should apply. With a direct current rapidly reversed an effect similar to that produced by an alternating current is obtained, and therefore it is only natural to expect that alternating current applied to a direct-current series motor should produce continuous rotation in its armature. However, there are certain phenomena peculiar to alternating currents which have made the operation of the single-phase motor a difficult problem. One of these is the loss which occurs in any solid iron core if the magnetism is rapidly changed in strength, or reversed in direction. This is greatly reduced if the iron core is made laminated. A more serious difficulty, due to the alternating magnetism, is the transformer action which occurs between armature and field.

Suppose C D be an armature coil in a two-pole machine at position of commutation. Owing to the passage of alternating magnetism from one pole to another, there will be a voltage induced in each of the armature coils by transformer action entirely independent of their speed of rotation. This voltage will be different in the different coils, depending on their position, and will be maximum in the coil C D, which is at right angles to the flux, and zero at A B. As each commutator bar passes under a



brush, an armature coil is momentarily short-circuited. The armature coils are thus short-circuited consecutively in the positions where the greatest E.M.F. due to transformer action is induced in them. The result is an excessive current in each coil at the moment it is commutated. Means to neutralise this effect is taken auxiliary field windings, arranged between the poles. Other things being constant, the value of the induced E.M.F. will be proportional to the frequency of the alternating current supplied, and therefore the alternating-current motor is most easily designed for low frequencies.

THE GENERAL ELECTRIC COMPANY'S COMPENSATED MOTOR EQUIPMENT.

This apparatus was in commercial use on the Ballston division of the Schenectady Railway, and the details of the equipment are as under: total length of line, 15·5 miles; inside city length of line, 3·9 miles; interurban portion of line, 11·6 miles; weight of rail (double T), 75lb.; maximum gradient, 1·8 per 100; maximum curvature, 4·25deg.; spacing between poles, 100ft.; size of trolley wire, alternating-current and direct-current, 000; alternating-current trolley suspended from ⅜in. steel catenary; voltage on trolley, 2,200 alternating current, 25 cycles; maximum speed, alternating-current and direct-current, 43 miles; wheel base of car, 6ft.; each motor 50 h.p., 200 volts alternating current, 300 volts direct current; motors connected permanently, two in series; trolleys per car (two alternating-current and two direct-current); average speed per hour (not including stops), 32 miles; volt-ampere hours per ton-mile, 4,350 direct current, 6,330 alternating current.

The purpose for which this apparatus has been designed is (as is well known) that with a direct-current voltage of 600 volts a suburban system is a commercial possibility, but when an extended and heavier service is needed the cost of copper required at 600 volts becomes a serious item, and the position from a commercial point of view assumes a different aspect; consequently there has been felt a need for a higher trolley voltage. The use of alternating current for the trolley would allow a higher voltage than is possible with direct current, as the voltage can be reduced on the car by a transformer to the potential required by the motors. The general practice of large power companies has been to generate at a high voltage and to transmit to sub-stations, and there to change the alternating current to direct current for use on railways by means of rotary converters or other similar commutating devices. Obviously it would be of great advantage if the railway motors could be operated from the high-voltage trolley, thus saving all the expensive intermediate transforming apparatus. The proposed scheme offers the double advantage that it can be operated on systems where direct current is already installed, and alternating current can be easily adopted for future extensions. The single-phase alternating-current motor offers several advantages over the three-phase motor, due to the limitations of the latter. The alternating-current single-phase commutator motor, with its inherent fitness for heavy traction work, has attracted the attention of engineers all over the world for some considerable time past.

*Motor.*—The motor has the general appearance of the usual direct-current traction motor. It has compensated field windings in order to neutralise the heavy reaction of the armature. Both the compensated motors and control are adapted for operation on the 2,000-volt alternating between cities and the standard 600-volt direct current inside the city line. The compensated motor is essentially a variable-speed motor, differing in this respect from the three-phase induction motor, whose constant speed features proved such a drawback to its successful adoption in railway work. The speed torque of the compensated motor is very similar to that of the direct-current series motor, while its commutating qualities and method of control are equally satisfactory. The alternating-current compensated motor consists of an annular laminated field with distributed windings similar to that of an induction motor, and an armature provided with a commutator similar in general construction to a direct-current railway motor armature. These motors are wound for 200 volts, and are connected permanently two in series, being fed from the 400 volts secondary of an 80-kw. air-

*Paper read before the Newcastle Local Section of the Institution of Electrical Engineers, Jan. 16.

Digitized by Google

blast transformer carried on the car. The distributed character of the field windings fully compensates for the armature reaction, so that the power factors are relatively high throughout the range of operation. A set of motor characteristics (Figs. 1, 2, 3, and 4) are shown in accompanying diagrams for both alternating-current and direct-current running. It will be noticed that the speed torque characteristics for alternating-current running are equal to direct-current in meeting the requirements of railway work. Unlike the three-phase induction motor, with its practically constant speed characteristic, the compensated alternating-current motor varies its speed with its load, and is better adapted to operate traffic over an irregular profile. The commutation is equally satisfactory whether running alternating current or direct current, and this good commutation has been obtained by careful design, without resort to high-resistance leads or other devices likely to give trouble in case of heavy and long-sustained overloads. The following

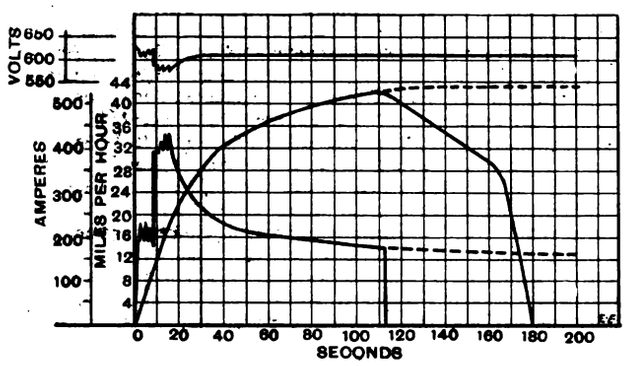


FIG. 1.—Speed Time Curve, D.C. Running. Four G E A 604 Compensated Railway Motors. Total weight of Car, 31·55 tons. Length of run, 1·6 miles. Gear ratio, 3·74. Diameter of wheels, 34in.

figures show the comparative alternating-current and direct-current resistance of trolley and track per mile :

| | D.C. resistance. | A.C. resistance. 25 cycles. | Ratio A.C./D.C. |
|---|---|---|---|
| Two trolleys in series ..... | ·318 ..... | ·417 ..... | 1·31 |
| One trolley and double track | ·167 ..... | ·259 ..... | 1·55 |
| Two trolleys and double track | ·088 ..... | ·155 ..... | 1·76 |
| Double track alone ..... | ·0174 ..... | ·114 ..... | 6·55 |

*Track and Line.*—The special features noticeable (as far as it was possible to observe) were that the alternating-current trolley wire was suspended from ⅜in. steel catenary, the wire being clipped to the catenary midway between poles, and the catenary in turn being hung over very heavy porcelain insulators on wooden cross-arms, the whole forming a construction of great flexibility, with the additional advantage of providing excellent insulation with standard porcelain insulators, and thus eliminating span wires

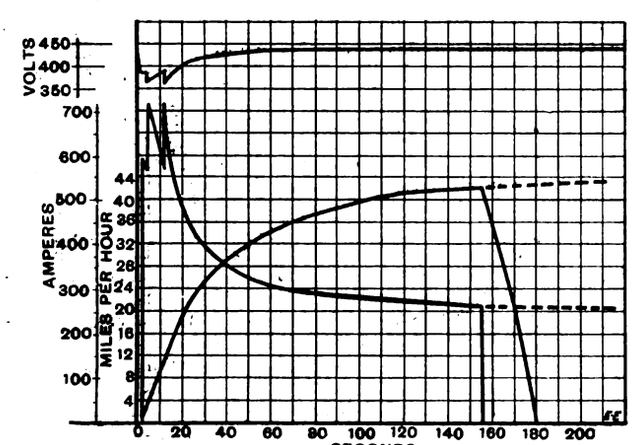

FIG. 2.—Speed Time Curve, A.C. Running. Four G E A 604 Compensated Railway Motors. Total weight of Car, 31·55 tons. Length of run, 1·6 miles. Gear ratio, 3·74. Diameter of wheels, 34in.

adjacent to the trolley wire, thereby preventing the pole catching in the event of the trolley jumping the wire. With alternating current using a track return there is an inductive drop in the wire and rails, with an additional loss in the latter due to eddy currents and hysteresis. Of course, the resistance of the alternating-current trolley wire is somewhat reduced by the steel catenary parallel with it. The track is cross bonded every 1,500ft.

*Sub-Station.*—The present sub-station operating the Ballston line is operated from the Hudson River Power Company's station, but owing to the fact that this company generates at 40 cycles, it became necessary to instal a frequency-changing device, an inverted converter being used, obtaining direct current straight from the direct-current 'bus bars of the sub-station. The sub-station feeds direct into trolley wire at 2,200 volts, with no outside transforming sub-stations. (The sub-station is shown in the attached diagram, both an intermediate and terminal sub-station feed from a single-phase source of power being indicated ; Figs. 6 and 7.) When it is desired to instal and make use of a three-phase generator to take care of the operation of rotary converters, induction motors, etc., the preferred arrangement to balance the load at each sub-station is to instal three-phase two-phase transformers connected two-phase on the secondary side, and feeding separate circuits from the two-phase. This is also shown in attached sketch. In the case of the Ballston line there was no difficulty in running the alternating equipments over the direct-current, this being accomplished by means of a standard direct-current series-parallel

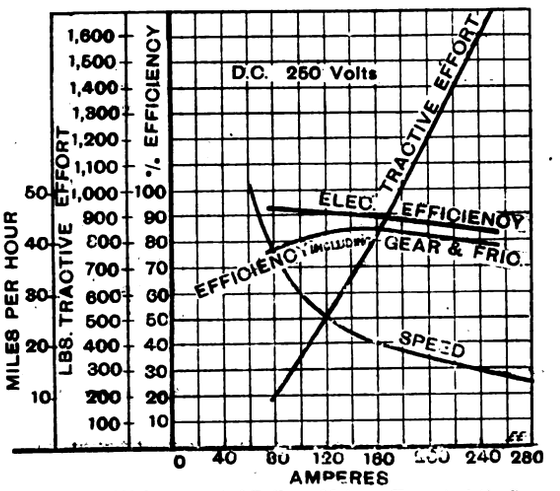

FIG. 3.—G E A 604 Compensated Railway Motor. Characteristic Curves. Gear ratio, 71 19=3·74. Diameter of wheels, 34in

controller used in connection with a commutating switch to change field connections, cut out step-down transformer, change line fuses, etc. The time required to operate the commutating switch is only a few seconds, and can be done while the car is travelling at full speed, as will be seen from the diagram (Fig. 5). The commutating switch is interlocked with two main oil switches, one being in the high-tension alternating current and the other in the direct-current, this interlocking being so arranged that only one switch can be closed at a time, and the commutating switch can only be thrown over when the oil switches are in the off position. Owing to the fact that the alternating-current trolley wire is off the centre while the direct-current is directly central, it has been necessary to provide a double set of poles, one for alternating current and the other for direct current, hence the necessity of interlocking the oil switches and commutating switch to prevent trouble in the case of both trolley poles being up at the same time.

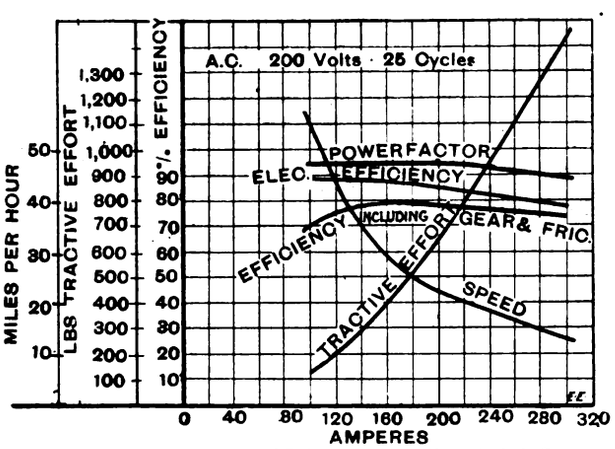

FIG. 4.—G E A 604 Compensated Railway Motor. Characteristic Curves. Gear ratio, 71/19=3·74. Diameter of wheels, 34in.

*Transformer.*—The 80-kw. transformer is air-cooled, forced draught being obtained by the motion of the car itself. The transformer is suspended below the car floor, and all primary leading-in wires are carried in brass tubes, which are well earthed. Car lighting and heating is effected from the direct-current trolley in the standard manner, and from the alternating-current trolley from the secondary of the transformer. The base of alternating-current trolley standard is treated with vacuum compound, and further insulated from the car body by composition insulators. The air-compressor for brakes and whistle is operated by a compensated motor, which operates from the alternating-current and direct-current trolley wires.

### WESTINGHOUSE SINGLE-PHASE RAILWAY MOTOR.

The Westinghouse motor does not differ materially in appearance from the G.E. motor, only the method of operating is

Digitized by Google

entirely different, for, whereas the G.E. use a resistance for regulating, the Westinghouse use an auto-transformer. Even in direct-current railway equipment the method by which speed regulation is obtained on series-wound motors is clumsy and inefficient. With series-parallel control it possesses but two

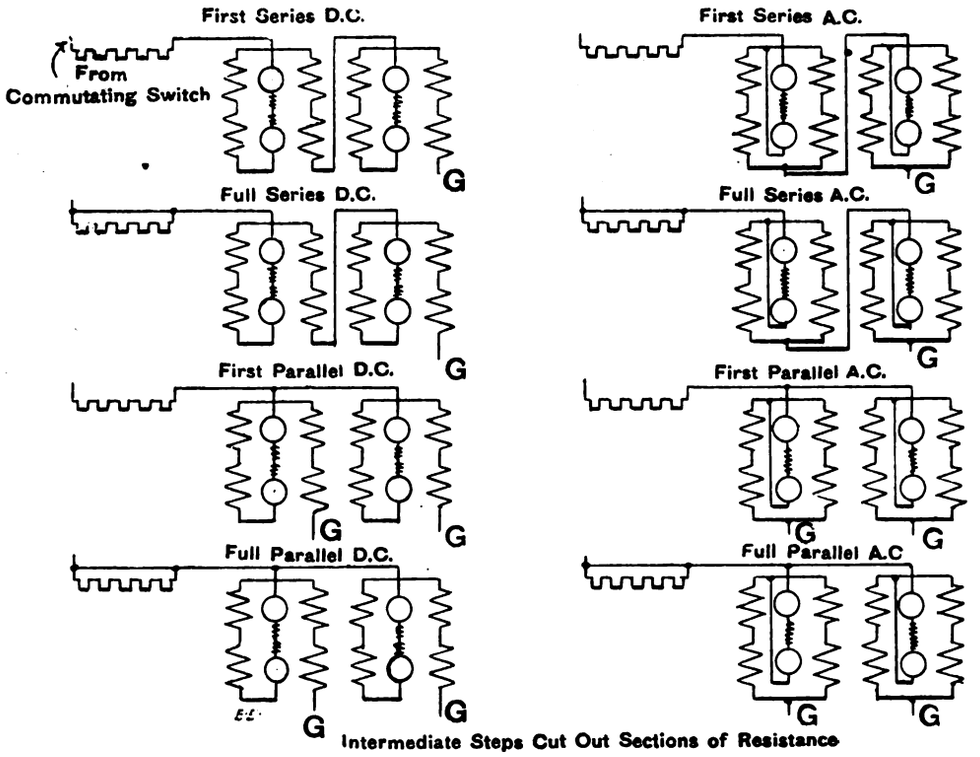

FIG. 5.

economical running speeds—*i.e.*, with motors in series and motors in parallel with no resistance in circuit. Any other speed of the car is only secured at an immense sacrifice of efficiency, involving a wasteful absorption of energy in the controlling resistance. At present there is no standard con-

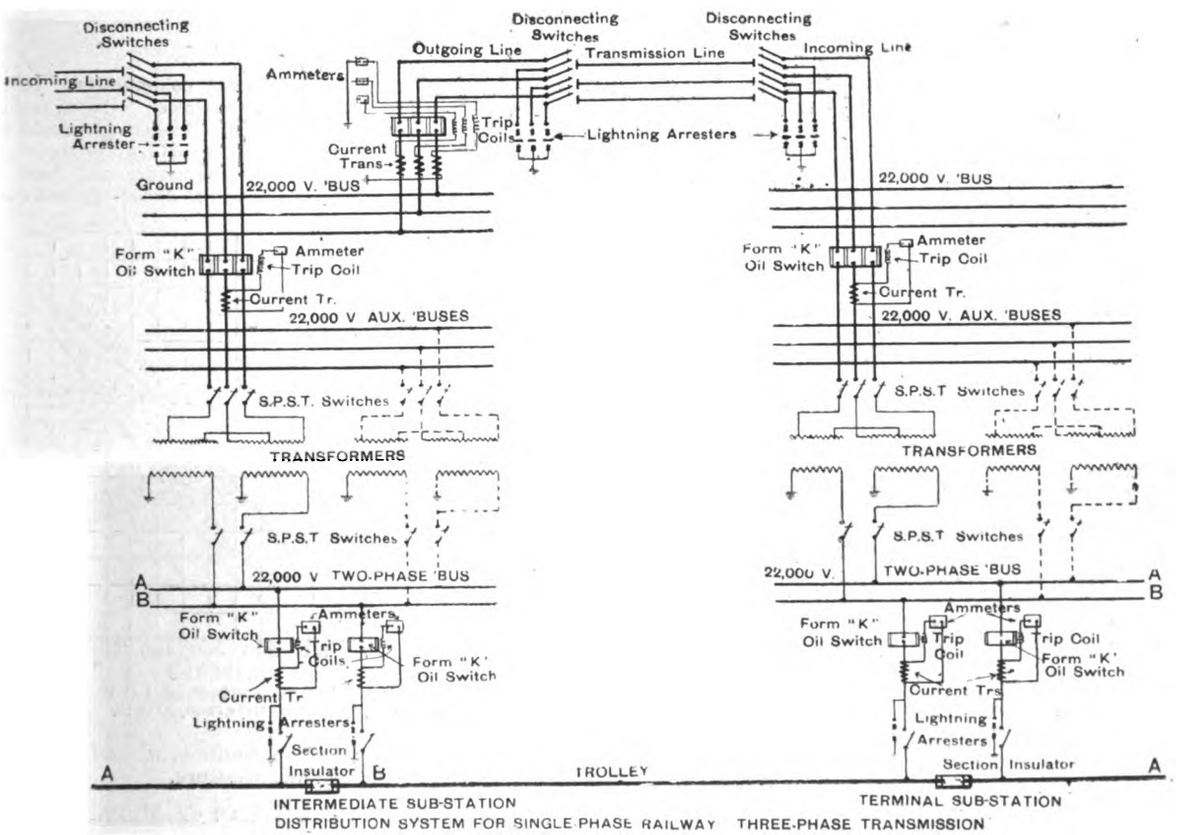

FIG. 6.

trolling device which will permit running on a resistance point any length of time, it being impossible to equip a car with sufficient resistance capacity for continuous operation. The Westinghouse alternating-current single-phase motor apparently overcomes all these difficulties. Its important points are described below.

*Field.*—A laminated core built up of circular punchings of soft steel bolted together is rigidly held within a cylindrical frame of cast steel. A large opening over the commutator and hand-holes in the end covers and bottom of frame provide easy access to the commutator and brushes, and permit inspection of the field and armature. The coils are wound with copper strip bent on edge and insulated. The field coils are connected permanently in series.

*Armature.*—A drum type core with open slots is wound with machine-formed coils of copper strip connected in multiple. The coils are held in place by a retaining wedge of hard fibre, which fits in grooves punched in the armature teeth. There are no band wires over the core. The motor is wound for 225 volts and a frequency of 25 cycles or less. At normal voltage and full load the speed is 700 revolutions per minute. Characteristic curves attached (Fig. 8).

Digitized by Google

*Main Transformer.*—An auto-transformer is provided to reduce the trolley potential to that desired at the motors. It is of the shell type, with single coil, and of standard construction.

*Lighting Transformer.*—The lighting transformer is also of standard type, and may be of any suitable size. Current for car heaters may also be taken from the secondary of this transformer.

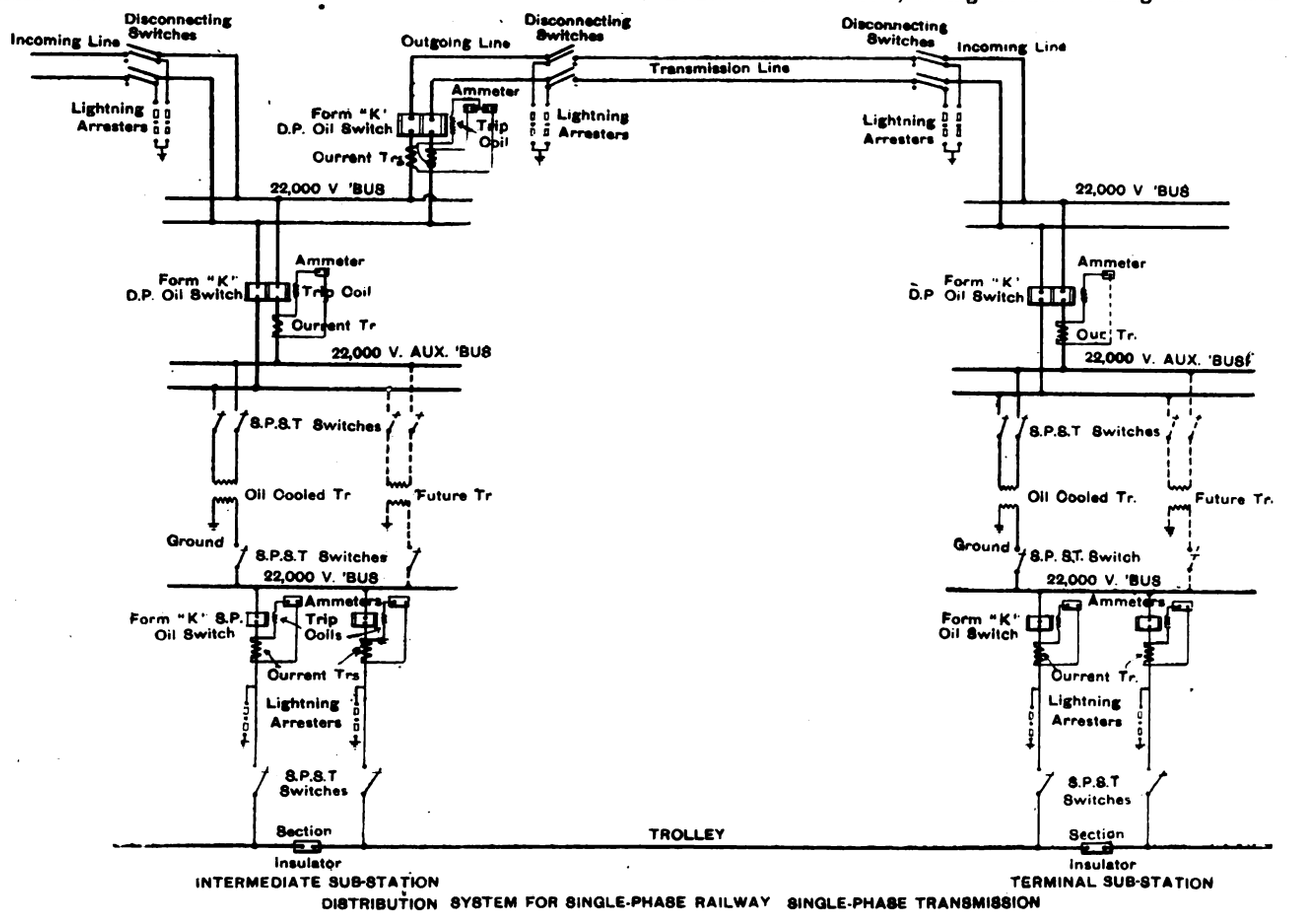

FIG. 7.

*Induction Regulator.*—Speed control is obtained by the induction regulator, without the interposition of any serious resistance. The regulator consists of two coils shown in diagram (Fig. 7) wound on two separate cores and so mounted that their relative angular position may be varied at will. The primary coil is connected between the trolley and the motors. One end of the secondary coil is connected to auto-transformer, A the other joins the primary at the motors. The voltage developed in the secondary coil varies with change of angular position, and may be either added to or subtracted from that of the auto-transformer. This method provides a voltage range of double that of the regulator, and consequently permits the use of a smaller size than would otherwise be possible. The regulator is operated by an air-motor connected to the shaft by a worm gear, and controlled by magnet valves.

*Switches.*—The main and reversing switches are of the drum type, operated by pneumatic cylinders, and controlled by magnet valves.

*Arrangement of Apparatus and Car Wiring.*—The induction regulator, main and reversing switches, and car circuit breaker are all operated by magnet valves, controlled from either of the master controllers. These magnet valves are actuated by a low-voltage current from a small battery. For the multiple control of a train, it is therefore only necessary to carry this low-voltage battery circuit from car to car. Seven-point plugs and sockets provide for making these connections. The four motors are arranged in pairs, each consisting of two armatures in series and two fields in series. The two pairs are connected in parallel. The equipment is designed for operation at a trolley potential from 1,000 to 1,200 volts, reduced by the auto-transformer on the car to 300 volts. The presence of the auto-transformer and induction regulator on the car offers a safeguard against damage to the motors by lightning or to other disturbances on the line. Motors of this type are operated on a direct-current line. This involves no change in the motors or line construction, but necessitates a modification of the controlling apparatus.

*General Remarks.*—The general resemblance of the alternating-current motor to the direct-current series motor, both in appearance and methods of operation, also in many details, is really surprising. The frame of the alternating-current railway motor, like that of the direct-current motor, is of cast steel, but the entire magnetic part of the field (poles and yoke) is laminated. This, of course, differs from the direct-current motor, where the poles alone are laminated, and the cast-steel frame also acts as the magnetic yoke. The poles of the alternating-current motor are shorter than those of the direct-current motor, and carry only a very few turns of heavy strip winding. The armature is in all essentials similar to that of the direct-current motor, having much the same general dimensions, and being fitted with the same commutator. Instead, however, of only two brush arms, the lower voltage, and consequently larger current motors of the alternating-current type, require one set of carbon brushes per pole in order to avoid excessive commutating current. The armature and field coils are connected in series precisely as in the direct-current motor,

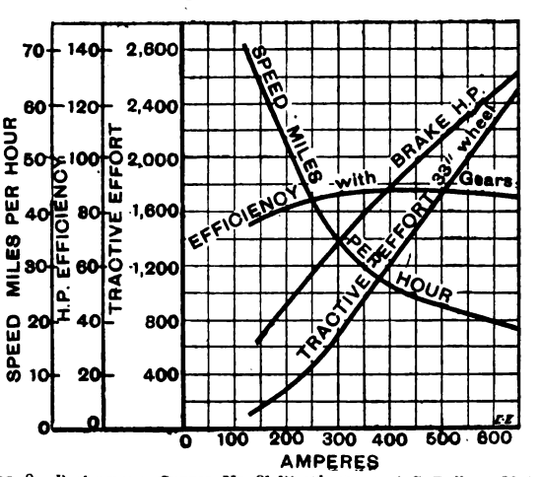

FIG. 8.—Performance Curves, No. 91 Westinghouse A.C. Railway Motor, 200 volts, 3,000 alts. Gear ratio, 20 to 62.

but there is an auxiliary field in addition, which is also placed in series with the main field and armature.

### WESTINGHOUSE UNIT SWITCH SYSTEM OF MULTIPLE CONTROL.

The above system consists of a controller operated by the motorman, with connecting leads to various air-switches on each motorcar. A unit switch-control equipment comprises: unit switch group, reverse switch, controllers, train line, diverters, limit and line relay switches, small storage battery, air connections. The storage battery is the independent source of current for the operation of air switches. Their control is secured by the movement of the controller, which completes

Digitized by Google

the circuits to the various magnets' valves on each motorcar, which in turn secure the operation of corresponding air switches. The various resistance and motor changes are thus simply and positively attained. The air supply is common to the brake system, and its use so slight as to be negligible. A separate air reservoir is installed, thus obtaining a continuance of air supply for control operation in case of the failure of the air-breaker. The contacts are of peculiar construction, and are closed with a rocking and wiping motion, which keeps the surfaces smooth and bright. The magnet valves which control the several unit switches are so interconnected by simple mechanical interlock switches that the closing of one switch energises the magnet of the adjacent switch. The automatic progressive action thus provided is regulated by a "limit switch," so

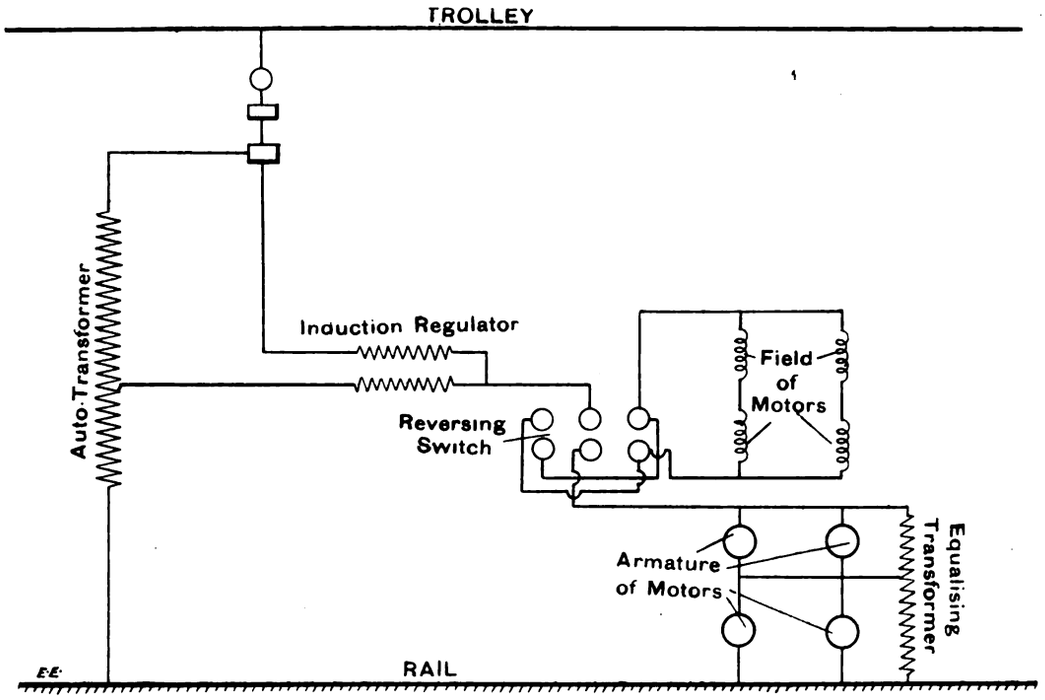

FIG. 9.

compressor. The certainty of positive contact, which is of such great importance in the continued handling of heavy currents, is obviously thus independent of a fluctuating line voltage. The expenditure of energy for the closing of switches, although small, continues only during their movement. The use of 14 volts for the control operating voltage secures the greatest

adjusted that the various switches are successively closed to afford uniform acceleration with a constant motor current. The rate of acceleration is determined by the adjustment of the limit switch, which consists of a small switch in the control circuit governing the progressive movement of the unit switches, and is actuated by an electromagnet in series

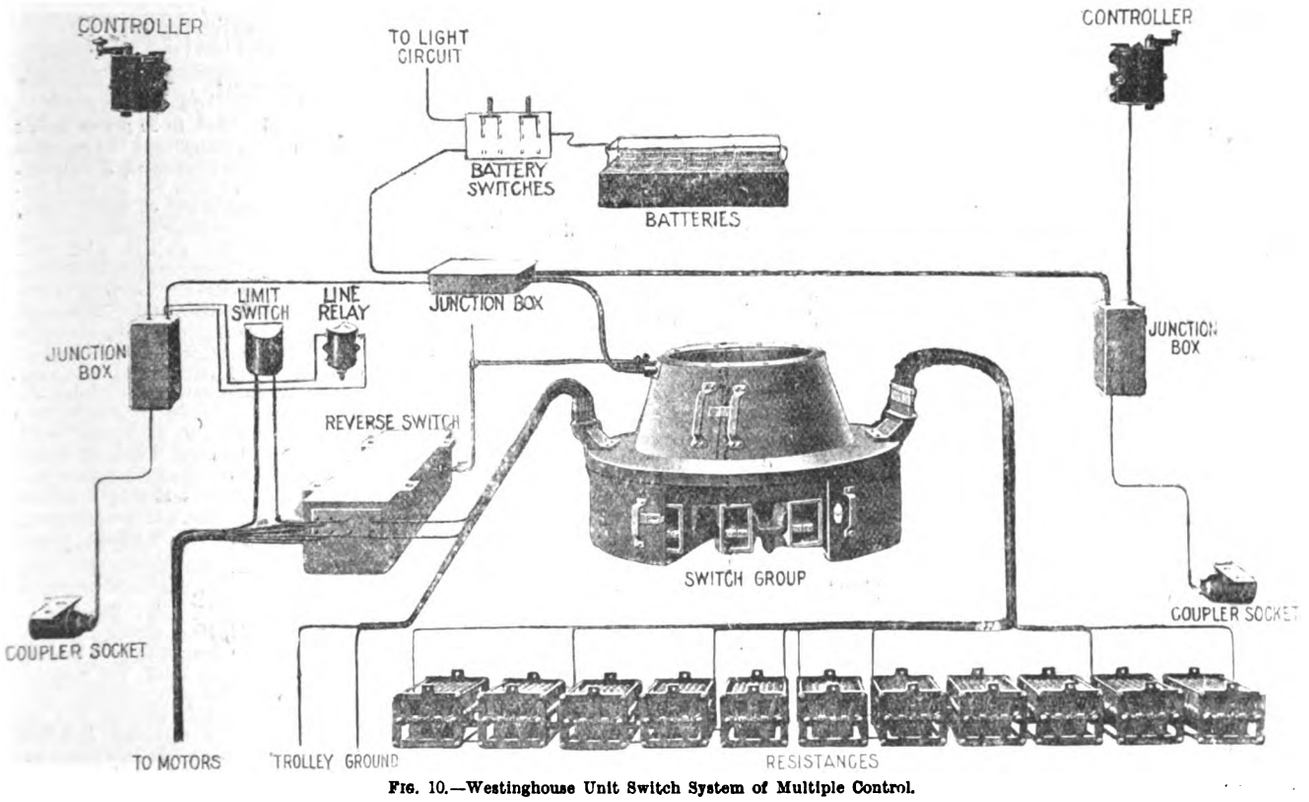

FIG. 10.—Westinghouse Unit Switch System of Multiple Control.

freedom from deteriorating contacts, short-circuits, and burn out of coils or wiring.

*Unit Switch Group.*—A number of independent switches are grouped together radially about a central air reservoir and operated by small pneumatic cylinders, the valves of which are controlled by electromagnets. This compact arrangement makes possible the use of a single magnetic blow-out coil for the entire group. Each switch, in fact, becomes a circuit

with the motor circuit, so that the switch is opened and the progressive action of the unit switches arrested whenever the motor current reaches a predetermined amount for which the limit switch has been adjusted. As soon as the motor current falls below this amount the switch closes, and the progressive action of the unit switches is continued. This arrangement ensures practically constant current per motor during the advance of the unit switches.

Digitized by Google

*Line Relay.*—This apparatus is used to cut off the current from the line should the supply fail at any time, and is actuated by an electromagnet connected across in shunt across the supply circuit, so that the relay circuit is held closed unless the current supply is interrupted.

*General.*—The Westinghouse Company claims the following advantages for the above system: Freedom from failure due to crossed circuits or burn-outs; absence of trouble with control circuit contacts; simplicity of circuits to secure automatic current input; light weight and small space; ease of installation; ease of inspection; certainty of efficient contact on unit and reversing switches; great strength of blow-out; regularity of current input; economy of operation; absence of welding of contacts; great protection from abuse and neglect.

# LEGAL INTELLIGENCE.

## WEYBRIDGE ELECTRIC SUPPLY COMPANY.

In the Chancery Division on Friday last, before Mr. Justice Joyce, an application was made by the Weybridge Urban Electric Supply Company, who have a station at Weybridge, to stay so much of an order obtained against them as applied to the lighting of Walton from the generating station at Weybridge. The matter has been the subject of considerable litigation recently.

**Mr. Younger,** for the company, stated that the injunction obtained against the company on Sept. 22 had been suspended, so that the company might approach the Attorney-General.

**His Lordship:** I object to your saying this.

**Mr. Younger:** I will put it in any form you like. Proceeding, he said his company did approach the Attorney-General, but he was content to leave the matter in his lordship's hands. They had presented a Bill to Parliament authorising them to supply Walton from their Weybridge station. That Bill was now pending. The proposal he made to his lordship in the interests of the company, and of the consumers at Walton, was that part of the injunction which only related to the actual supply by means of the existing mains—leaving out of account the breaking-up of the roads or anything of that sort—should be suspended until the Bill which was now pending in Parliament had been disposed of either one way or the other. The actual supply at Weybridge had been going on for 18 months, and the company had erected in Walton a temporary station, which was completed.

**Mr. Hughes,** on behalf of the Urban Council, said at present there was a decision against the company, but what they were doing was contrary to the law—it was a clear breach of the law—and what the company said was, "allow us to go on committing a breach of the law until the law is altered."

The Judge granted a stay of the injunction previously made until any further order may have been made.

Mr. Hughes asked leave to appeal, which the Judge, after considerable hesitation, allowed.

## SOUTH LANCASHIRE ELECTRIC TRAMWAYS.

At the Chancery Court, Liverpool, last week, before Vice-Chancellor Sir S. Hall, K.C., the affairs of the South Lancashire Traction Company came up again for consideration in the form of two motions—one by Mr. Nicholas Earle, solicitor, Manchester, seeking to restrain the company from acting on resolutions passed at a meeting held on Dec. 30; and the other by Mr. Arthur Stanley, asking the Court to give effect to the resolutions. Both applicants were debenture holders in the company.

Counsel for Mr. Earle stated that some time ago a summons came before the Court asking it to sanction the terms of a Bill in Parliament and the raising of a sum of money for expenses, and that application failed. Nevertheless, a meeting was summoned for the purpose of considering and, if thought fit, of supporting the Bill of the South Lancashire Tramways, Limited, to extend the time for the compulsory purchase of lands and the rearrangement of capital in that company, and for the purchase of the undertaking of the electric traction company. The meeting was wholly irregular, and his client purposely refrained from attending, and the resolutions passed at it ought not to have any effect.

Counsel for two other debenture holders explained that in order to comply with the Standing Orders of Parliament notice had to be given in the local papers and meetings had to be called, and it was necessary to hold the meeting in question in order to be in time to present the Bill next session. If the compulsory powers held by the company were allowed to lapse it would seriously diminish the value of the shares held by the electric traction company, with a consequent loss to the debenture holders, and an enormous majority of the latter were in favour of the Bill.

**Mr. Maberly,** on behalf of Mr. Stanley, said that in such a case as this the Court could refuse an application at one time and grant it at another, according to its views of the circumstances. In this case the circumstances had changed, and the matter submitted to his Honour was not *res judicata*. It was anticipated that if the Bill were passed, a substantial value would be given to the shares held by the electric company.

It was stated in further argument that the holders of £502,000 out of £597,000 debenture stock were in favour of the Bill.

**His Honour** granted Mr. Stanley's motion, the costs to be paid by the trustees.

## MUTILATED TRAMCAR TICKETS.

At Sunderland on Friday last Andrew Bell was charged with wilfully obstructing a tramways inspector, and with refusing to produce his ticket when asked to do so.

**Mr. F. M. Bowey,** town clerk, stated that defendant and two other men boarded a car going from High-street to Grangetown. Defendant paid the three fares, and received three tickets properly punched from the conductor. A few minutes later Inspector Gray boarded the car to examine the tickets. When he asked defendant for his ticket, he produced three tickets all in pieces and massed together. The inspector could not ascertain the number, or whether the tickets were all there, the only thing he could see being that one ticket was complete though in pieces. He told defendant that he could not find the numbers of the other two tickets, and the defendant replied that it was the inspector's duty to look for the numbers and not his. He further stated that he had torn the tickets up intentionally in order to have a test case made of it. He gave his name and address when requested to do so. As soon as the inspector went upstairs the conductor of the car saw Bell stoop down and pick several pieces of tickets from the floor.

Corroborative evidence was given by the inspector and the conductor.

**Defendant** said the tickets were mutilated, but not destroyed, and the pieces—perhaps eight in all—were all together. The by-law stated that tickets must not be destroyed, and his were not destroyed.

**Mr. Bowey:** We are not charging him with destroying his ticket, but with obstruction.

**Harry Gordon,** a clerk, gave evidence in support of the defendant, and said the tickets were probably in 12 pieces. If the inspector had looked properly he could have found the other numbers. The tickets were mutilated, but not destroyed.

**Robert Wm. Haggie** also gave evidence, and said the tickets would be torn into 24 pieces, or probably less. The inspector could have found the numbers if he had liked.

The Bench said they found the case proved, and inflicted a fine of 20s., including costs.

## TRESPASS ON THE LANCS. AND YORKS RAILWAY.

A case of trespass on the electrified section of the Lancashire and Yorkshire Railway was heard before the Southport magistrates, the defendants being two men named Jones and Eannon.

A pointsman saw the defendants near the "live" rail. Eannon challenged Jones "to go and sit on the 'live' rail," but Jones did not accept. Both defendants were under the influence of drink, and the pointsman telephoned for assistance. Three porters were then sent up the line, and when they requested defendants to get away, Eannon again requested them to show him the "live" rail, stating that he was "prepared to meet his Maker." The defendants several times lurched into dangerous proximity to the "live" rail, but were eventually removed from the rails without mishap.

Both men were fined 20s. and costs.

# COMPANIES' MEETINGS AND REPORTS.

## EASTERN TELEGRAPH.

The report for the half-year ended Sept. 30, 1904, to be presented at an ordinary general meeting on the 25th inst., states that the revenue amounted to £589,386. 6s. 2d., from which are deducted £178,269. 13s. 7d. for the ordinary expenses and £41,847. 17s. 7d. for expenditure relating to maintenance of cables, depreciation of spare cable, sundry differences in exchange, and income tax payable abroad, leaving a balance of £369,268. 15s., to which is added £1,233. 13s. 10d. brought from the preceding half-year, making a total available balance of £370,502. 8s. 10d. After providing for income tax payable in England, interest on loan from Eastern and South African Telegraph Company, Limited, interest on mortgage debenture stock, and for two quarterly dividends on the preference stock, which in all absorb £97,870. 9s. 11d., there remains a balance of £272,631. 18s. 11d., out of which the directors have placed £12,000 to the reserve fund for maintenance ships, £125,000 to the general reserve fund, and allocated £100,000 to meet the two interim dividends of 1½ per cent. each on the ordinary stock, the balance of £35,631. 18s. 11d. being carried forward to the next account. Two of the directors, Lord Allerton and Sir Henry Charles Fischer, C.M.G., retire by rotation, but offer themselves for re-election, as also do the auditors, Messrs. Deloitte, Dever, Griffiths, and Co., and Messrs. Welton, Jones, and Co.

## DIRECT UNITED STATES CABLE.

The report for the half-year ended Dec. 31, 1904, states that the revenue, after deducting out-payments, amounted to £51,030, as compared with £47,815 for the corresponding period of 1903. The working and other expenses for the same period, including income tax, amounted to £22,108, leaving a balance of £28,921 as the net profit, making, with £2,168 brought forward, a total of £31,089. For the corresponding period of 1903 the working expenses and other payments amounted to £21,816. Interim dividends of 3s. per share for the quarter ended Sept. 30, 1904, and of 3s. per share for the quarter ended Dec. 31, 1904, amounting to £18,213, have been declared, and after setting aside £10,000 to the reserve fund account, the balance of £2,876 has been carried forward. The reserve fund account has been debited with £8,477 for cost of cable repairs, and after being credited with interest on the investments and amount set aside from revenue, now amounts to £472,964, taking the investments at cost price. The directors recommend a pension scheme for the staff of the company, to take the place of the existing system of endowment assurances.

## NEW COMPANIES REGISTERED.

**General Electric de France, Limited.**—Capital, £10 000. Object: to acquire and carry on the business of Messrs. L. Espir and N. Gunz as dealers in electrical apparatus and appliances at 11bis, Rue de Maubeuge, Paris. Registered office: 67, Queen Victoria-street, E.C.

### Liens Registered.

**Minehead Electric Supply Company, Limited.**—Discharge registered Jan. 2 of debenture and mortgage as collateral security, dated April 24, 1903, for £700.

**Sir Henry S. Maxim Captive Flying Machine Company, Limited, Westminster.**—Lien registered Dec. 29 for £4,000 7 per cent. debentures, and, as collateral security, an assignment by way of mortgage for securing a like sum. Holder: Sir H. S. Maxim; the debentures being secured on all the property, present and future, the undertaking, goodwill, business, and uncalled capital for the time being, and the assignment on all moneys payable under agreements with the London Exhibitions, Limited, and the Crystal Palace Company.

## APPOINTMENTS VACANT.

**Switchboard Attendant**, Devonport electricity works. Wages, 30s. per week. Applications to the Borough Electrical Engineer. See advertisement in last issue.

**Manager**, London Motor Omnibus Company, Limited. Applications to the Secretary, 794, Salisbury House, London, E.C.

**Switchboard Attendant**, Stockton-on-Tees. Wages, 27s. 6d. per week advancing to 35s. per week. Applications to Mr. J. J. Smith, borough electrical engineer. See advertisement.

**Electrical Engineer**, Ashton-under-Lyne Union. Particulars from Mr. G. H. Parrington, clerk to the Guardians. See advertisement.

**Chief Assistant Electrical Engineer**, Battersea. Salary, £175 per annum.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Keighley.**—The Corporation invite tenders for tramcars. Tenders by Jan. 30.

**Halifax.**—The Corporation invite tenders for coal conveyors. Tenders by Jan. 31.

**Tourney.**—Tenders are required for the electric lighting of the waterworks. Tenders by Jan. 20.

**Saragossa (Spain).**—Tenders are invited for 32 candelabra for the municipal theatre. Tenders by Jan. 30.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**West Hartlepool.**—The Corporation require tenders for additional 250-kw. set, with the necessary switchboard, panel, etc.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Bucharest.**—The Government require tenders for the annual supplies to the Regie for lighting materials and accessories. Tenders by Feb. 7.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply of 10 complete feeder pillar boxes, with bases. Tenders by Feb. 1. See advertisement.

**Kirkcaldy.**—The Town Council invite tenders for the extension of about 500ft. in length of the present East Pier. Tenders to the Town Clerk by Feb. 4. See advertisement.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Vienna.**—Tenders are required for telegraph and telephone materials. Particulars may be obtained from the K. K. Post Oeconomie-Verwaltung, Vienna. Tenders by Jan. 31.

**Grimsby.**—The Corporation invite tenders for (No. 30) motors; (31) water-purifying plant; and (32) 12 months' supply of stores. Tenders for 30 and 31 by Jan. 23, those for 32 by Feb. 1.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Stockport.**—The Tramways Committee invite tenders for the overhead equipment of about four miles of electric tramway, and also for copper rail bonds. Tenders by Feb. 6. See advertisement.

**Caen (France).**—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1.

**Brussels.**—Tenders are required for erection of an electric station at the goods railway station at the port. Specification No. 391 is obtainable from the Belgian Government Railways. Tenders by Feb. 8.

**West Ham.**—The Council invite tenders for the supply of engine-room stores, cables, integrating wattmeters, double-pole house cut-out boxes, transformers, incandescent lamps, and coal. Tenders by Feb. 6. See advertisement.

**Pudsey.**—The Corporation invite tenders for underground electric mains, switchboard, etc. Specifications, etc., may be obtained on application to Messrs. Shepherd and Watney, consulting engineers, Greek-street-chambers, Leeds. Tenders to the Town Clerk by Jan. 20.

**Swindon.**—The Corporation invite tenders for the supply and erection of one 30ft. by 8ft. Lancashire boiler with down-take superheater, steam, exhaust, and feed piping, etc. Tenders to be delivered before 10 a.m. on Tuesday, Jan. 24, 1905, to Mr. Robt. Hilton, town clerk.

**London, N.**—The Metropolitan Asylums Board invite tenders for installation of fire-alarms at Northern Hospital, Winchmore Hill, N., in accordance with plan and specification prepared by Mr. W. T. Hatch, M.I.C.E., M.I.M.E., engineer-in-chief. Tenders by 10 a.m. on Jan. 24.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Drax (near Selby).**—Tenders are invited for electric light installation, also electric pump, etc., capable of delivering 500 gallons per hour, at Read's Grammar School. Apply to the headmaster, Mr. W. St. G. Drennan, at the School, who will supply all necessary particulars. Tenders to be delivered to Messrs. E. and T. Clark, solicitors, Snaith, R.S.O., clerk to the Governors, by noon on 28th inst.

**Johannesburg.**—The Council invite tenders for Vignoles rails, fishplates, angle steel guard-rails, bolts, nuts, coach screws, and dog-spikes. General conditions, specifications, and forms of tender may be seen at the offices of the Council's consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, Westminster, S.W., and may be obtained on payment of five guineas. Tenders by Jan. 26.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**Placencia.**—Tenders are required for the concession for 10 years of the lighting by electricity of the town. Adjudication of tenders will take place on Jan. 28, and tenderers, if not appearing in person, must be represented by a duly authorised agent. The conditions of concession are set out in the notice in the *Gaceta*, which may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C., any day between the hours of 10 a.m. and 5 p.m. (Saturdays, 10 a.m. to 1 p.m.).

**Tredegar (Mon.).**—The Guardians of Bedwellty Union invite tenders for a complete electric light installation at their workhouse, Tredegar: (Section 1) steam dynamos, booster, battery, switchboard, and motors; (section 2) cables and wiring. The plans, specifications, and forms of tender will be issued shortly. Firms desiring to submit tenders are requested to apply in writing on or before 25th inst. to the consulting engineers to Guardians, Messrs. Herbert Lewis and Fletcher, Prudential-buildings, Cardiff. Mr. J. A. Shepard, clerk, Town Hall, Tredegar.

**Handsworth (near Birmingham).**—The Urban District Council invite tenders for the supply and delivery of the following in connection with the electric lighting undertaking: (Contract No. 10) power and lighting circuits and fittings in generating station; (11) pipework, feed pumps, economiser, etc.; (12) electricity meters. Tenders will only be considered for the whole of the work covered by each specification, and not for any part thereof. Copies of the specification, with the conditions of contract, etc., can be obtained from Mr. H. Ward, clerk. Tenders to the Clerk before noon on Feb. 2.

**Melbourne.**—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess,

Digitized by Google

M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

### RESULTS OF TENDERS.

**Norwich.**—The Town Council have accepted the tender of C. A. Parsons and Co., of Newcastle, at £6,400, for a 1,000-kw. steam turbine generator.

**Fulham.**—The Borough Council have accepted the tender of the General Electric Company, Queen Victoria-street, E.C., at £6,718, for the 1,000-kw. alternator.

**Leith.**—The Council at their meeting on Monday, after considerable debate, decided to place half of the order for the tramcars and equipment with the British Thomson-Houston Company and half with the Brush Company.

**Stockport.**—The Corporation Tramways Committee have accepted the tender of Walter Scott and Co., Leeds Steelworks, for rails, fishplates, and tiebars at nearly £7,000, for the reconstruction of the Hazel Grove and Edgeley tramway routes.

**Perth.**—The following tenders have been accepted by the Electricity Committee in connection with the reconstruction of the tramway system: for the engine and dynamo, the British Electric Plant Company, Alloa, at about £3,000; Cowan and Co., Salford, Manchester, for the switchboard, at about £1,100.

**Hull.**—The Public Libraries Committee have received the following tenders for the necessary electric light installation and fittings required at the Carnegie Library, West Park, Anlaby-road:

| | | | |
|---|---|---|---|
| W. L. Harrison, George-street, Hull (accepted) | £38 | 15 | 0 |
| Lancashire Electrical Engineering Company, Ashton-under-Lyne | 43 | 0 | 0 |
| Northern Electric Company, Grimsby | 49 | 0 | 0 |
| King and Co., South Church Side, Hull | 54 | 0 | 0 |
| H. Hyde, Spring Bank, Hull | 65 | 0 | 0 |
| Cox Walker, Darlington | 108 | 11 | 8 |

Note.—The price for fittings was not accepted.

## BUSINESS NOTES.

### TRACTION.

**Rothesay.**—It is reported that the extension of the tramway to Ettrick Bay is to be proceeded with immediately.

**Croydon.**—A confirmatory resolution in reference to the tramway extensions was adopted at last week's meeting of the Corporation.

**Colchester.**—At the special meeting called for the 11th inst. the Corporation approved the extension described in our last week's issue.

**Portsmouth.**—The Gosport Urban District Council have given their approval to the Portsmouth Street Tramways Company's Bill for additional lines.

**Newcastle.**—The city engineer has been instructed to prepare plans for the extensions to Sandyford Estate and Scotswood. Two top-covered cars are to be tried.

**Dalkeith.**—A syndicate project the construction of an electric tramway from Dalkeith to Lasswade, a distance of seven miles, if the local authorities are favourably disposed.

**Tranent (Scotland).**—At a public meeting it was unanimously decided to approve the proposal of the National Electric Construction Company to bring their Levenhall trams on to Tranent.

**Stockport.**—A meeting of the Tramways Committee was held to consider the tenders for the reconstruction of the Hazel Grove and Edgeley routes. Particulars appear in another column.

**Rawmarsh.**—The Urban District Council have agreed that if the promoters start construction by March 31, a reduction shall be made in the rent and consent will be given to an extension of time for completing the works.

**London County Council.**—The City Corporation have received resolutions from the Farringdon Within and Bread-street wardmotes in favour of bringing the cars over Blackfriars Bridge, and one from the wardmote of Walbrook against the proposal.

**Douglas.**—The Town Council considered on Wednesday a proposition to introduce 1d. fares all the year round in lieu of the 2d. fares now charged in the summer season. Ultimately it was decided to instruct the Tramways Committee to report on the advisability of introducing 1d. stages.

**Rhondda.**—A public meeting in connection with the omnibus Bill (including tramways) to be promoted in Parliament during the next session by the Urban District Council was held last week. After considerable discussion, in which a good deal of opposition was offered, the meeting was adjourned for a fortnight.

**Southampton.**—The proposal to appoint a general manager of the tramways has been referred to a joint conference of the Tramways and Electricity Committees, the opinion being expressed that if Mr. Street, the borough electrical engineer, were given an opportunity, he would discharge the additional duties of manager admirably.

**Coatbridge.**—At the monthly meeting of the Town Council a conversation took place with the British Electric Traction Company, as represented by Mr. Garcke, who stated that he would recommend the company to proceed with the construction of the tramway from Kirkwood-street to Woodside-street at an early date, though an extension of time for its completion will be necessary.

**Liverpool.**—The returns for the year ending Dec. 31 are as follows: car miles, 12,166,419; passengers carried, 116,642,663; receipts, £540,916; increase in traffic receipts, £16,407. The increase of receipts of 1903 over 1902 was £17,883, whilst 1902 over 1901 was £38,243. The biggest increase since the commencement of the electric system in one year was that of £57,645 in 1900 over 1899.

**Grimsby Light Railway.**—A special meeting of the Town Council was held on Monday to consider the plans of the proposed light railway which the Great Central Railway propose to lay down in connection with their Immingham Dock scheme. The application for sanction will come before the Light Railway Commissioners on Feb. 6. After considerable discussion it was decided to refer the matter to the Parliamentary Committee, which will meet at an early date.

**Electric Traction in Germany.**—According to the *Vossische Zeitung* numerous schemes are in contemplation for the construction of electric railways in Germany. These include lines Berlin Hamburg, Frankfort-Wiesbaden, Cologne-Dusseldorf, and Leipsic-Halle. Schemes for even longer distances are talked of, and it is claimed by the *Vossische Zeitung* that Germany will show herself to be the pioneer in electric railway construction apart from underground lines.—*Daily Telegraph.*

**Rochdale.**—A meeting of the Tramways Committee was held on Monday evening, when the chief item of interest was the question of Heywood running on the Corporation's lines with their steam trams from the borough boundary to Sudden. Heywood have struck out of the draft agreement certain clauses, the chief being that Heywood shall pay all rates and charges on the lines during the time they work them, and that they shall not at any time apply for running powers over this portion. It was decided by the committee not to agree to any of the alterations.

**Motor Tramcars.**—The *Morning Post* suggests that petrol motor tramcars should be run on existing tramlines where there are difficulties in the way of electrification. In view of the cost of electrification and the consequent opening of the streets, the London County Council is to be asked by the Shoreditch Borough Council to consider the possibility of adopting a system of automobile tramcars driven by petrol engines on the present lines north of the Thames, and to arrange with the North Metropolitan Tramway Company for the trial of an experimental motor tramcar.

**Leith.**—A requisition having been presented by four members of the Town Council to call a meeting to consider the action of the Tramways Committee in accepting an offer by the Brush Electrical Company for the supply of cars for the new electric system of tramways at £19,228, when a lower offer had been tendered, a special meeting was held on Monday. After various motions had been proposed and rejected, it was agreed to divide the order between the Brush Company and the British Thomson-Houston Company. Particulars will be found among our "Results of Tenders."

**New Tube Railways.**—The time for depositing in the Private Bill Office memorials alleging non-compliance with the Standing Orders of Parliament has expired. Memorials have been presented by the Marquis of Salisbury and Sir Walter Phillimore against the Great Northern, Piccadilly, and Brompton Railway (No. 2) Bill; and by Messrs. Pilkington Bros., Limited, Mr. Sydney Charles Lambert Messrs. George Wright and Co., Limited, and the Great Northern Piccadilly, and Brompton Railway Company against the Hammersmith City, and North-East London Railway Bill.

**North-Eastern Railway.**—At a meeting of the committee of the guarantors of the North-Eastern Passengers' Association held in Newcastle on Monday it was intimated that Sir George Gibb had written stating that the directors would be pleased to receive a deputation on 27th inst., and suggesting that the association should join with the corporate authorities and make one deputation. After some discussion it was resolved to adopt the suggestion, and several gentlemen were appointed to represent the different districts. Trials have been made of a new electric locomotive for goods traffic, and the results have been fairly satisfactory.

**North Metropolitan Tramways Co.**—Since the court of arbitration heard the evidence arising out of the claim for £105,000 by the North Metropolitan Tramways Company against the West Ham Corporation for the compulsory acquirement of the Swan-yard and Martin-street depôts, an arrangement has been come to between the parties on the following basis: no award to be made by the arbitrator, the Corporation to pay the tramways company £63,000 for the two depôts, the company to release the Corporation from all liability under the agreement dated Feb. 10, 1903, with regard to the Bow granaries, and immediate possession to be given of Swan-yard.

**Keighley.**—At the monthly meeting of the Town Council a councillor asked whether the Tramways and Electricity Committee intended to take the Council into their confidence and inform them as to how many passengers travelled on the cars month by month. In reply, it was stated that the information desired would be supplied regularly. Two new cars are being obtained, the manager having reported that it was practically impossible to work the whole system without them. All the existing cars are being used for the present service, and the two additional cars will be reserved for the new section, which will be opened in about a month. It is probable that the car-shed will have to be enlarged in the near future.

**Yarmouth.**—Negotiations with the Gorleston Tramway Company having failed, the Corporation have decided to apply to the Board of Trade for the appointment of an arbitrator. The December return shows an increase in receipts of £55 compared with last year. The aggregate report from April 1 shows an increase in receipts of £690. There have been 172 831 more passengers. The daily average receipts have increased by £2. 14s. 4d. The electrical engineer reported, after investigation, that the explanation of the excessive current consumed from the mains during the past five months by the trams was owing to the main meter reading off 10 per cent. too fast. The tramway accounts will be corrected accordingly.

Digitized by Google

**Timber Market.**—In their annual timber report Messrs. Denny, Mott, and Dickson, Limited, remark that, despite high prices and depression in the shipbuilding trade, a leading feature has been that the consumption exceeded the exports, the result being that the stocks of teak in consumers' hands have become exhausted, and shippers have consequently made their increased scale of prices effective. The result of this is to encourage the substitution of other woods or of steel for teak in rolling-stock construction. The imports of teak to Europe last year were 30 per cent. lower than the unusually small import of 1903, and as the consumption was some 20 per cent. in excess of the import, the stocks available are limited.

**Johannesburg.**—The Corporation are proceeding actively with the realisation of their tramway scheme, and Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W., the consulting engineers, are now inviting tenders for the permanent-way material, as also for rolling-stock, machine tools, etc. Those for the permanent-way material, deliverable by the 26th inst., include Vignoles rails, fishplates, angle-steel guard rails, bolts, nuts, coach screws, and dog spikes. The tenders for rolling-stock and machine tools, to be forwarded not later than March 8, comprise 100 electric cars and two electric water-cars, likewise a five-ton travelling crane, one electric car traverser, and various workshop tools—erection at Johannesburg being included in the contracts.—*British and South African Export Gazette.*

**Walsall.**—The following are particulars respecting the working of the tramways: Five weeks ending Dec. 3, 1904: Number of passengers, 400,754; receipts, £2,215. 4s. 6d.; car miles run, 57,558; receipts per car mile run, 9·23d. Four weeks ending Dec. 21, 1904: Number of passengers, 341,861; receipts, £1,900. 12s. 1½d.; car miles run, 44,707; receipts per car mile run, 10·20d. The town clerk has been instructed to confer with the borough accountant and manager as to the audit of the accounts, so as to facilitate the preparation of the balance-sheet. The electrical adviser to the Board of Trade has inspected the electrical equipment of the old lines, and has reported that the work is satisfactory. The Board of Trade have instructed Lieutenant-Colonel Yorke to inspect the permanent way.

**Leeds.**—Several important matters in connection with the fares were considered by the Tramways Committee on Monday. In the first place, it was resolved to recommend that all the 1d. stages throughout the city should be two miles in length. With regard to ½d. fares it was decided that an experiment should be made on about two-thirds of a mile of track on a route to be selected. Upon the result of this test will depend whether the system of ½d. fares shall be carried out all over the city. It was agreed to rearrange the working hours of the men engaged in cleaning and repairing the cars. At present they are on duty each night for eight hours, and under the new conditions they will work nine hours each night six times a week. In connection with the scheme of high-tension generation to supply current for the outlying districts of Horsforth, Rodley, etc., it was decided to advertise for tenders.

**London United Tramways Co.**—It was reported at last week's meeting of the Thames Ditton District Council that the construction of tramways in Long Ditton was about to be commenced. The Surbiton Urban District Council have referred back to committee the question of street widenings. It is stated that the line through Surbiton is not likely to be commenced before May. The Hampton Wick Urban District Council have passed the following resolution: "That an expression of opinion be sent from this Council to the Board of Trade to the effect that the construction of tramway lines over Kingston Bridge is at present impossible owing to the amount of traffic and the narrowness of the carriageway; and that the formation of the lines should be deferred until the bridge is widened." The Richmond Town Council have decided to oppose the company's application for an extension of time to construct the line from Kew Green to Richmond.

**Metropolitan Railway.**—The memorial which has been presented to the Examiner of Private Bills in both Houses by the Willesden Urban District Council against the Metropolitan Railway Bill is directed against Clause 35 of that Bill. This clause provides that "the company may enter into and carry into effect agreements with any railway or other company for the supply of electricity for traction, lighting, or other purposes." The District Council contends that this clause proposes to repeal, without proper notice, the proviso to Clause 31 of the Metropolitan Railway Act, 1902, which provides that the company shall not use or supply for use in the parish of Willesden electricity or electrical power except for the purpose of its own undertaking. Any proposed alteration or repeal of this proviso ought, it is contended, to have been served upon the Council, and the failure of the company to do so is, it is alleged, a non-compliance with Standing Orders.

**Heywood.**—At last week's meeting of the Corporation an agreement with the Corporation of Rochdale with respect to the running of the steam-cars to Sudden within the Rochdale boundary was approved. The Chairman of the Tramways Committee stated that he had met a deputation from the Rochdale Committee, and he thought they had beaten the matter out until there would be no difficulty in settlement. It was not convenient for Rochdale to work the tramways in Bolton-road, and as the Heywood Corporation had applied for permission to work them, it would seem that there could be no difficulty in arranging the matter; but Heywood were required to put the road in repair, keep the track in repair to the satisfaction of the Rochdale borough engineer, and be responsible for any damage that might be incurred. With a little alteration in the agreement he thought they would be able to come to terms with Rochdale. More communications have passed between the two towns, and the prospect of a settlement appears to be somewhat more hopeful.

**Jarrow.**—At the monthly meeting of the Town Council a communication was received from the Board of Trade enclosing copy of a letter from the solicitors to the promoters of the Jarrow and District Light Railway Order, 1901, regarding the proposed extension of time for completing the work. It was stated that the company had already spent more than £10 000 on the scheme, and in addition to purchasing property had completed both abutments of the proposed bridge over the River Don, having obtained delivery on the spot of the girders, and had practically completed the railway on either side of the bridge. But for the appearance of a crack in one of the abutments the construction of the bridge would before this have been actually completed. The company, therefore, thought they had shown sufficient ground to justify their requests for an extension of time for the completion of the railway and works, as they were not likely to allow the capital embarked in the scheme to lie idle longer than was necessary. In the circumstances the Board of Trade had sanctioned an extension for 12 months. Replying to a question, the Mayor said he did not think the Council could do anything further at present in the way of inducing the company to proceed with the laying of the lines.

**Mansfield.**—It is reported that a start is now to be made with the carrying out of the Mansfield and District Light Railways. During the week there has been a great deal of activity. The contract has been placed in the hands of Messrs. J. G. White and Co. The syndicate has abandoned the proposed site for car-sheds in Dallas-street, off Stockwell-gate, but terms for a lease of another site have been agreed upon. It is probable that work will be commenced at the extreme limits of the lines in the borough, leaving the laying of lines in the market place until the longer days in order to minimise interference with business. With regard to the completion of the work, the contractors are hopeful that May, when the extension of the order will expire under ordinary circumstances, will see the work in the borough practically completed. The design of car which has been submitted is on the Nottingham pattern, with accommodation for 22 passengers inside and 36 on the top. The question of providing the power has been under the consideration of the Electricity Committee, and it is proposed that the company shall pay a minimum price per quarter from May 1, whether the cars are then running or not. The enquiry by the Light Railway Commissioners into the application for sanction to make extensions is expected to be held at an early date, and a conference of the local authorities has been summoned to consider the proposals.

**Bradford.**—Arising out of the discussion which took place at last week's meeting of the City Council with regard to the discretionary powers of the general manager of the tramways department to suspend or discharge employés, and the question which was then raised as to the possibility of an appeal to the committee, the matter came up for consideration at Monday's meeting of the Tramways Committee. Special reference was paid to the interpretation of Rule 9 of the tramway regulations, which deals with the manner in which employés may be dealt with. Eventually the committee decided to allow the principle of appeal to the committee in cases of dismissal, and a sub-committee, including the chairman and deputy-chairman, was appointed to formulate rules under which appeals may be entertained by the committee. A proposal having been made that instead of each department of the Corporation in the town hall being connected separately with the National Telephone Company's system in Bradford it would be more economical if a central bureau were established in the town hall and the various departments of the Corporation connected with this bureau, a sub-committee considered this proposal and conferred with Mr. Spencer, the manager of the tramways, who had recently established a telephone system over the Bradford tramways, with a central office. Eventually the matter was adjourned for Mr. Spencer to present a report on the project. The town clerk and city treasurer have been instructed to prepare a scheme for the equitable distribution of administrative charges among the various departments.

**Wellingborough.**—The British Electric Traction Company's scheme for tramways in Wellingborough and the vicinity was again before the Irthlingborough District Council the other day. The clerk reported that in reply to his communications he had heard from the Higham Ferrers Council that that body had decided to support the Tramways Bill and withhold consent to the provisional order asked for on behalf of Mr. C. P. Harvey. From Rushden the reply was that the Council had not yet finally decided, but did not consider a conference necessary. The Council decided, that if the company would extend the tramlines to their district, they would support the scheme. At the meeting of the Raunds Urban District Council Mr. Paris, of the British Electric Traction Company, Limited, was introduced. Mr. Paris stated that the reason the company had not proceeded with the Tramways Bill of 1900 was because of the depression which set in about two years ago, and the difficulty experienced in getting the capital for the carrying out of a scheme that required £300,000 or £400 000. The company therefore decided to cut the scheme down by excluding Finedon and Irthlingborough so as to reduce the expense to manageable limits. These towns might be added in the extension of the present scheme later on. With regard to Raunds, the provisions of this Bill were the same as in the previous Bill. In reply to a question, Mr. Paris said the tramlines would be laid as far as Irthlingborough Station. The company had no power to supply electric light, but would provide power in bulk. On the retirement of Mr. Paris, the Council briefly discussed the matter and decided not to oppose the Bill.

**Swansea.**—The statutory public meeting of ratepayers for the purpose of considering the proposed Corporation Bill was held at the Guildhall last week, and the result of nearly three hours' debate was the approval of the Bill, with the exception of the sections relating to the proposed acquisition of powers to compulsorily acquire the existing tramways system within the borough. A demand was made for a poll. Dealing with the tramways clauses, the town clerk referred to the unsuccessful High Court action of February last for a declaration as regarded certain sections in the Swansea Improvements and Tramways Act, 1882, the result of which was that the Corporation now had

Digitized by Google

no power to acquire the whole of the existing tramways till pretty well the end of the present century, notwithstanding that Section 43 of the General Tramways Act, 1870, provided for the purchase of the tramways company undertaking after a period of 21 years. Purchase in that case meant the cost of construction less depreciation. There was no question of goodwill. As a matter of fact, the question of improvements was not involved in any shape or form. The present Bill provided that in the event of purchase the Corporation must grant a lease to the company for 21 years, the lease to be agreed between the Corporation and the company, or, failing agreement, the terms to be decided by the Board of Trade. He deemed it his duty to point out that now was the time for a decision to be arrived at regarding purchase. Several speakers joined in the discussion, the chief objection to the tramways apparently being that the undertaking was a speculative one. A satisfactory trial run has been made on the new section from the old terminus at Morriston through Woodfield-street and Clydach-road up to the end of the new route near Ynisfrigan.

## LIGHTING AND GENERAL.

**Windsor.**—The Town Council have decided to oppose the application for an order for an extension to Clewer.

**Batley.**—On Sunday the electric light installation in Zion Church and schools was used for the first time. The cost of the installation amounted to £240.

**Kirkcaldy.**—It is reported that the Town Council have received sanction to borrow £30,000 for works connected with the electric supply undertaking.

**Norwich.**—Application is to be made for loans of £30,000 for the purposes of the electricity undertaking to Sept. 30, 1907, including £6,400 for a turbine engine.

**General Nogi's Report.**—Amongst the spoil at Port Arthur we find enumerated the following: searchlights, 14; telegraph apparatus, 15; telephone apparatus, 134; signalling apparatus, 5.

**Bedwellty.**—The Guardians have adopted the specification and estimate of Messrs Herbert, Lewis, and Fletcher, Cardiff, for the proposed installation of electric light at the workhouse.

**St. Andrews.**—Further consideration of the street-lighting by electricity has been postponed until the report has been received of a deputation about to proceed to Edinburgh and Dalkeith.

**Industrial Storage Battery Syndicate, Limited.**—The liquidator is prepared to sell by tender the whole of the assets and undertaking of the syndicate in one lot. Particulars appear in another column.

**Woking.**—The clerk reported that the electric supply company have given notice of their intention to apply to the Board of Trade for power to extend the area of their supply to the urban and rural districts of Chertsey.

**South London Electric Supply Co.**—The company reports having sold during the quarter ended Christmas last 2,546,868 units, realising £21 760. The figures for the corresponding quarter in 1903 were 2,009,230 units, realising £18,230.

**Croydon.**—The County Council intend to oppose the Bills being promoted by the Administrative County of London and District Electric Power Company, the County of London Electric Supply Company, Limited, and the South Suburban and Croydon Gas Companies.

**Ashton.**—The Guardians have authorised their Electricity Committee to consult an electrical engineer with a view to an estimate being prepared showing the probable cost of engines, dynamos, etc., required to generate electricity for lighting purposes at the workhouse.

**Holyhead.**—Sanction has been received to the borrowing of £1,000 for the purpose of extending the electric lighting scheme into the outskirts of Holyhead. The Holyhead Urban Council have already borrowed £12,700 for the electric lighting scheme and £3,300 for the refuse destructor.

**Telephone Posts on Commons.**—The Postmaster-General is to receive a deputation on the 26th *re* the disfigurement of many commons and open spaces in the Home Counties by the erection of unsightly posts and wires in connection with the telephone system of the General Post Office.

**Bedlington.**—The Northern Electric Supply Company have decided to proceed to lay their mains in the district as soon as favourable weather commences. The area to be covered by the company includes the large districts of Cambois, Sleekburn, Choppington, Guide Post, Barrington, and Bedlington Town.

**Private Bills.**—The Examiners of Private Bills have passed the following London Bills, to which there was no opposition at this stage: Administrative County of London and District Electric Power Company Bill, Charing Cross and Strand Electricity Supply Corporation (Power Supply), L.C.C. Tramways, and L.C.C. Building Acts.

**Electric Plant, etc.**—Messrs. Foot and Milne, Limited, Prince's-mansions, 66, Victoria-street, S.W., report the following recent contracts—viz., for electric lighting of Pembroke Dockyard, Netley Hospital, King Edward VII 's Sanatorium, and for the central stations and complete equipment of the towns of Saffron Walden and Newquay.

**Farnham.**—The Urban District Council have agreed to Messrs. Roberts and Co.'s application for a provisional order, on condition that the Council have power to purchase the undertaking, if desired, in 21 years, and that if the electricity is generated by power gas the chimney shaft be erected at such a height that it will not be a nuisance to the town.

**Brighton Telephones.**—The General Purposes Committee have refused to grant the National Telephone Company permission to place their wires underground. The application before the committee was intermingled with a proposal for the relief of the unemployed, but the committee had no difficulty in seeing an old question under this new guise.

**Isle of Wight.**—The Shanklin Urban District Council have given the Isle of Wight Electric Light and Power Company, Limited, another three years' contract for the public lighting, the original contract having expired December, 1904. The Parish Council of Bonchurch have also extended the agreement for another five years from last summer.

**Marconi Wireless Telegrams.**—The Marconi Company have entered into an agreement with the Oceanic Steam Navigation Company, Limited (White Star Line), for the equipment of six of the White Star Line vessels with Marconi wireless apparatus. The names of the vessels to be fitted are "Oceanic," "Celtic," "Baltic," "Cedric," "Majestic," and "Teutonic."

**Barmouth.**—At the next monthly meeting of the Urban District Council, a vote will be taken on the question of adopting or rejecting the electric light scheme. At present the town is called upon to provide the money, and an electric lighting company undertakes to carry the project through and to maintain the same, subject to the option of transfer on certain terms.

**Kensington.**—Notices from the undermentioned electric lighting companies relative to proposed extensions of their mains in the borough have been agreed to: Kensington and Knightsbridge Electric Lighting Company, Limited, Kensington-square; Notting Hill Electric Lighting Company, Limited, Lansdowne-crescent; Brompton and Kensington Electricity Supply Company, Limited, Hollywood-road.

**Westhoughton (Lancashire).**—The Urban District Council have signed an agreement with the Lancashire Electric Power Company for supply of electrical energy in bulk for all purposes. It is expected that the supply will be forthcoming in about four months, and that a very considerable demand will arise for electrical energy for power purposes in this important coal-mining and manufacturing district.

**Stock Exchange.**—Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to the Cape Electric Tramways' further issue of 11,222 shares of £1 each, fully paid, Nos. 480 001 to 491,222; and to allow the Commercial Cable Company's further issue of £289 000 sterling 500-year 4 per cent. debenture stock (redeemable) to be quoted in the official list.

**Electrical Engineers' Ball.**—The dance of last year having proved so great a success, it has been decided to hold the next one on Friday, Jan. 27, at the Hotel Cecil. The following gentlemen form the executive committee: Messrs. J. E. Kinsbury, R. J. Wallis-Jones, W. Geipel, M. F. Roberts, and Percy Swan. Mr. R. Hammond is the hon. treasurer, and Messrs. A. M. Sillar and H. Alabaster will act as hon. secretaries.

**Surbiton.**—The District Council have sealed an application to the Board of Trade for a provisional order to put in force the Electric Lighting Acts, 1882 and 1888 and the Electric Lighting (Clauses) Act, 1899, and to extend the limits of supply for electricity for all public and private purposes to that part of the urban district of Surbiton which is not included in the area of supply as defined by the Surbiton Electric Lighting Order, 1891.

**Luton.**—In his last report Mr. Cook, the electrical engineer, states that during the last month 31,333 units were generated, an equivalent of 326 8-c.p. lamps and seven motors of 54 h.p. connected, making a total of 228 consumers with 13 855 lamps and 70 motors of 256½ h.p., and that the units generated showed an increase of 51 per cent. over the number generated during the corresponding period of last year, and that at the present time applications were in for 500 additional lamps and motors of 200 h.p.

**Manchester.**—At the last meeting of the Parliamentary Committee of the City Council the city surveyor reported on the plans deposited in connection with an application for a provisional order to authorise the Lancashire Electric Power Company to supply electricity for public and private purposes within the rural district of Barton-on-Irwell. Power is sought to construct works, acquire land, make charges, lay electric lines, and for other purposes. We understand that the committee will recommend the City Council to oppose the order.

**Johannesburg.**—The whole of the overhead telephone cables are to be laid underground. The town has been mapped out in telephonic areas, and early in the year the reconstruction will commence. The cables will contain from 612 to 104 paper-insulated wires, the whole cable being contained in a lead tube laid in earthenware ducts of 3½in. diameter. The length of single ducts is approximately 50 miles, forming a conduit measuring about seven miles. The length of cables is 13 miles, containing some 5,300 miles of single copper wire.

**Measuring Instruments and Switchgear.**—The Union Electric Company, Limited, 151, Queen Victoria-street, E.C., have taken over the electrical department of the firm of Messrs. Moul and Co., of 76 8, York-street, Westminster. This department specialises in the best qualities of (*a*) measuring instruments, both for technical and scientific purposes, constructed by the world-famous firm of Hartmann and Braun; (*b*) automatic and hand switches, and cut-outs, lightning arresters, etc., for every class of current, and for voltages up to 40,000. Mr. H. E. Moul has joined the staff of this company as its technical manager.

**Coventry.**—We regret to note that the Town Council on Tuesday last referred back to the Electric Light Committee a proposal to increase the salary of Mr. J. A. Jeckell, the borough electrical engineer. It was admitted that he had converted a failure into a commercial success, and yet the councillors quibbled about the amount of the proposed increase and the length of Mr. Jeckell's service. Such quibbling over the remuneration of capable employés who have proved their worth brings great discredit on municipal management. We trust that at an early date the Electric Light Committee will bring forward and carry an exactly similar motion.

Digitized by Google

**London Gazette.**—The partnership between Bernard Sherman, Francis Heron Rogers, and Dallas Henry Muston, carrying on business as electrical engineers and telephone specialists at 16 and 17, Devonshire-square, Bishopsgate-street Without, London, has been dissolved by mutual consent. A public examination will be held at Swansea on Feb. 8, 1905, *re* Henry Coles, electrical engineer, 10, York-street, Swansea. A first and final dividend of 1s. 5½d. in the £ has been declared in the estate of William Wenham, electrical engineer, 5, Century-buildings, London-road, Croydon, Surrey.

**Lichfield.**—The City Council have sealed an agreement with Messrs. Foote and Milne, Limited, of Princes-mansions, 66, Victoria-street, who are applying for a provisional order for the district. The maximum price is fixed at 7d. per unit, but a clause is inserted to the effect that until purchase and transfer to the Corporation as provided in the agreement the maximum price to be charged for energy under the new order shall not, except with the consent of the Corporation, in writing, exceed the following—viz.: to the Corporation for lighting, 5d.; to the Corporation for power, 2½d.; to ordinary consumers for lighting, 6d.; and to ordinary consumers for power, 3d. per Board of Trade unit.

**City Trade Branch.**—The Canadian Government have opened a City branch office at 73, Basinghall-street for the special convenience of business men. This office is well supplied with Canadian books of reference, directories, reports, and other sources of information, which will be kept up to date, and in due course it is proposed to instal a small display of the leading Canadian products and resources. Information will be supplied regarding Canadian trade, the products and resources of the Dominion, and other matters relating to Canada, to any persons who may wish to make use of the facilities possessed there, and personal interviews can be arranged by appointment when desired.

**King's Lynn.**—Mr. F. W. Savage having resigned the chairmanship of the Electricity Committee, Mr. Gemmell has been appointed in his stead. The engineer's last report states that since the last meeting applications have been received for 366 additional lamps of 8 c.p. (or equivalent), making a total of 20,334 from private consumers and that there are now 502 private consumers, being an addition of 17, the additions including one motor of 5 h.p. The following figures are added: Unit generated, November, 1904 57,081 (1903, 53,031); total units sold to private consumers (light and power), 28,295 (22,627); units sold at power rates, 10 228 (6,790); cost of fuel, stores, repairs, and wages at station, £141 (£132. 16s. 10d.); cost per unit generated, 0·5928d. (0·6012d.); wages of lamp-lighters and outside staff, £21. 3s. 5d. (£23. 13s. 10d.). One of the switchboard attendants has resigned, and the engineer has been authorised to fill up the vacancy.

**Derby.**—The returns for the tenth year of the Corporation's electricity undertaking show substantial progress. The increased demand for electricity and the gradual reduction of cost during the past three years are illustrated by the following: Year 1901-2—consumers 870, lamps 75,972, number of units sold 1,081,487, total cost per unit 2·07d.; 1902-3—consumers 1,002, lamps 87,502, number of units sold 1,287,619, total cost per unit 1·56d.; 1903-4—number of consumers 1,240, lamps 106,790, number of units sold 1,490,611, total cost per unit 1·45d. The amount of loan sanctioned was £196,048. Of this, £159,369 has been borrowed at the rate of 3 per cent. The amount repaid is £28,836. The capital expenditure at the ends of the ninth and tenth year was respectively £159,657 and £180,386; revenue from electricity supply, £17,137 and £18,950; revenue from meter rents and other sources, £1,319 and £1,504; total revenue, 1902-3, £18,456; 1903-4, £20,454; total costs, £8,389 and £8,986; gross profit, £10,067 and £11,468; percentage of gross profits to average capital, 6·50 and 6·57 per cent.; interest on loans, less interest receivable, £4,430 and £4,937; sinking fund, £5,040 and £4,814; percentage of ditto to average capital, 3·25 and 2·76 per cent.; financial result after providing for interest and sinking fund (surplus), 1902-3, £597; 1903-4, £1,717.

**Borough Theatre, Stratford.**—As already noted, some 12 months ago an entirely new electrical installation was put into this theatre and considerable improvement in the general lighting has since taken place. Consequently advantage has been taken by the management for the introduction of some novel electrical effects during the performance of the successful pantomime now running—"The Forty Thieves"—which admirably lends itself to this purpose. Perhaps the best effect is produced in the "Interior of the Cave" scene, in the centre of which a large fire is seen burning upon the altar to the god of Avarice. The appearance of fire is effected by the use of strips of red and yellow silk kept in upright motion by means of a motor fan situated in the altar beneath, while the rays of two powerful red arc lamps placed below the fan are projected on the moving silk strips. From the roof of the cave are suspended a number of swinging red 5-c.p. incandescent lamps. These are kept in a continuous state of "twinkling" by means of a break switch, and give the unique appearance of a swarm of fire flies floating about the stage. The change in this scene when the cave is opened, disclosing a beautiful green landscape in the distance, is particularly well executed. In the last grand tableau the scene is lighted by 12 powerful arc lamps mounted on the stage and two 50-light candelabra placed at the foot of the great staircase. To those of our readers who take an interest in electrical effects and theatre lighting generally we recommend a visit to this popular house of entertainment during the run of the present pantomime.

**Harwich.**—The report of the Lighting Committee dealing with a proposed scheme of electric lighting for Harwich was again discussed at the last Town Council meeting. It stated that the committee had considered the question of utilising the Harwich electric lighting order granted to the Corporation in 1892, as the Board of Trade had threatened to cancel it unless its provisions were put into effect. The advice of Messrs. Medhurst and Lloyd, electrical engineers, of Westminster, was obtained, and the report dealt with the provision of a refuse destructor in connection with the electric lighting scheme. The recommendation of the Lighting Committee was to the effect that tenders should be invited from responsible contractors, who would be prepared to enter into an agreement with the Corporation to carry out the scheme, and thereafter to take a lease of the undertaking for a term of 25 years, at a rental equal to £6 per cent. upon the total cost thereof, the contractors being responsible for the maintenance of the works and plant during the above period, and the Corporation having power to determine the lease at the end of seven, ten, or fourteen years. Under such lease the contractors would not be allowed to charge more than 6d. per unit for lighting and 3d. per unit for motor. The committee further recommended that, provided the town clerk was satisfied that the interests of the borough could be secured, and that no outlay for electric lighting would be requisite from the current rates, either for interest upon the money borrowed or for the repayment of capital, the Board of Trade be asked to consent to the proposed scheme, and authorise the Corporation to borrow £22 000 for electric lighting, and a further sum of £3,000 for the refuse destructor. After discussion it was decided that the Board of Trade be asked to extend the time for utilising the Harwich electric lighting order until the fate of the Dock Bill was known.

## PROVISIONAL PATENTS, 1904-5.

DEC. 31.

**29353. Improvements in rotary converters for electric currents.** Louis John Hunt and the Sandycroft Foundry Company, Limited, 6, Lord-street, Liverpool.

**29354. Improvements in apparatus for transmitting electric signals or impulses.** Gustav Grabosch, 6, Lord-street, Liverpool.

**29363. Improvements in and relating to electrical measuring instruments.** Henry Harris Lake, 7, Southampton-buildings, Chancery lane, London. (Vittorio Arcioni, Italy.) (Complete specification.)

**29368. Improvements in and connected with induction coils.** Herbert Watson Sullivan, 23, Southampton-buildings, Chancery-lane, London.

**29369. Improvements in and connected with electric relays and recorders.** Herbert Watson Sullivan, 23, Southampton-buildings, Chancery-lane, London.

**29377. Improvements in fuses for electrical circuits.** Michael Birt Field and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

**29386. Improvements relating to electrical generators having double T-shaped armatures.** Franz Gutzmann, 322, High Holborn, London. (Complete specification.)

**29397. Improvements in and relating to pendant electric fixtures.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Walter Lincoln Bradshaw, Augustus Keough, Martin Keough, and James Keough, United States.) (Complete specification.)

**29401. Improvements in and relating to pendant electric fixtures.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (Walter Lincoln Bradshaw, Augustus Keough, Martin Keough, and James Keough, United States.) (Complete specification).

**29408. Improvements in current distributors for the electric ignition devices of internal-combustion engines.** Louis Renault, 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Sept. 23, 1904, being date of application in France.) (Complete specification.)

**29417. Electromagnetic machinery.** David Cook, 165, Queen Victoria-street, London.

**29422. Improvements relating to electrical apparatus for transmitting and receiving signals.** Arthur Trevor Dawson and George Thomas Buckham, 7, Southampton-buildings, Chancery-lane, London.

**29435. Improvements in alternating-current collector motors.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens-Schuckertwerke, Germany.)

**29436. Improvements in alternating-current collector motors.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (The Siemens-Schuckertwerke, Germany.)

**29437. Improvements in electrical ignition devices for internal-combustion engines and other purposes.** John Arthur Torrens, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**29438. Improvements in electrical measuring instruments.** James Hunter Gray, 58, Comeragh-road, West Kensington, London.

**29448. Improvements in and relating to arc lamps.** Oskar Konitzer, 27, Chancery-lane, London.

**29466. Apparatus or appliance for supporting a telephonic receiver and transmitter or analogous instrument.** William Henry Danson, 21, Cole-street, Borough, London.

**29487. Improvements in or relating to space telegraphy and apparatus therefor.** George Finlay Anderson, 111, Hatton-garden, London.

**29529. Improvements in telephone systems.** Felton Vollmer, Fife House, Kingston-on-Thames.

Digitized by Google

29504. **Improvements in and relating to galvanic elements.** Nicolaas Arnoldus Smits, 1, Broad-street-buildings, Liverpool-street, London.

29516. **A new or improved automatic circuit breaker or cut-out for overhead tramway systems.** Henry Gordon Turnell, 9, Regent-street, London.

29531. **Improvements in electrical signalling apparatus.** Franklin S. Holmes, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, March 25, 1904, being date of application in United States.) (Complete specification.)

29532. **Improvements in electrical signalling apparatus.** Franklin S. Holmes, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, March 19, 1904, being date of application in United States.) (Complete specification.)

29533. **An improved electric circuit closer for fire-alarms.** John Elmer Bemiller and Emery C. Weisensale, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, May 7, 1904, being date of application in United States.) (Complete specification.)

29607. **Improvements in liquid resistances for controlling the current in electrometers and the like.** Bruce Peebles and Co., Limited, and Arthur Charlesworth Peebles, 34, Castle-street, Liverpool.

29613. **Improvements in electrolytic meters.** George Hookham, 18, Southampton-buildings, Chancery-lane, London.

29627. **Improvements in electrical fire-alarm or other call apparatus.** Charles Shore and Charles Heap, 6, Bank-street, Manchester.

JAN. 2.

40. **Improved plough for use on the electric conduit for tramways or light railways.** James Jonas Attridge, 43, Lincoln-avenue, Bournemouth.

66. **Improvements in electric switches.** Charles Smith, 33, Chancery-lane, London.

98. **Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JAN. 3.

123. **Improvements in apparatus for and process of electric welding and other metal-working operations.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Thomson Electric Welding Company, United States.) (Complete specification.)

136. **Improvements in transformers.** Frank Conrad, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 20, 1904, being date of application in United States.) (Complete specification.)

JAN. 4.

167. **Improvements in the insulation of wires conducting electricity.** Herbert George Longford, Woodcote, Weather-oak-road, Sparkhill, near Birmingham.

171. **Improvements in or relating to electromagnets used with cranes for lifting rails, ingots, or the like.** Steel, Peech, and Tozer, Limited, and Henry Edward Bowen, Bank-buildings, George-street, Sheffield.

177. **A device for notifying to an individual when an electric circuit fails, and especially for notifying the driver of a motorcar when the rear electric light fails.** Ernest Hardy Pickford, Moorgate, Rotherham.

184. **Compensated single-phase alternating-current commutater motor.** Engelbert Arnold and Jens Lassen la Cour, 34, Castle-street, Liverpool. (Date applied for under Patents Act, 1901, Jan. 4, 1904, being date of application in Germany.) (Complete specification.)

185. **Arrangement for leading in and taking off the armature current of compensated single-phase commutator motors.** Engelbert Arnold and Jens Lassen la Cour, 34, Castle-street, Liverpool. (Complete specification.)

191. **Improvements in adjustable flexible connections for gas-pendants, fluids, steam, or electrical conductors.** Samuel Quincey and Charles Harrison, 136, Kentish Town-road, London.

209. **Improvements in electromagnetically controlled fluid-pressure motors.** Ernest de Merindol Malan, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

210. **Improvements in electric arc lamps.** William Reginald Ridings, Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London.

211. **Improvements relating to electric arc lamps.** La Société Leperche et Cie., 40, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 2, 1904, being date of application in France.) (Complete specification.)

JAN. 5.

256. **An improved solution for the formation of accumulator plates.** Max Lorenz and Henry Crane, 81, High Holborn, London.

254. **Improvements in electric lighting.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

255. **Improvements in electric resistance units.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

256. **Improvements in magnetic separators.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

257. **Improvements in electric arc lamp electrodes.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

JAN. 6.

311. **Improvements in apparatus for testing electrical resistances.** John Bernard West, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

313. **An improved device for attaching electric conductors to terminals.** Alexander Miller, 4, South-street, Finsbury, London.

315. **Improvements in or relating to plates for secondary batteries.** William Phillips Thompson, 322, High Holborn, London. (Pflüger Accumulatoren-Werke Act.-Ges., Germany.) (Complete specification.)

329. **Improvements in and relating to electric power-transmitting mechanism.** The British Thomson-Houston Company, Limited, and Bernard Hopps, 83, Cannon-street, London.

JAN. 7.

343. **Improvements in apparatus for converting multiphase current into continuous current.** Bruce Peebles and Co., Limited, and Jens Lassen la Cour, 34, Castle-street, Liverpool. (Complete specification.)

352. **Protective apparatus for alternating-current circuits.** Harry Phillips Davis and Frank Conrad, The Westinghouse Patent Bureau, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 20, 1904, being date of application in the United States.) (Complete specification.)

354. **Improvements in electrical measuring instruments.** Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria-street, London.

368. **Improvements in vapour electric apparatus.** The British Thomson-Houston Company, Limited, and John Gray, 83, Cannon-street, London.

369. **Improvements in vapour electric apparatus.** Alexander McLeod Jackson, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 9, 1904, being date of application in United States.) (Complete specification.)

370. **Improvements in vapour electric apparatus.** Osias Otto Kruh, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 9, 1904, being date of application in United States.) (Complete specification.)

374. **Improvements in electrometers for single-phase current.** Akt.-Ges. Brown, Boveri, und Co., 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Jan. 8, 1904, being date of application in Switzerland.) (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published Jan. 19, 1905.*

1904.

4075. **Construction of electric switch.** Markt.

4925. **Electric bell-pushes.** Ross.

4944. **Arc lamps and carbons therefor.** Russo.

5164. **Electric arc lamps.** Crompton and Co., Limited, and Hodgson.

15691. **Advertising by means of electric lamps.** Mead.

24399. **Electric tools.** Schiemann.

25112. **Electric light systems.** Lake. (Gould.)

25592. **Electric switches.** Hunter.

26043. **Submarine telegraphy.** Kitsee.

26097. **Magnetic clutches.** Eastwood. (Date applied for under International Convention, April 1, 1904.)

*To be published Jan. 26, 1905.*

1904.

131. **Regulation of electric currents.** La Cour. (Date applied for under International Convention, Jan 5, 1903.)

552. **Microphones for telephonic apparatus.** Bassompierre and Dardeau. (Date applied for under International Convention, Jan. 15, 1903.)

2063. **Static electrical machines for lighting gas, ether, and the like.** Nehmer.

2456. **Machines for treating filaments for electric lamps.** British Thomson-Houston Company, Limited. (General Electric Company)

4234. **Electrical measuring and indicating instruments.** Elphinstone.

4376. **Electricity meters.** Tourtel and Tourtel Manufacturing Company, Limited.

4771. **Controlling alternating-current electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

5118. **Electrical radiators.** Dowsing.

Digitized by Google

**5664. Base or wall block to facilitate the erection of electric light fixtures and provide better insulation at their bases.** Ewart.

**7267. Electrical switches.** Bornand.

**9306. Apparatus for the automatic regulation of electric currents for charging storage batteries.** Akt.-Ges. Brown, Boveri, und Co. (Date applied for under International Convention, April 23, 1903.)

**19589. Electric meters.** Duncan. (Date applied for under International Convention, Dec. 29, 1903.)

**21894. Regenerative dry batteries.** Gregory.

**24200. Electric switches.** Clark.

**26157. Electric arc lamps.** Nusch. (Cotis.)

**26260. Electric arc lamps.** Sipe.

**26367. System of wireless telegraphy.** Thompson. (Ges. für drahtlose Telegraphie.)

**26449. Insulators for electric wires.** Flynt and Maiden.

*To be published Feb. 2.*

1903.

**24516. Receiving or detecting and recording apparatus for telegraphic and other electrical purposes.** Armstrong and Orling.

1904.

**618. Electric railway systems.** British Thomson-Houston Company, Limited, Sporborg, Carter, and Cubitt.

**1081. Telephone adapted for use by partially deaf persons.** Nathan and Newland.

**1484. Controlling electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**1513. Shade carrier holder for bayonet or screw electric glow lampholders.** Escaré.

**3147. Electric switches for the igniting circuits of multiple-cylinder explosion motors.** Talbot and Mobley.

**5308. Electric contact devices such as resonance relays for telephone systems.** Pedersen.

**5360. Electric lampholder.** Hirst and Collings.

**6039. Controlling valves for use in connection with pneumatic brake systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**6067. Adjustment of magnetic compasses.** Gruby.

**6425. Electric candle fittings.** Banks.

**8262. Telephones for use in dictating correspondence for exchange call-room, for personal use, and for other like uses.** Port.

**9831. Means for the regulation of electric circuits for the production of constant current or constant potential or of both.** James. (Northern Electric Company.)

**11274. Telephone selecting systems.** Watkins.

**21796. Controllers for electric motors.** Churchward. (Date applied for under International Convention, Oct. 10, 1903.)

**23797. Temperature compensating devices for electrical measuring instruments.** Bristol.

**25295. Electric accumulators.** Jungner.

**25165. Device for distinguishing between the poles of an electric circuit.** Prested.

**25911. Couplings for the driving and driven members of dynamos, turbines, hydro-extractors, and other high-speed machinery.** Jebsen.

**26538. Electrical fuse-boxes, ceiling roses, wall plugs, and the like.** Herbert.

**26696. Apparatus for wireless telegraphy or telephony.** Eisenstein.

**26757. Signalling bells worked by electrically-controlled compressed air or other gas.** Siemens Bros. and Co., Limited. (Siemens und Halske Act.-Ges.)

**26820. Electrical switches and cut-outs.** Dorman, Smith, and Baggs.

**26920. Arc light electrodes and methods of making the same.** Lindsay. (Date applied for under International Convention, Dec 10, 1903.)

**27010 Alternating electric current frequency changers.** Kruh. (Date applied for under International Convention, Dec. 12, 1903.)

**27095. Electric telephony.** Adams-Randall.

## NOTES.

**The Engineering Standards Committee.**—It is announced that Mr. James C. Inglis, general manager of the Great Western Railway, has been nominated by the council of the Institution of Civil Engineers as one of their representatives on the Engineering Standards Committee, in the place of the late Mr. John Allen McDonald, engineer-in-chief of the Midland Railway.

**Conduit Slot.**—As briefly noted in a recent issue, the Board of Trade has acceded to the application of the London County Council for an alteration in the width of the conduit slot for their tramways. In the report presented to the Council on Tuesday the Highways Committee state the Board has sanctioned a slot having a width of 1in. instead of $\frac{3}{4}$in. for the St. John-street and Rosebery-avenue route, thus introducing the new type of slot on the Council's northern system.

**Brighton Corporation Telephone Department.**—To celebrate the first year of its existence, this department held a successful conversazione at the Old Ship Assembly Rooms on the 13th inst., under the auspices of the Mayor (Alderman F. Blaker). The staff and their numerous friends were entertained to a capital programme, including vocal and instrumental music, dancing, etc. Naturally, the telephone undertaking itself was brought into requisition in adding to the attractions of the evening, as, by permission of Mr. Councillor Beryl, the proprietor of the Theatre Royal and a member of the Telephone Committee, the music of "The Girl from Kay's" could be heard on the electrophone, and was greatly appreciated. Mr. D. J. Barnes, the popular manager of the department, with Mrs. Barnes, ably did the honours of the evening.

**Wireless Telegraphy in the Navy.**—It is reported that previous to the Atlantic fleet leaving for its first cruise, each of the battleships will be provided with an installation of wireless telegraphy apparatus, the Admiralty having decided to take this step as the result of the improved reliability of wireless telegraphy in the British fleet. Owing to the improved apparatus, it is expected that ships on detached service will be able to keep in touch with the flagships of their respective squadrons at a much greater distance than was possible a year ago, thus considerably increasing the tactical area of the fleet's movements. It is also stated that the Admiralty intend to instal the system on several cruisers, thus enabling them to make reports direct to their flagships while maintaining their position in the "scouting line," which can then be far out of the present visual signalling range.

**New Publications.**—Messrs. Whittaker and Co. will shortly publish a new book entitled "The Insulation of Electric Machines," by H. W. Turner and H. M. Hobart. This work is the result of several years' practical experience with insulating materials and of careful study of their insulating properties.—"The Colliery Manager's Pocket-Book for 1905," by R. A. S. Redmayne. (London: "Colliery Guardian" Company, Limited. 2s., 3s., and 4s. 6d.) In addition to the usual almanac and diary features, this publication contains special articles upon "Deep Mining," "Coal-Cutting by Machinery," "The Coalfields of the United Kingdom," and a review of the chief events of the year, besides a quantity of statistics.—"Second Stage Magnetism and Electricity," by R. W. Stewart. (London: University Tutorial Press, Limited. 3s. 6d.) This treatise has been brought up to date, and covers all the requirements of the Board of Education's advanced examination.

**Railway Electrification.**—After having virtually decided upon the electrification of the Springs-Randfontein section of the Central South African Railways, it appears that the Inter-Colonial Council have shelved the project, some of their number being apprehensive about its success. This is rather surprising after the scheme which had been evolved by the authorities in consultation with Messrs. Mordey and Dawbarn, and particularly as a large firm of contractors was prepared to undertake the work and accept payment by instalments out of the profits. This arrangement, it is estimated, would have repaid the cost of conversion in little more than eight years without any capital being raised. Railway affairs in South Africa have become somewhat involved of late, judging by reports in the daily Press, but it is to be hoped that the electrification of the line in question will not be long delayed, as the figures reported in our issue of the 16th ult. indicate that the scheme is a promising one.

**Southern Nigeria.**—It is reported that Captain J. P. Moir, D.S.O., R.E., who has been appointed by the Colonial Office to take charge of the telegraph construction in Southern Nigeria, is about to depart for Lagos. He will be followed in a fortnight by a party of non-commissioned officers, who will superintend the working parties on the line of construction. After conferring with the commissioner at Lagos, Captain Moir will make a survey of the line to be followed. The actual work of construction will begin in March with the lines on the delta of the Niger, so that this portion of the work in the swampy country can be got well in hand before the rains commence. The work involves the erection of some 400 miles of telegraphs, and will occupy a year. When completed, Calabar and Lagos will be connected by land wires independent of the cables. From a point on the line between Calabar and Bonny the line will be carried to Onitsha, on the Niger, and thence to Benin, Warri, and Lagos, where it will effect a junction with the telegraph to Kano and Sokoto.

**Wireless Telegraphy.**—In replying to the brief discussion on his interesting paper, "Wireless Telegraphy and War Correspondence," read before the Society of Arts on the 18th inst., Captain Lionel James intimated that one of the reasons which prompted him to select the De Forest system was that communication was more rapid by that than any other. He stated the figures as 30 or more words per minute, as against the 10 or 12 of the other systems he had investigated. As an avowedly non-technical man, Captain James did not discuss the distinction between receiving messages by sound-reading instruments and recording instruments, but Mr. Cuthbert Hall, the managing director of Marconi's Wireless Telegraph Company, remarks in a communication to the *Times* that it is misleading to compare sound-reading instruments with recording instruments. He also states that the speed of his company's recording instruments is very much more than 10 or 12 words per minute, and that the speed of their sound-reading instruments is only limited by the capacity of the operator at the receiving station to read by sound. If, says Mr. Hall, an operator capable of reading by sound at the rate of, for example, 100 words per minute were available, there would be no difficulty in communicating at that speed by the Marconi system over 10 times the distance covered in the Far East operations described by Captain James.

**Telegraphic Achievement.**—The Washington and Sydney Observatories, with the telegraph administrations concerned, co-operated in the dispatch of time signals on New Year's Eve between the two observatories. An official of the Sydney institution now reports as follows: "The first set of signals were received satisfactorily, the 3 p.m. contacts being recorded here at 3 hours and 3·57 seconds. Of the second set only 30 signals were received altogether, the 4 p.m. signal reaching here at 4 hours and 3·66 seconds.

Digitized by Google

The third set was satisfactory, the 5 p.m. signal reaching here at 5 hours 2·76 seconds. The fourth set was satisfactory, the 6 p.m. signal reaching here at 6 hours 2·55 seconds. The final mean was 3·14 seconds. Cutting out the second set, the mean gives 2·90 seconds. This concludes the arrangements at present existing, and the rapid time in sending the great distance separating Sydney and Washington, over 12,000 miles, is a triumph to the electrical departments of the States concerned. With many thanks and every good wish for the New Year." The general manager of the Pacific Cable Board, in communicating this information, adds that the signals through the Vancouver-Fanning cable, the longest cable span in the world (3,457·76 nautical miles), were sent by automatic apparatus, and were recorded as they passed at the Vancouver station on an instrument placed in the artificial line which balances the cable for the purpose of duplex working.

**The Orling-Armstrong Electro-Capillary Recorder.**—At the Royal Institution on Friday last the Orling-Armstrong recorder as adapted for use on submarine cables was exhibited. In order to obtain high speeds in such working, it is imperative that the recorder used should readily respond to small changes in potential difference. In this respect the Orling-Armstrong recorder working on the electro-capillary principle has several distinct advantages. It is free from self-induction faults, and, owing to the small mass of the moving parts, the mechanical inertia is very slight. With the recorder shown the full range of movement in the mercury thread was only ·5mm. The distortion of signals due to the weight of the siphon recorder coil can easily be traced by comparing the records produced by such instruments. For instance, the space between the two letters "U" and "V" is well defined on the capillary slip, whilst that between the same letters on the siphon recorder slip can only be observed by a trained eye, and that only from the general character of the line extending from the dash of "U" to the last dot of "V." The same instrument working on the electro-capillary principle is also useful for land lines in preventing to a large extent the interference caused by leakage. This leakage increases with the E.M.F. used on the lines, and with the Orling-Armstrong recorder the E.M.F. is very small. Sample records were shown, and it was claimed that with these recorders impulses at the rate of 1,000 per second could be received when the actuating potential difference was no more than one millivolt.

**Leeds Section.**—A paper on "Condensing Arrangements in Central Stations" was read last week before the Leeds Local Section by Mr. J. D. Bailie. The first part of the paper was of an elementary character, the reason of this being that the author considered that sufficient attention was not always given to the question of the most suitable type of condensing plant, or the general arrangement of the condenser itself and its accessories. Mr. Bailie emphasised the importance of the water supply as a primary consideration in the selection of the type of condenser. For example, if cooling towers were used, the surrounding atmosphere should be taken into account, as, the same water being used again and again, it might collect impurities from the atmosphere. He quoted an instance of some steelworks at Sheffield, where the chemical action resulting from this cause had converted the water into a corrosive medium. Generally, he found that, wherever practicable, condensing should be resorted to, and in many instances he thought it would pay to pump cooling water from considerable distances. Accessibility to the various parts of the condensing plant was another important factor. Examination should be systematic. Gauges should be fitted wherever desirable. Thermometer pockets and thermometers should be permanently fitted to the circulating suction and discharge connections and to the air-pump discharge. Logs should be kept of the quantity of circulating water passing, also of the several temperatures, and a look-out kept for leakage. In fact, tests of every principal part and function should be regularly made and studied, so that defects might be promptly detected and remedied.

**New Low-Temperature Phenomena.**—A lecture on this subject was delivered at the Royal Institution last week by Sir James Dewar. Having liquefied and then solidified hydrogen, Sir James directed his attention to helium, which is the only element that now resists the extreme forms of cold, and intimated a possible advance towards its ultimate subjugation. By means of Sir William Crookes's radiometer the lecturer then demonstrated the remarkable power of charcoal to absorb gases. Taking a radiometer with the bulb containing air, and connecting it with charcoal, reduced to the temperature of liquid air—minus 185deg. C.—the bulb immediately became a high vacuum, and the vanes revolved at a rapid rate. In another experiment phosphorus was placed in a small bulb above another filled with oxygen, both substances being quite dry. In this condition the phosphorus will not ignite. Then the oxygen was connected with charcoal chilled by liquid air. The bulk of it was absorbed by the charcoal; the phosphorus became gaseous and combined with the oxygen, and made the bulb luminous, showing that at the temperature of liquid air substances will combine chemically, even without moisture. Finally, the professor took a radiometer filled with helium, and on this charcoal cooled by liquid air had no effect. He then plunged the carbon into liquid hydrogen at the temperature of 20deg. C. absolute, representing about 456deg. of frost. Immediately the helium began to be absorbed by the charcoal, a vacuum was formed, and the vanes of the radiometer revolved. This suggests a further field of research, and a new means of separating from the air the rare gases recently discovered—argon, helium, neon, xenon, and krypton.

**Overhead Telegraph Wires.**—In the course of his recent paper before the Tramways and Light Railways Association, Mr. H. M. Sayers made the cogent statement that in the streets of some towns the only picturesque object visible is a neatly-constructed overhead equipment, and it certainly must be said that the æsthetes often call out with inadequate cause. At the same time one can appreciate the objections to the extensive use of overhead telegraph or telephone wires on open spaces. Early in last session the Postmaster-General sought power to dispense with the consent of the Conservators of Commons and Open Spaces, but, in consequence of the opposition evoked, the Bill was withdrawn. The General Post Office has, it is stated, since been active in endeavouring to attain the same end by obtaining the consent of the various highway authorities to the erection of overhead wires, with the result that the disfigurement of commons and places of unique attraction is proceeding at an increased rate, much to the alarm of those who are interested in preserving the natural aspect of open spaces and the amenities of picturesque districts. At the instance of the Commons and Footpaths Preservation Society, the Postmaster-General consented to receive a deputation yesterday, when representatives of the various open space societies and of numerous local authorities were expected to urge upon him that rural districts of special interest or beauty, and especially commons and open spaces, should be treated as sacred. It is proposed that in such cases alternative routes should be adopted, or the wires laid underground. Where no substantial addition to the cost is involved, these

Digitized by Google

suggestions are deserving of consideration; but we live in a commercial age, and sentiment has perforce often to be subordinated to utility.

**Royal Meteorological Society.**—The annual general meeting of this society was held last week, Captain D. Wilson-Barker, F.R.S.E., the president, being in the chair. The council in their report referred to the fact that during the summer the Admiralty had placed at the disposal of the Kite Committee H.M.S. "Seahorse" for the purpose of carrying on the kite observations off Crinan. The average height attained was about one mile. Mr. Richard Bentley, F.L.S., was elected president for the ensuing year. Captain Wilson-Barker delivered an address on "The Connection of Meteorology with other Sciences." He said that meteorology and astronomy were doubtless the first of the sciences to attract the attention of man. Which of the two exerts most influence on the well-being of humanity was a matter dependent on the position of the globe. In many regions people are but slightly affected by the weather, while the heavenly bodies—particularly the sun—exert an enormous influence on human life. Everywhere in Nature we find the effects of meteorological agencies. After speaking upon the effects of evaporation—winds, rain, ice, snow—and pointing out the influence of weather on animal life, vegetation, health, etc., he said that meteorology was a science deserving more attention than it received. He thought it ought to be recognised as a preliminary to the studies of geography, geology, and kindred subjects, and he considered that meteorological observatories might very well be fitted up in schools, and pupils taught to observe. This could be done at a small cost of time or money. The tendency at present was to particularise in all scientific work, but the true path to progress laid in keeping a comprehensive outlook on the whole field of investigation. The United States have devoted much attention to meteorology with most satisfactory results. He regretted that official help and encouragement were so deficient in this country. The difficult nature of meteorological problems should but serve as an incentive to their elucidation. The persistent observer gains much, not only in knowledge of the subject, but in the habits of close and accurate investigation which he insensibly acquires, and all workers in the field learn to appreciate the difficulties which confront their fellow-labourers, and to recognise the value of what has been done by the meteorological organisations of the world.

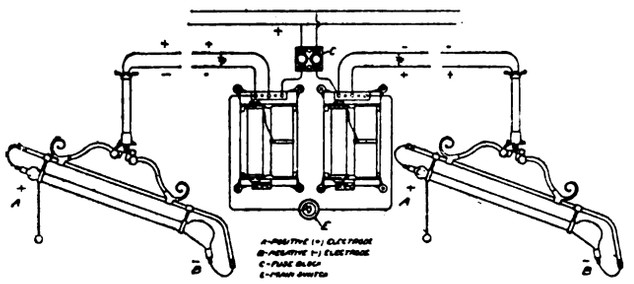
**Accidental Electrocution.**—The *Lancet* reports a discussion by the members of the London Clinical Society upon a case of accidental electrocution which caused gangrene of all the extremities. The deceased, a healthy lad aged 15½ years, was employed at the London Electric Supply Corporation's station in Blackfriars-road. The current is received at this station from Deptford at high pressure, the maximum being 10,000 volts. Transformers are located on both sides of the station, and those on either side are "alive" in turn. The lad mounted one of the "dead" transformers to dust some slabs of slate above, and in descending the iron plates on the soles of his boots caused him to slip on the iron of the transformer, and, overbalancing, his right hand came in contact with the main cable carrying the 10,000 volts. The current, it is imagined, passed through him for about 30 seconds, when a man, attracted by the flash of the escaping current, rushed over to the boy, who was rigid and apparently lifeless. Artificial respiration restored consciousness. When taken to the hospital he showed signs of shock, and all his limbs were gangrenous. His socks and boots were extensively burnt, and the latter were burnt through. On the third day his right arm was amputated at the shoulder joint. On the sixth day it was evident that the gangrene of the legs was spreading, and the patient's temperature was rising, so both legs were amputated. Two days later, however, symptoms of toxic infection appeared, and on the ninth day from the accident the boy died. The remarks made during the discussion by Mr. F. Aspinall, electrical engineer, suggested a new explanation of the cause of death. He stated that when an arc was formed, metals became volatilised, and he suggested that the inhalation of these vapours might prove fatal. It was stated in the course of the discussion that when an accident is accompanied by burning of the skin, the shock is usually less severe. Allusion was also made to the now well-recognised fact that the effect of a shock is dependent more upon the nature of the contact than the voltage. Dr. S. Jellinck (Vienna) recommended that in framing rules for the prevention of accidents in establishments where electricity is employed regard should be had not only to the tension of the current, but to the dielectric condition of the ground.

**The Franklin Institute.**—We have received a copy of this Philadelphian society's *Journal* for January, which contains papers on "The Telegraphone," by Dr. Z. B. Babbitt; "The United States Patent Laws: Historically Considered," by Mr. C. N. Anderson; "Physical Characteristics of Certain Bronzes for Steam Uses," by Mr. S. L. Kneass; "Saltmaking in the Far West," by Mr. E. Goldsmith; "The Bacterial Disposal of Sewage," by Mr. G. E. Hill; and other matters. Dr. Babbitt, after tracing the development of Poulsen's telegraphone, which has already been described in our columns, asks what influence it is destined to exert upon the social system, and himself answers the question in these notable terms: "The reproductions are true to the human voice either conversational or in song, and the day will come when every family will have records made at frequent intervals—from the child's first efforts at speech through an entire life; and families will prize these records as they do photographs; national bureaus will be established for the preservation of records of speeches of our public men and women; correspondence will be carried on by the use of the disc machine in preference to the present methods. Many business transactions are carried on daily over the telephone, and the day is at hand when telegraphone records will be made of each and every transaction and filed away for reference. The telegraphone is destined to take the place largely of the present stenographer, and no business or professional man will think of writing his business letters, lectures, or sermons. The loud-speaking device, which is nearly ready for the market, reproduces sufficiently loud to fill a lecture hall, and makes it not only possible, but probable, that the telegraphone will play an important part in the entertainment field." The author incidentally mentions that on the occasion of their recent visit to Copenhagen, King Edward and Queen Alexandra manifested a deep interest in this invention. The *résumé* by Mr. Anderson, a barrister, of the United States patent laws is interesting from the historical standpoint. The author recalls the fact that the American patent system was based upon a statute of James I. The first patent law of the United States was enacted in 1790, and in 1836 a code was framed which forms the substance of the present system. The author calculates that something like 80 per cent. of American manufactures are the subject of patented inventions.

**Mercury Lamps in Practice.**—The Cooper Hewitt mercury lamps have recently been installed in the new building of the New York *Times*. This building consists of a large block 476ft. high, and all the machinery in it is to be electrically driven. The equipment of the building involves some 21 miles of conduit and 74 miles of wire,

Digitized by Google

and it is said that it will use over 1,000 units daily from the public mains. Apart from the motor equipment, on which we do not propose to touch, the interesting feature is that the lighting, both in the machine rooms and in the compositors' rooms, is carried out by means of the Cooper Hewitt mercury tubes. The colour of the lighting advertises the building from any point of the city. From the description of this installation which appears in the *Electrical World* of New York, we gather that in the press and stereotype rooms alone 26 of these lamps are used, and that these replace no less than 132 incandescent lamps and 14 arcs, although consuming only one-third of the current. These lamps light four large presses and a floor space of 17,000 square feet. The departments are 21ft. high. The diffused light obtained from these long tubes has entirely obviated the necessity of carrying wires all round the presses. In the whole building there are 42 lamps of the H-6 type, which are operated, two in series, off the 118-volt supply mains. The connections are shown in the



accompanying diagram, each pair of lamps taking 3½ amperes. In making out the original estimate for the lighting of the building, 15 kw. were required for the arcs and incandescent lamps. The Cooper Hewitt outfit actually takes 5·46 kw. Quite apart from this there has been a considerable saving in the wiring, owing to the smaller number of wiring points. The actual length of the tube used is 27¼in., but the light-giving portion is only 20¾in. The diameter of the tube is 1in. The lamps are placed within 15in. of the ceiling, which gives a good diffused light. Our contemporary states that in the type-setting department this is particularly advantageous, as there are no reflections to contend with.

**Electric Railway Progress.**—Dr. Louis Bell, in the *Electrical Review* of New York for Jan. 14, is responsible for a most interesting *résumé* on the developments in electric railways during the past year. We know of no one more able to fairly weigh up progress than Dr. Bell, and the following opinion from him as to alternating-current commutating motors is of great value. He says that "the greatest novelty of the year has been the steady heralding of a new era in which alternating current series motors shall reign magnificent. The preliminary tuning up and the premonitory blasts came last year. All this year we who wait have been hearing the fanfare echoing among the distant hills, but the head of the procession is not yet in sight. It has been announced repeatedly, but seems to be still marking time somewhere in the about-to-be To those who, like the writer, have been eagerly awaiting an alternating traction system, the delay is a keen disappointment. The conviction is growing in the engineering profession that Dr. Finzi's announcement forced the hands of the American manufacturers to a very embarrassing degree, and that while from a purely engineering standpoint some very admirable results have been reached, a policy has been inaugurated of sidestepping the issue whenever possible. There is little use speculating on the cause of this attitude, which may result from some trivial 'bugs' which still have to be exterminated, from sharp differences of opinion in the engineering staff, or merely from the desire to avoid the undeniable difficulties of badly-mixed production. The fact, however, remains that while alternating railway motors are apparently all ready for the market and are cordially recommended in cases suited to their use, such cases seem suddenly to have become most extraordinarily scarce. Why, we shall soon know, for the situation is too absurd to persist for any considerable length of time." Elsewhere in the *résumé* attention is drawn to the large locomotive for the New York Central system which has recently been tested. In this locomotive the motors are direct acting, there being no gearing between the motor armature and the axle. As the author points out, the escape from the usual dilemma between gearing and the difficulties of direct driving is very cleverly contrived. By making the truck frame part of the magnetic circuit and getting the necessary mechanical play in the pole-gaps, the weight carried dead upon the axles is actually brought below that necessary in a steam locomotive of equal power, with the advantage of the abolition of hammering due to reciprocating parts. This method also avoids the hammering due to the heavy un-spring-borne weight on the axles if the motor fields are directly supported on the same, as was the case in the original locomotives on the Central London Railway.

**Personal.**—The Society columns have been active lately with Mr. Marconi's name. Last week it was stated that he had become engaged to the Princess Giacinta Ruspoli, a daughter of one of the old Italian nobility. Later reports are to the effect that he is to contract an alliance with a compatriot of his mother. The lady named is the Hon Beatrice O'Brien, fifth daughter of the late Lord Inchiquin, and it is stated that the wedding will take place during the second week in March. The bride is of Royal descent, and the genealogists have been busy in tracing her ancestry back to Brian Boroihme, who reigned as King of Munster in the eleventh century. In 1543, however, his successor swore allegiance to Henry VIII., by whom he was created Earl of Thomond and Baron Inchiquin. Unfortunately, all these reports concerning Mr. Marconi's matrimonial affairs cannot be correct, but, as the *Express* is "authorised to announce" his betrothal to Miss O'Brien, we avail ourselves of this opportunity to tender our congratulations to the distinguished inventor.—Mr. E. Kilburn Scott, who, as already noted, is about to quit the Northampton Institute for Sydney University, delivers a valedictory address to his students in the institute's *Gazette*. He echoes the views of Prof. Perry and Mr. C. E. L. Brown that an engineer should also be something of an artist, and he also recommends the students to liberally avail themselves of the institute's fine library. He considers that they would even be justified in deleting one engineering class to attend the art department. Evidently Mr. Scott participates to some extent in the views lately expressed by Mr. Charles Hawksley, the past-president of the Institution of Civil Engineers, upon the æsthetic phase of engineering. Mr. Scott considers that engineers as a class are too "narrow," and that their conversation is too "shoppy," the result being that they are often exploited by some City financial man. The implied advice to look after the commercial as well as the technical side is doubtless good, though we scarcely think the modern engineer is so verdant as Mr. Scott suggests. Another point he emphasises is the importance of a good address, to attain which he tenders the excellent advice that students should join the Electrical Engineers Volunteer Corps. In conclusion, he alludes to Dr. Walmsley's aspiration that

Digitized by Google

the institute shall reach the highest rank, as represented by Charlottenburg, etc.; in fact, he says, "I have mistaken Dr. Walmsley's temper if the Northampton Institute does not attain very near to this ideal." As we are going to press we hear that Mr. H. M. Hobart has been appointed lecturer in electrical engineering design in succession to Mr. Scott. Mr. M. Holroyd Smith has been appointed chief assistant in the mechanical engineering department of the institute, in succession to Mr. W. E. Curnock, who has been appointed head of the mechanical engineering department of the Technical College, Huddersfield.

**Portable Wattmeter Calibrators.** — The Fort Wayne Electric Company have developed forms of a portable wattmeter calibrator, which they designate the "ringing" calibrator and the "registering" calibrator respectively. A description of these instruments, which are designed for use without removing the meters from service, appears in the *Western Electrician* of Chicago. In the ringing calibrator a standard wattmeter of suitable capacity, voltage, and frequency, but without registering mechanism, is mounted on the inside of a wooden carrying case. The case is provided with levelling screws, and a small spirit level is set into the base. A double-pole double-throw switch, by means of which the series coils of the standard can be connected either in multiple or in series for double or normal rated current, is also located in the case.

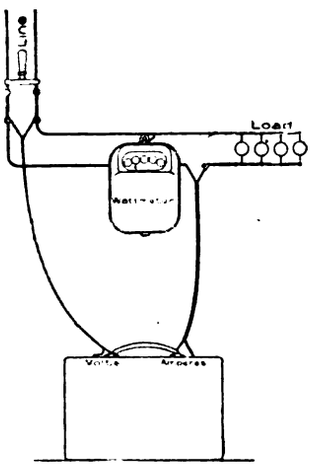


FIG. 1.

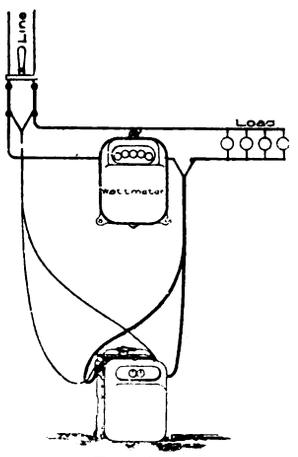

FIG. 2

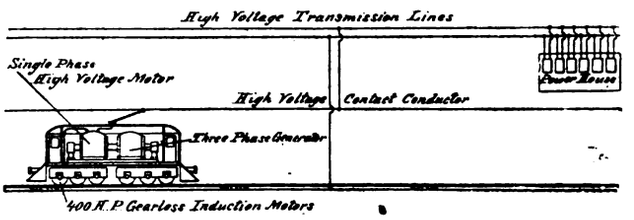
For normal calibration of five-ampere meters with switch down the coils are in series; for double this current the switch is thrown up. This prepares the calibrator for use with five and ten ampere meters by direct comparisons without a speed constant, the change in connections making no change in total ampere-turns or speed. The scope of the calibrator is magnified by using a speed constant of two for testing 15, 20, or 25 ampere meters, the series coils of the calibrator being connected in multiple by throwing the switch up. For comparing the speeds of the two meters a bell circuit is connected with the standard through a two-segment commutator on its armature shaft in place of the registering train. At every revolution of the standard armature the bell circuit is closed through a dry cell battery mounted on the left side of the case, thus ringing the bell. This bell circuit may be permanently opened when not in use by a two-point switch to prevent leakage of battery current, should the armature come to rest with the commutator closed. Fig. 1 represents a diagram of connections With a heavy load the meter should be adjusted in step with the standard by means of its permanent magnet, so that the spot on the meter-cup will always come to a certain point every time the standard bell rings for 5 or 10 ampere meters, or every other time for 15, 20, or 25 ampere meters. The registering calibrator has the usual registering train replaced by a double-reduction train, and has two dials instead of five. The dials register revolutions instead of kilowatts. Fig. 2 illustrates the connections, which are similar to those in the ringing calibrator. This device is simpler than the ringing calibrator, but its adaptability is more restricted.

**Alternating-Current Railway System.**—Mr. J. H. Hallberg contributes to the *Electrical World* of New York an interesting comparison between various alternating-current systems of working main-line railways. He lays down 12 different points which should be observed in the design of such systems, amongst which is one that the driving motors should not have commutators or brushes. In support of this he claims that the efficiency of the series commutator type of motor is low, and that this fault is exaggerated when it has to be geared to the driving axle. The author describes various systems which have been tried for driving locomotives by means of induction motors, and gives due credit to Continental pioneers in this field. He describes finally his own system, of which considerable detail is given. In it the high-voltage transmission line is connected directly to the contact conductor suspended over the track. The high-voltage transmission would be by single-phase currents at any voltage up to 15,000, with a frequency of about 25 cycles. In consequence of the connections there would be no sub-stations, but the locomotive would carry its own transforming apparatus. He proposes to use on the locomotive one large motor-generator. The motor would, of course, be of the single-phase synchronous or induction type, but later on Mr. Hallberg refers only to the synchronous type. This would drive mechanically a



three-phase generator. Owing to the absence of any commutating apparatus, the very high speed of 1,500 revolutions is suggested, which would enable a 2,500-h.p. set to be carried. The three-phase generator would be a four-pole machine provided with special connections, so that the polarity of one set of poles could be reversed. In this way it could be operated either as a 50 or a 25 cycle machine, which gives a speed variation on the motors of 50 per cent. In addition to the speed variation obtainable by frequency, the author proposes to regulate the field current on the three-phase generator so as to make a proportionate change in the current delivered to the driving motors. These would be of the standard three-phase induction type, wound for a frequency of 50 cycles and a voltage of 1,000. The author claims that the system has several advantages, amongst which is one that power could be returned to the line when the speed of the train had to be reduced. The approximate weight of a 3,000-h.p. locomotive of this type, including the motor-generator set, would not, it is stated, exceed 175 tons, and an overload up to as much as 4,000 h.p. is said to be possible. At the end of the article some figures of comparative efficiencies are given, which need to be carefully considered. With the use of induction motors there is a considerable economy in the introduction of pole-changing devices for speed regulation, and in consequence the Hallberg system has a higher over-all efficiency than some of the others described. It remains to be seen, however, whether the complications introduced by the pole-changing and by the high-speed motor-generator carried on the locomotive will be acceptable to railway engineers.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

(*Continued from page 79.*)

**Comparison of Bipolar and Multipolar Machines.**

The electromotive force existing between the positive and negative terminals will be that due to the number of active spirals existing between the brush and its neighbour (in this case three); and it is, therefore, independent of the number of pairs of poles and equal to the electromotive force generated by a bipolar machine with the same total number of spirals as this winding, and the same number of lines per pole, and running at the same number of revolutions per second as shown in Fig. 2; because in the two cases the product of spirals multiplied by lines cut per second will be the same. The arrangement of circuits of Fig. 1 as depicted in Fig. 3 may be compared with the corresponding diagram for Fig. 2 shown in Fig. 5. This comparison clearly demonstrates the fact that the two extra poles which Fig. 1 possesses above Fig. 2 simply results in placing two extra circuits in parallel with the original two, with the use of two extra brushes.

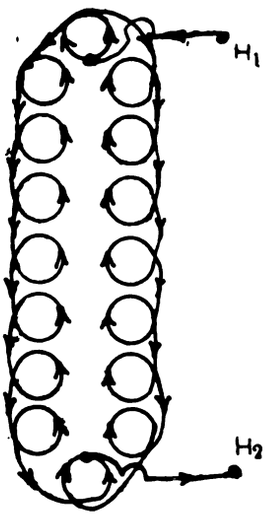

FIG. 5.

To contrast these two cases more clearly we may place them side by side as below:

| | Fig. 1. | Fig. 2. |
|---|---|---|
| Number of poles | 4 | 2 |
| Lines per pole | N | N |
| Total lines cut by one inductor per revolution | 4 N | 2 N |
| Total number of spirals on armature | 16 | 16 |
| Spirals per circuit | 4 | 8 |
| Electromotive force per circuit = product spirals per circuit × lines per revolution | 4 × 4 N | 8 × 2 N |
| Number of circuits in parallel in armature | 4 | 2 |
| Number of brushes | 4 | 2 |
| If the wire is the same in the two cases and its safe current is A amperes, then current from $T_1$, $T_2$ | 4 A | 2 A |
| Kilowatts output | 64 N A | 32 N A |

From the above analysis it is clear that the temperature rise in Fig. 1 would be very much higher than in Fig. 2, since both have the same cooling surface. It is, of course, assumed that the speed and pole-arc are the same in both cases.

It should be noticed that any one of the spirals in Figs. 1 and 2 might have been made up of several complete turns about the core, resulting in proportionately increased electromotive force; or, instead of having a total of sixteen spirals, there might have been any number, odd or even. The limiting conditions are (1) the space available on the armature, (2) the fact that the number of turns must be a multiple of the number of commutator sections, and (3) the number of turns per section consistent with sparkless commutation (a subject which we must omit). In any case, whatever number of spirals may be decided upon, the following general deductions remain unchanged:

(1) The winding requires as many brushes as poles.

(2) The winding is grouped by the connection of the brushes into as many parallel circuits as there are poles.

(3) The addition of another pair of poles with the same number of lines per pole simply adds another pair of circuits in parallel with the original number; thus the voltage given by the machine is not necessarily increased by the additional pair of poles, but the current which may be taken from it *with the same voltage drop due to armature resistance* is increased (approximately doubled).

(4) There may be any number of spirals on the armature, but this number must be equal to or a multiple of the number of commutator segments.

Such windings as these are designated by Parshall and Hobart *multiple-circuit windings because the minimum number of circuits possible is equal to the number of poles.*

**Cause of Re-entrancy.**

We have said that the winding in Fig. 1 is a *re-entrant* winding because it closes upon itself, and it is necessary now to enquire *why* it closes upon itself. A glance at the diagram shows that it is because the distance A B is an exact fraction of the armature circumference. In this particular case with sixteen spirals the distance A B (the pitch of the screw, we might call it) is one-sixteenth of the circumferential length of the armature. Hence: (5) A multiple-circuit winding will be re-entrant if the distance from spiral to spiral in the order of connection is $\frac{1}{S}$ of the total armature circumference, where S is the number of spirals.

**Pitch.**

Now we shall have occasion frequently to refer to this *distance* from spiral to spiral. There are two methods by which it may be expressed. The first is by speaking of it as a definite fraction of the armature circumference; thus, if a ring armature has sixteen spirals connected in series, we should call this distance one-sixteenth of the armature circumference. In this method of expressing the distance or *pitch* (for it clearly corresponds to the pitch of a screw) we shall speak of the *distance-pitch*, in order to obviate confusion between it and the second method. The latter consists in numbering the spirals (or inductors) in order around the armature, and then (since they are always regularly placed) speaking of the pitch as the difference between the number given to one spiral and that given to the one to which it is connected. This pitch we shall call the *number-pitch*, and it corresponds to that which Parshall and Hobart call, simply, *the pitch.*

Thus in Fig. 1 the distance-pitch is $\frac{1}{16}$, but the number-pitch is 1, because if we number the spirals

Digitized by Google

in order as they lie on the armature the difference between the number of any spiral and the one to which it is immediately connected is 1.

It is common to calculate the electromotive force given by a machine from the number of *conductors* which lie upon the outside of the armature—"The number of *active conductors* (or *inductors*)," as it is commonly called. It is also convenient to consider a spiral as being made up of that part which lies upon the outside of the armature and cuts the lines of the field, and another part which simply forms the connection between it and the active part of the next spiral. The part which lies upon the outside of the armature and cuts through the lines of the field is termed the *inductor*; and it will naturally possess, to complete the spiral, a connection at each end. Thus, a spiral becomes an inductor with two end connections, and is, therefore, for a ring armature, in shape like a distorted and inverted U sprung on to an iron core. In a ring winding all the wires which pass within the armature are *inactive—i.e.*, generate no electromotive force—so that the number of active inductors in a ring winding is equal to the number of spirals. If the axial length of the armature is great compared to its diameter, the waste of energy caused by the resistance of the long internal connection may be very large. Not only this, but a ring armature is slow to wind, for the wire must be passed by hand through the interior of the ring, which, in the case of high-voltage armatures having many hundreds of spirals, becomes a slow and tedious process. For these and other reasons drum windings have been very largely used.

**Drum Windings.**

The distinction between a drum winding and a ring winding simply lies in the fact that all the interior wires, such as those which pass through the armature at 1, 2, 3 in Fig. 1, are taken and placed on the outside of the core. In doing this, we must remember:

Firstly (since corresponding to each inductor there is one of these inner wires), the total number of inductors on the armature surface will become twice what it was in the original ring winding, so that no matter whether you wind the ring with an odd or even number of spirals, *the total number of inductors upon the surface of the corresponding drum armature must be an even number.*

Secondly, that in any spiral, such as that lying between A and B, the fact that the inner wire at 3 passes *back* through the armature, causes the current in 3 to be apparently opposite in direction to that carried by the inductor upon the surface at A. In Fig. 1, the current in the inductor, which lies on the outside of the ring at A, is supposed to come out of the plane of the paper towards the observer, and, therefore, in the wire which goes through the ring at 3 it must be passing from the observer back towards the plane of the paper, if it is to be collected at $G_1$. Therefore, if the wire represented by 3 is to be placed upon the outside of the armature, to become useful, and if it is to be directly connected to the inductor A, it must lie in a field of opposite polarity to that in which A lies. For, imagine for a moment the wire 3 placed anywhere upon the outside of the armature between A and $G_1$. It is obvious that 3, while forming the return for B, lies nearly always under the same pole as B, thereby counteracting any electromotive force generated by B, and rendering it practically non-inductive. An armature so connected would generate no average electromotive force whatever.

In Fig. 6 we have taken a six-pole machine with a ring winding of twelve spirals, and have numbered these spirals consecutively; then one of the inner wires marked C has been taken and placed upon the outside of the armature at $C^1$, where it becomes an inductor, lying under a south pole while inductor No. 1 lies under a north pole. But since the only condition determining the position of $C^1$ is that it shall lie under a south pole, we might have placed it just as well between

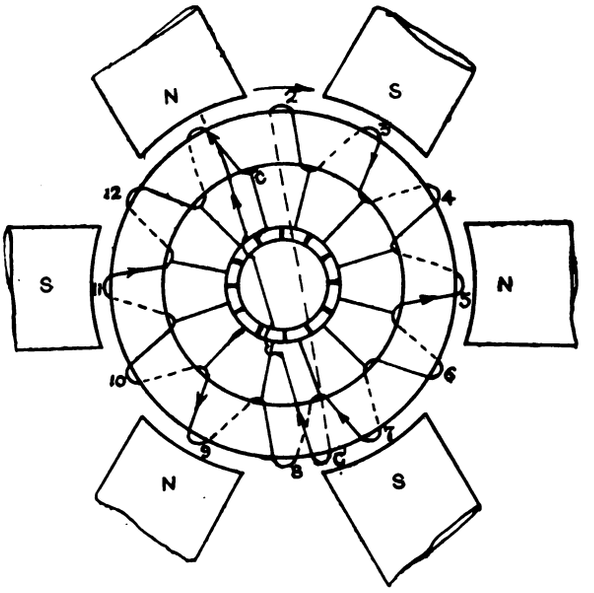

Fig. 6.

spirals 3 and 4 or 10 and 11. Obviously, it will be an advantage to place $C^1$ so that the connections between 1 and $C^1$ are as short as possible. If we remove every internal wire in the same way on to the outside of the armature, we shall get between each one of those outer inductors (which are numbered), and its neighbour, a second unnumbered inductor, such as $C^1$.

In Fig. 7 we have redrawn Fig. 6, placing in these extra unnumbered inductors. The rule for connecting

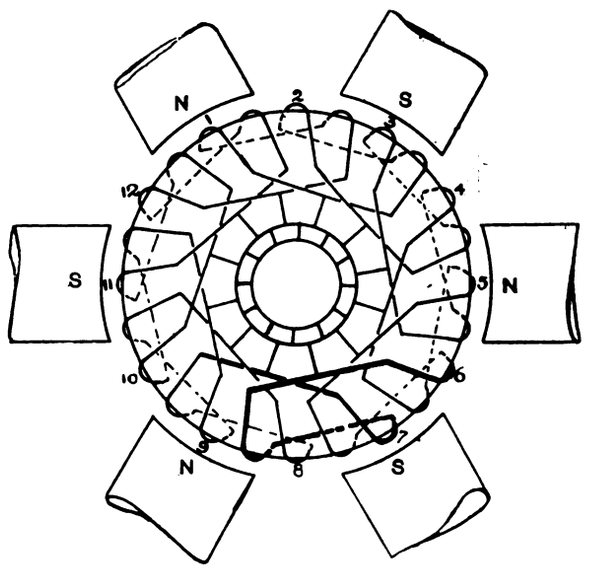

Fig. 7.

this winding is then simply this: Start from No. 1, go to an unnumbered inductor underneath the next pole, returning to No. 2, and so on. The winding may be completed as shown in the diagram. It will be noticed in Fig. 6 that we have cut through the connection C 2, but in doing so have left the connection from C to the commutator. It is clear that the connection might be made to the commutator from any part of the end connection 1 $C^1$ instead of leaving the

Digitized by Google

connection at C. The outcome of this is the arrangement of commutator connections seen in Fig. 7.

The dotted lines in Fig. 7 represent connections at that end of the armature remote from the commutator; and one element of the winding has been accentuated so as to show clearly the fact that inductors under poles of unlike polarity are regularly connected together.

Fig. 7 is in every way the exact counterpart of the ring winding depicted in Fig. 6, having the same number of commutator segments, of poles, and of spirals upon the armature, and yet *twice the number of active conductors* (or *inductors*). It will therefore need the same number of brushes upon the commutator, and with the same field at the same speed will yield twice the electromotive force generated by such a machine as Fig. 6. The number of brushes required for the winding in Fig. 6 is, from the rules already given for multiple-circuit windings, obviously six, and this will be the number required for Fig. 7. Their position upon the commutator may be determined exactly as was done before, and the circuits through the armature might again be represented by diagrams such as Fig. 3.

(*To be continued.*)

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

(*Continued from page 81.*)

In Fig. 15 another lay-out for the same design of switch is shown, but in this case the arrangement is compressed within narrower limits. The instrument and relay

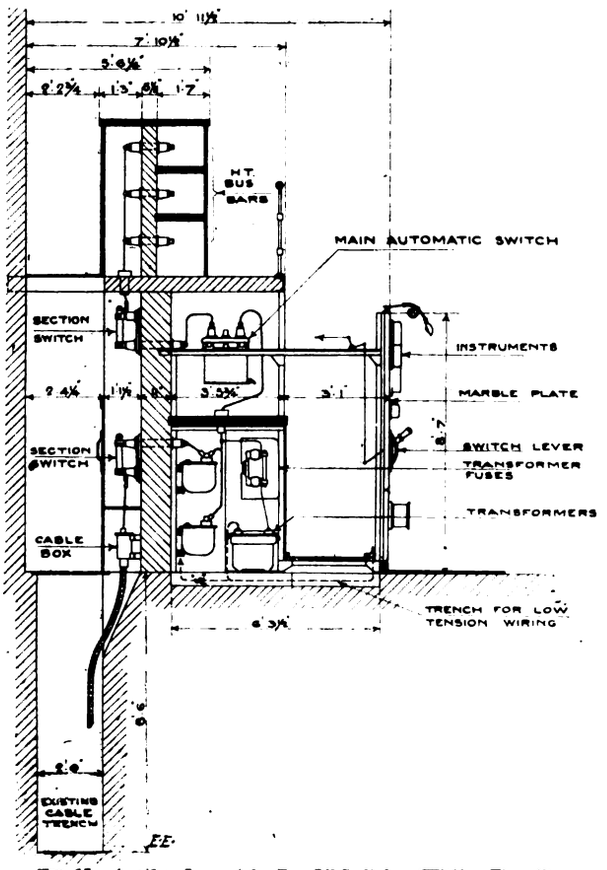

FIG. 15.—Another Lay-out for Box Oil Switches (Witting-Eborall).

transformers and oil switch are in the same position, the 'bus bars being, however, moved above the gear instead of below it. The connections to the bars can be more readily separated in this case, seeing that they pass *through* the wall to their respective bars instead of being on the same face with them. A design of this description is capable of controlling up to 1,000 kw. per panel, and is Witting-Eborall's standard for sub-station work. For generator and feeder circuits up to 1,500 kw. per panel the same firm make up an arrangement similar to that shown in Fig. 16.

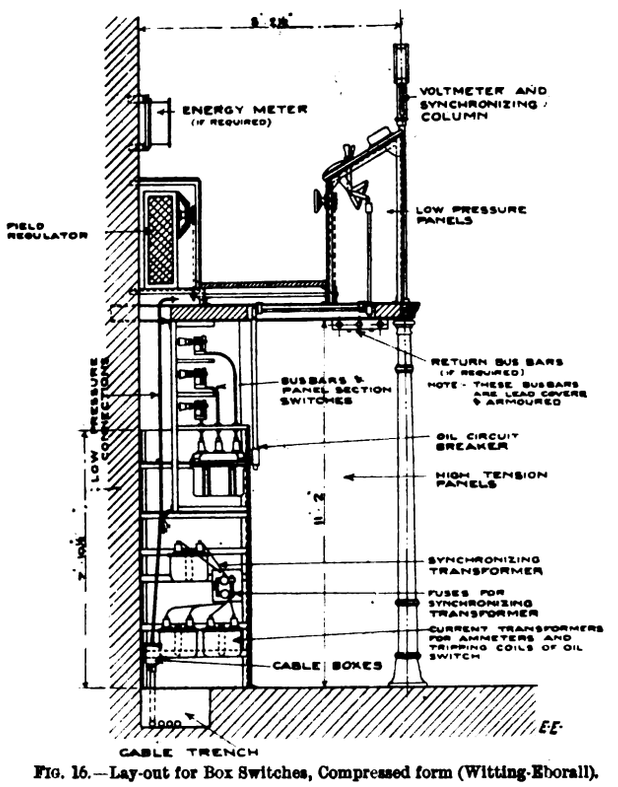

FIG. 16.—Lay-out for Box Switches, Compressed form (Witting-Eborall).

Here a complete tier is made of small transformers, oil switches, 'bus bars, and control board, the latter surmounting the whole. This gear is still more compressed, and might be employed where space is limited, as might be the case when such a gear was used to replace another type of board.

The method of operating the switch shown in Fig. 10 from a distance is illustrated in Fig. 17, but this needs little or no explanation. In Fig. 18 the cable connections are shown slung into position on insulators and clips. The

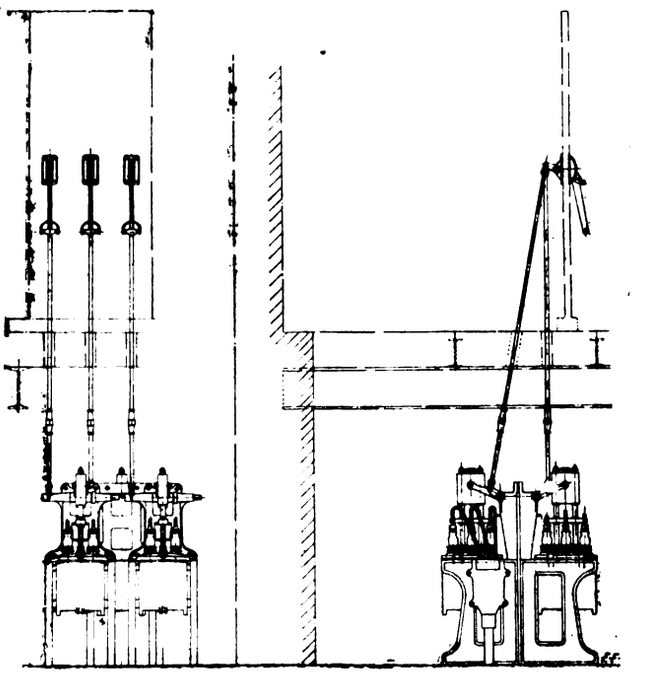

FIG. 17.—Lay-out for Oil Tank Switches (Dick-Kerr).

leads above the switches connect up to the different portions of the board, while the underground cables enter a dividing box, from which flexible tails are turned into the switch terminals. The method of thus slinging cables above the oil switches might appear risky should a fire

Digitized by Google

ensue, but as there would seem to be no possibility of this under even exceptional conditions the risk is somewhat exaggerated.

### Electrical Control.

The electrically-controlled switch hails from America; at any rate, in so far as the application of electricity to large power switches is concerned. Phenomenal developments in power plants, with accompanying rise in the transmission voltage, practically compelled the introduction of such a switch, and as since its employment it has been a complete success, its general adoption followed as a natural consequence. It is the generally recognised thing now to provide a separate direct-current source for operating such switches, which may in turn be classified into two distinct types—(1) the motor-operated switch, (2) the magnetically-operated switch. Opinion is fairly well divided as to the relative advantages of these, though among the more recent types there is a decided bias in favour of pull magnets.

It is not difficult to apply electromagnets to almost any switch, and reference to Fig. 19 will bear out this statement. Here an ordinary box oil switch is fitted with powerful pull magnets, in place of the handle, on the front of the marble panel behind which the switch is mounted. Two magnets provide for the "on and off" pulls respectively, the plungers being coupled by a chain passing over a pulley carrying a pin for the attachment of the operating lever. This latter is connected to the oil switch in a similar manner to that employed for hand operation. In this case the switch capacity is about 3,000 kw. at 15,000 volts, and the type is the product of the General Incandescent and Arc Light Company, New

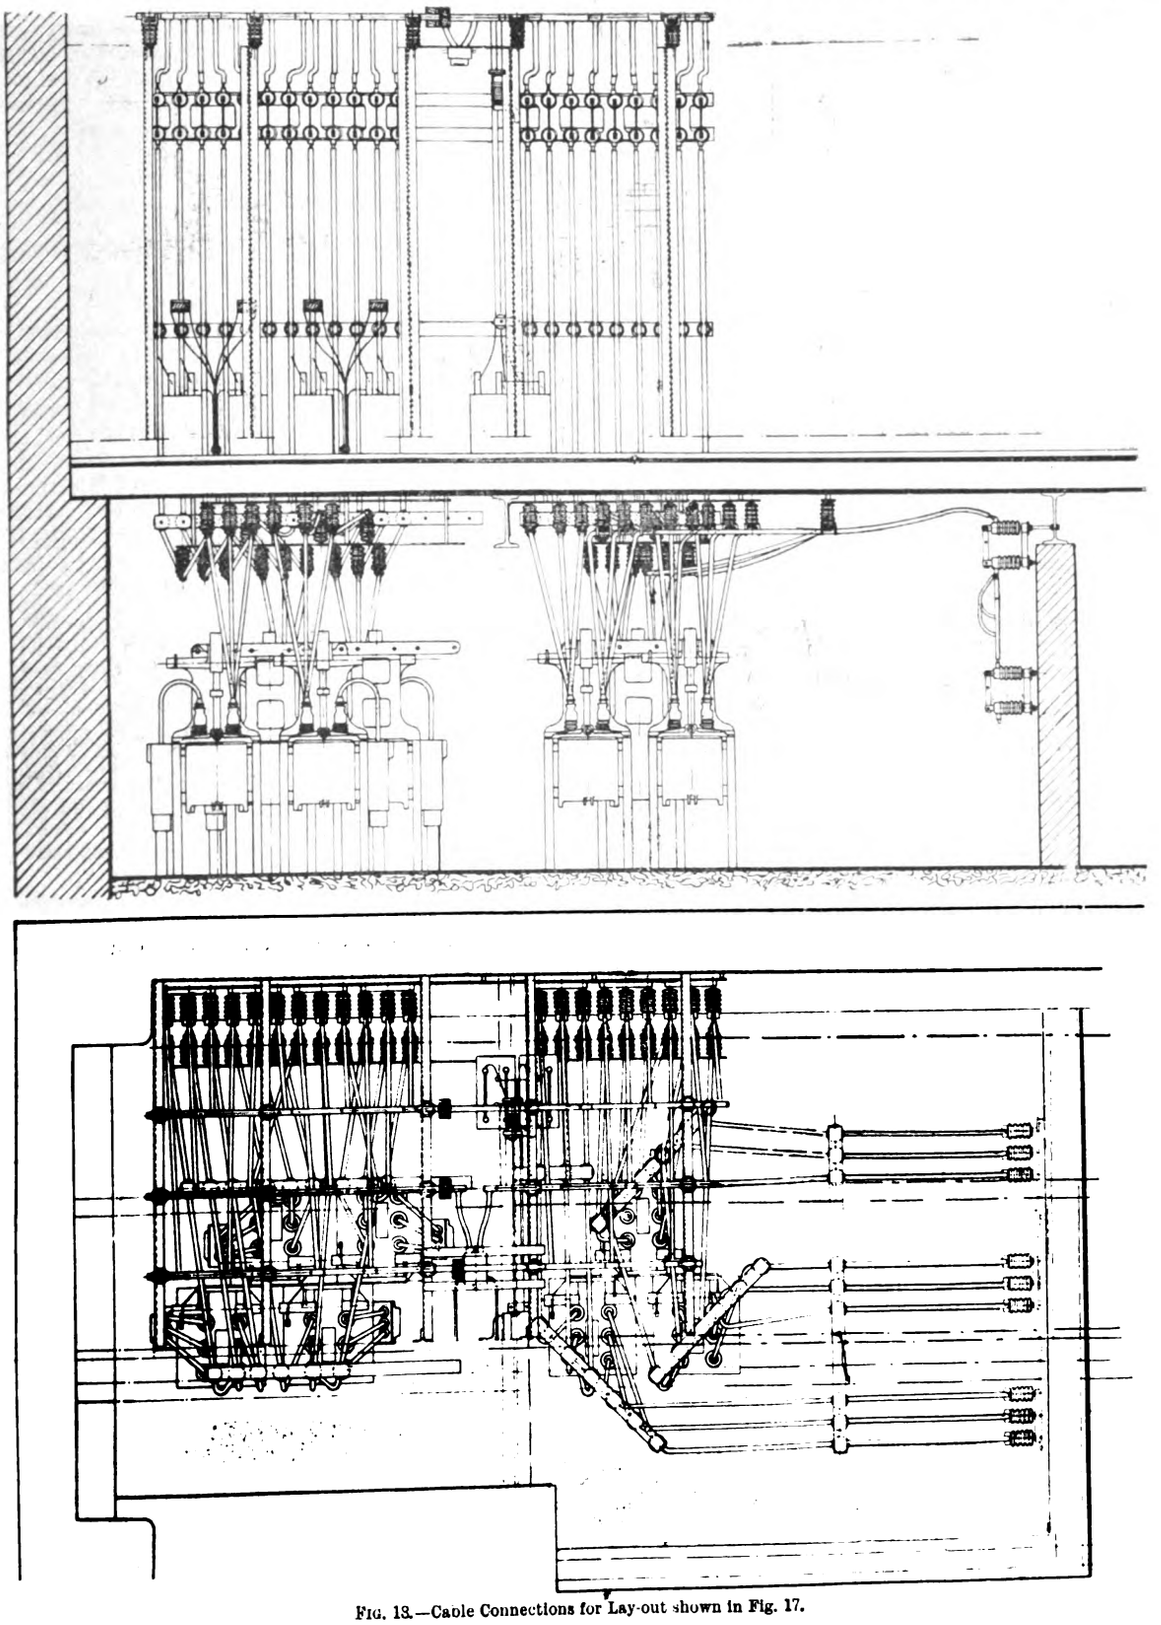

Fig. 18.—Cable Connections for Lay-out shown in Fig. 17.

Digitized by Google

York. The same firm manufacture a larger switch on similar operating lines, but with the switches proper mounted in separate compartments for mounting in brickwork. Fig. 20 shows front and side views of this type. The pull magnets are mounted above the switch cells on

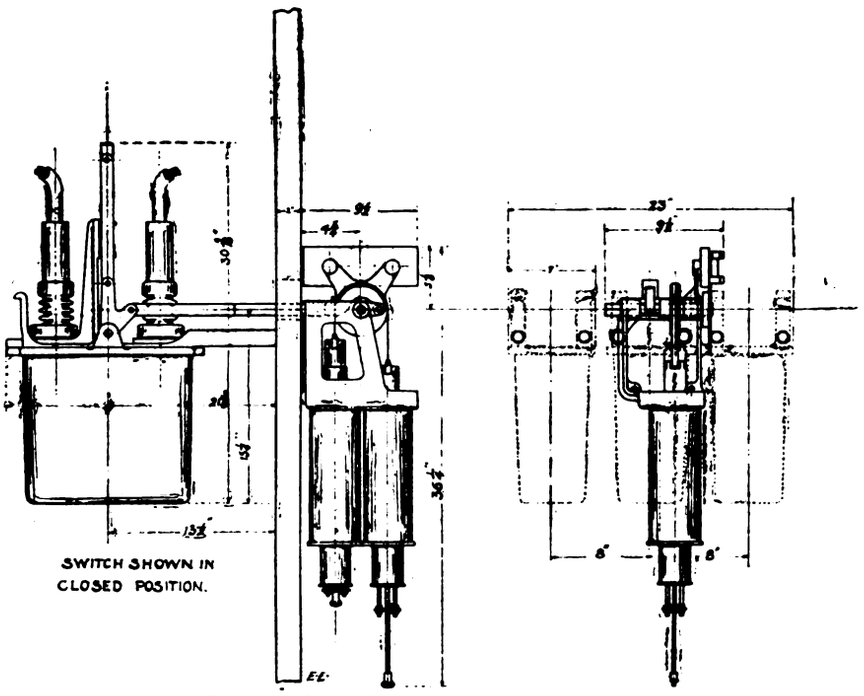

FIG. 19.—Electrically-Operated Box Switch (General Incandescent Co.).

a substantial cast-iron support, and serve to actuate the switch bar through suitable links and levers, in connection with which is a powerful spring. A small switch at the top of the device places either the "on" or the "off" magnet in circuit according to the position of the switch, though the actual closing of the magnet circuit is effected from

of the rods are fitted the bridging contacts to which the plungers are attached. There are two separate oil chambers, or tubes, per pole, each set in insulators in a small iron base, the top of the tubes being fitted with similar insulators for the passage of the switch rods. The cables enter below the switch at the two bottom contacts. Each set of oil-tubes is separated from its neighbour by brick, slate, or soapstone divisions, to confine any arcing which may arise to that particular panel. The upper and lower supports are distanced by tie-rods, which permit of adjustments in the throw being made. Switches of this character

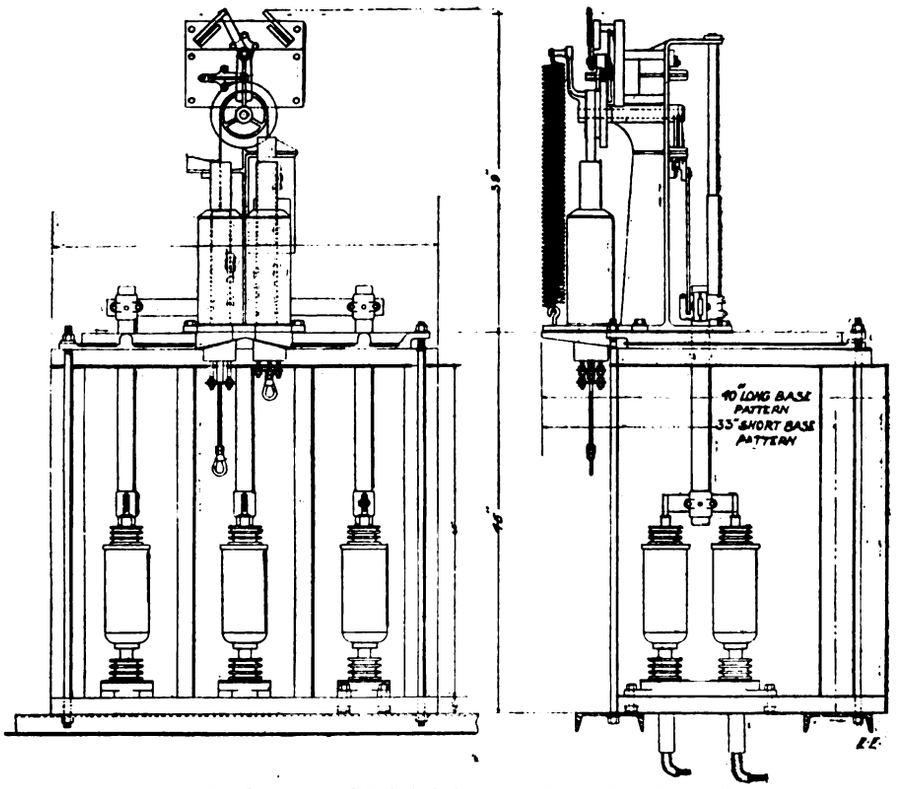

FIG. 20.—Magnet Pull Switch, large type (General Incandescent Co.

the distance control board. In closing the switch the spring is automatically wound up, and remains in a dead centre position, ready to be knocked over this centre by the pulling-off magnet directly this rises. A tripping coil to the right of the magnets in the side elevation (Fig. 20) also performs a similar function. A substantial casting couples the switch rods together above the main support, and at the other end will successfully cope with loads of 300 amperes at 15,000 volts, and they are extensively used in America on large power boards.

The foregoing type of switch requires brick compartments and special building arrangements for its fixing, and if a new switch were required at short notice, some little time would elapse before a new one could be inserted to replace

Digitized by Google

the damaged apparatus. To ensure the complete protection of the circuit, there are cases in which two switches are placed in series and one or other utilised under normal conditions to keep all parts in working order. Should one switch fail the other is immediately opened, reliance being placed on this to open the circuit. This practice is not now adopted, but when distance-controlled switches were first used this costly precaution was perhaps expedient. The brick chamber switch has now considerable vogue, and although there are types now constructed in which the complete circuit breaker is self-contained, requiring no brick partitions except for high pressures. The brick cell arrangement, however, is deemed advisable on grounds of absolute isolation.

*(To be continued.)*

## THE FAYET-CHAMONIX ELECTRIC RAILWAY.

BY DR. ALFRED GRADENWITZ.

The railway line connecting the above towns was included in the concession obtained in 1886 by the Paris-Lyons Mediterranean Railway Company for a normal-gauge line from Cluses to Chamonix The construction of the first section of this railway from Cluses to Fayet was not particularly difficult from an engineering point of view. There was, however, a difference of level between the two terminal stations of the final section of the line (Fayet-Chamonix) of about 1,500ft. The very high gradients involved therefore necessitated an alteration in the original concession. The company was accordingly authorised in 1893 to use a track of 1m. gauge, and to employ a rack rail wherever this should prove desirable. The scheme ultimately adopted was, however, such that these rack rails were dispensed with, and electric traction used throughout the section in question. The supply of the whole electric outfit of the railway was placed in the hands of the Alioth Electric Company, of Munchenstein, Switzerland.

The length of this section of railway is about 12 miles, and there are intermediate stations at Cheddes-Servoz, Les Houches, and Les Bassons. The line is to be continued later on as far as the Swiss frontier, and from thence on to Martigny. The track follows the valley of the River Arve, and in consequence of the frequent crossings a number of iron bridges and a large masonry viaduct have had to be constructed. There are also three tunnels, the longest one of which is 415ft. long. In consequence of the great difference in level between Chamonix and Fayet, two steep gradients occur on the line. On the first of these there is a 9 per cent. rise for a distance of 2,360 yards. The other has an inclination of 8 per cent., and is 1,520 yards long.

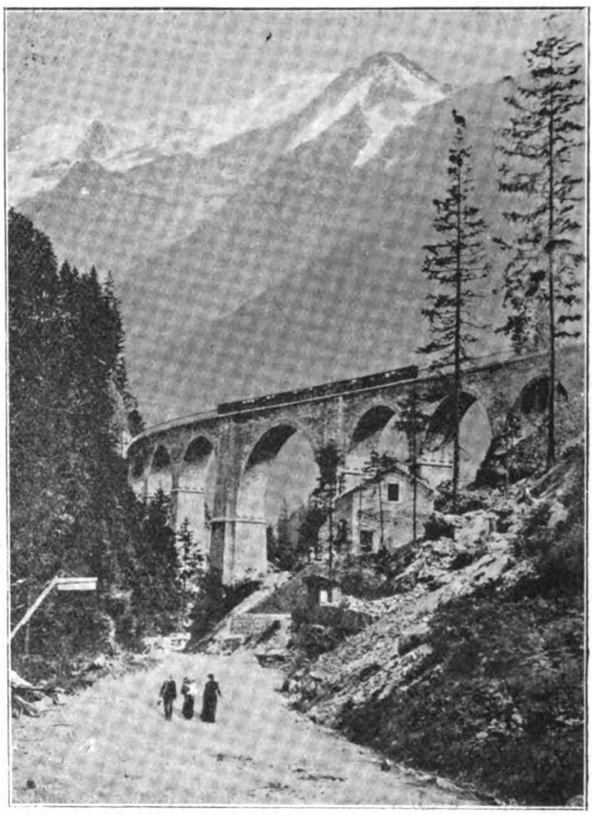

FIG. 1.—St. Marie Viaduct on the Fayet-Chamonix Electric Railway.

The remaining gradients nowhere exceed 3 per cent. The electrical energy required for operating the railway is obtained as 550-volt continuous current from two power stations, which have been erected at Servoz and Chavants respectively. In each case the water power of the River Arve is utilised. In the first central station there is a flow of about 425 cubic feet of water per second in the summer, with a head of 46ft. In winter the volume of the water available is about one-half. At the other power station at Chavants there is a head of

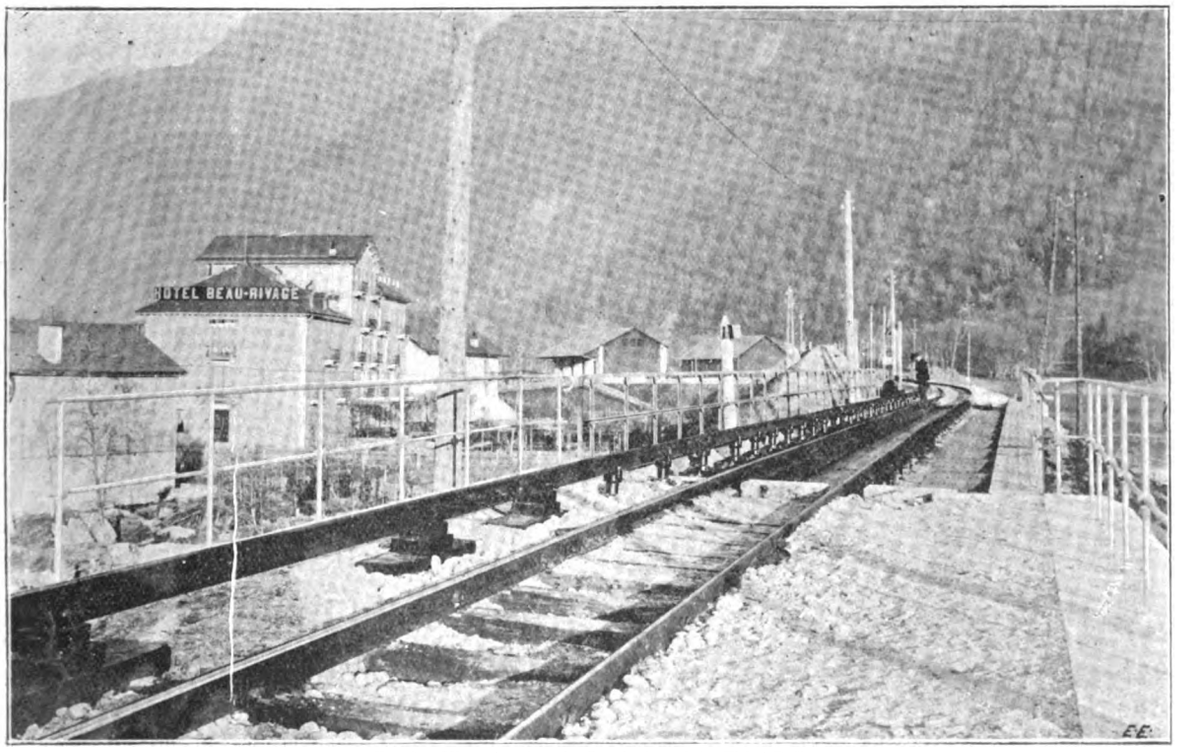

FIG. 2.—View showing the Insulation of the Third Rail.

Digitized by Google

310ft., and the volume of water is only slightly less. The machinery in each of these central stations includes four continuous-current dynamos, with an output of 200 kw. each, which are coupled by means of elastic couplings to horizontal turbines. There are also two 40-kw. dynamos, directly coupled to horizontal turbines, for exciting the above machines. In each station three generators and one exciter are used for normal working, while the other generator and exciter act as spares.

The permanent way is constructed with Vignoles rails, 39ft. long and weighing about 63lb. per yard run. The gauge, as mentioned above, is 1m. Energy is supplied to to the motors on the train by means of a third insulated rail placed alongside the track. This conductor rail is also of the Vignoles section of the same weight as the running rails. The centre line of this third rail is placed slightly over a metre distant from the centre of the track. This is about 23in. from the inner surface of the running rail. The upper surface of the third rail is placed 9in. above the upper surface of the running rails. The position of the third rail on one side or other of the track is varied, so that the trains are equipped with two collector shoes on each side of the motor carriages. This arrangement ensures that the connection with the third rail is always maintained in spite of interruptions in the same due to level crossings, or to changing the third rail from one side of the track to the other. At crossings the third rail may be interrupted for a distance of nearly 50ft. As shown in the illustration (Fig. 4), the third rail is protected by wood when passing stations, or at level crossings, where some 30ft. on each side of the crossing is guarded in this way. The whole of the permanent way is fenced in for further protection, and the crossing places have been reduced to a minimum. The third rail is insulated by wood blocks which have been saturated in paraffin; these insulating blocks are supported on wood bearers, which are secured on to the ends of two consecutive sleepers. This insulation is said to have given satisfaction, the leakage current

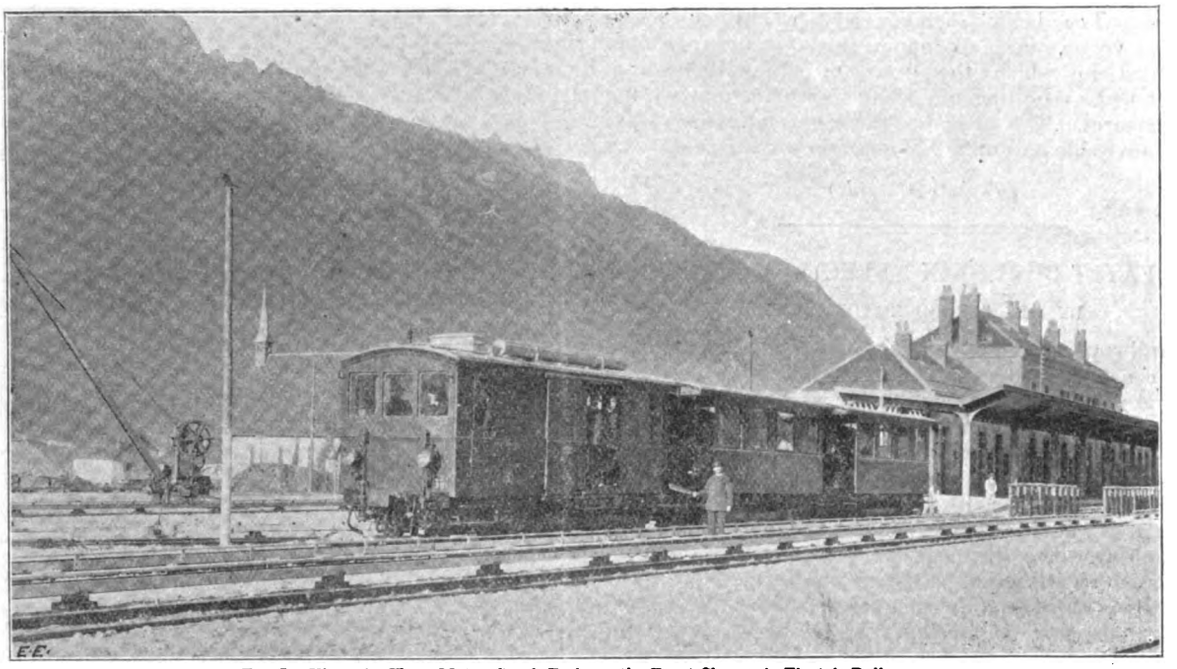

FIG. 3.—View of a Three-Motor Coach Train on the Fayet-Chamonix Electric Railway.

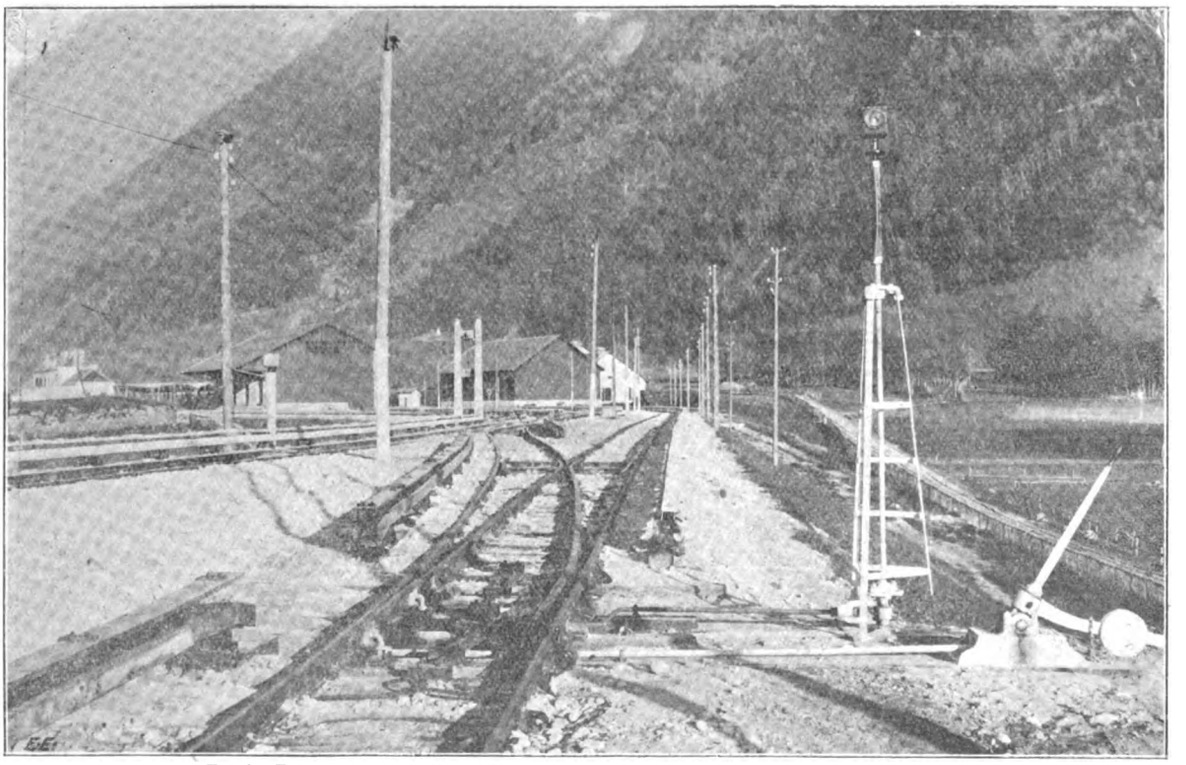

FIG. 4.—Entrance to the Station of Chamonix, showing the method of Guarding the Third Rail.

Digitized by Google

per mile being less than 1½ amperes. It is a curious fact that this leakage should actually decrease during rain or snow. The reason for this is that the rain which falls in the Chamonix district is practically free from all chemical impurities, and thus possesses almost as low a conductivity as distilled water. This rain removes dust from the supports of the third rail, and hence increases the insulation resistance. On the heavy gradients a central rail of the same type is placed between the running rails with its upper surface 2½in. above the same. This is used in braking when the trains are descending the grades, being acted upon by slipper brakes.

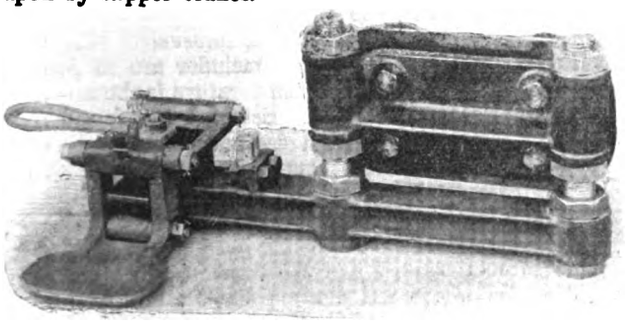

FIG. 5.—The Current Collector.

The rolling-stock was supplied by the Société Nouvelle des Etablissements de l'Horme et de la Buire of Lyons, but the Alioth Company supplied all the electrical equipment. The first order was for 80 motorcars, and further orders have recently been placed. There are also a number of trailers, each seating 40 passengers. The ordinary train will consist of between five and seven motorcars and a few trailers. It is quite possible, however, for the motorcars to be run singly, and they are in that case operated by one man. The control of the train is effected on a system due to the chief engineer of the Paris-Lyon Mediterranean Company (Mr. Auvert). The front car of every train is equipped with a master controller worked with compressed air. By means of two conductors the controllers on each of the motorcars are then controlled by means of compressed air. The actual movement of the controllers is effected by a rack working a toothed wheel on the controller shaft. Eighteen of these leading carriages are provided with air-compressor and master controllers. There are 36 passenger motorcars equipped with first and second class accommodation, which weigh when empty 19½ tons. Besides these there are 28 motorcars for goods traffic, some of which are completely closed and other half open. These goods cars are designed for the maximum load of 10 tons. Both the slipper brakes acting on the fourth rail on the heavy grades and the ordinary brakes on the running wheel are actuated by compressed air. The contact shoes are of the Alioth type, made of cast steel, as illustrated in Fig. 5, and designed so that protecting wood casings can be placed over the third rail in the stations. At points where the third rail is discontinued the last section is given a gradual slope, so as to prevent mechanical shock when a contact shoe approaches. Both the slipper brake and the brakes on the wheels can be operated by hand if need be. The trucks, of

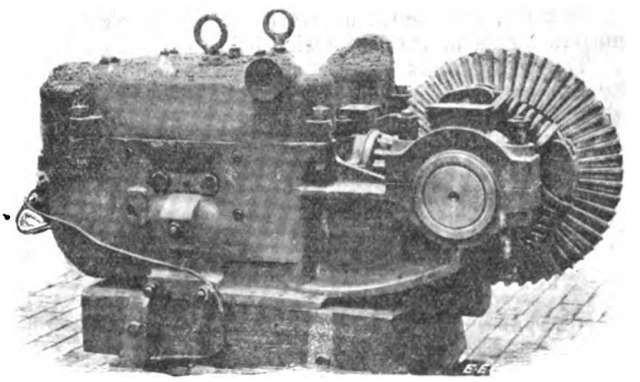

FIG. 6.—General View of Motor and Gearing, showing Spring Drive.

which there are two for each motorcar, have each two axles, one of which is motor driven. The design of the motors was rendered somewhat difficult by the gauge, which is only 1m., and by the fact that the two motors in each carriage had to be capable of taking the same up the long grades of 8 and 9 per cent. The problem was solved by placing the axles of the motor at right angles to the axle of the carriage. The motor transmits the power to the carriage axle by means of bevel gearing with a ratio of 1 to 4. The pinion on the motor shaft gears into the bevelled wheel, which is carried on a sleeve on the carriage axle and drives the same through springs, as shown in the illustration (Fig. 6). The gearing is completely enclosed, so that lubrication can be more easily effected. The use of the elastic coupling between the motor and the carriage axle is advantageous, as it reduces shock at the moment of starting. It was felt, however, that there was some danger in the adoption of the bevelled gearing. It has been found by experience, however, that the wear and tear in this gearing is very small, which is largely due to the same having been carefully cut by special machinery. The motors used are of the four-pole type, the magnets and casing being of cast steel. They are formed in two halves, which when bolted together completely enclose all the collecting gear. The field coils are wound on

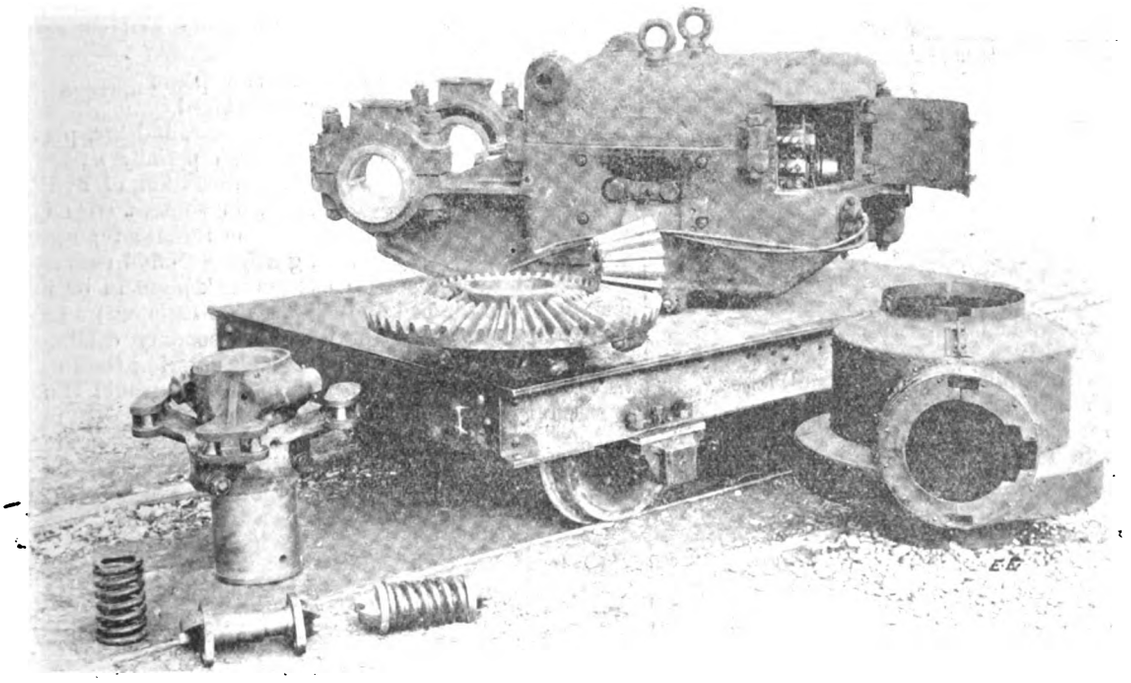

FIG. 7.—Motor Parts Dismantled, showing the Driving Sleeve, Springs, Gear Wheels, etc.

Digitized by Google

metallic bobbins, which are easily replaceable. Copper strip 1mm. thick and 48mm. wide is used for the field magnet. The armature is of the toothed-core drum type, with 113 commutator sections. The motor can give an effective output of 65 h.p. for two hours at 550 volts with a speed of 275 revolutions per minute without any part of the magnets or armature rising more than 60deg. C. above the surrounding temperature. If, on the other hand, the motors have at the start a temperature of 40deg. C., they can be worked at 120 h.p. for 10 minutes without the temperature rise being such as to damage any part of the insulation. The brushes have a fixed lead for either direction of rotation, and the motors work without sparking at any output. This allows the trains being braked electrically. The two motors are always connected in parallel, and by reversing the direction of the current in the armature the trains can be quickly slowed up, even on the 9 per cent. grade. The fact that the wheels continue to rotate at a very low speed but are not locked gives a much better result than other systems of braking, which are apt to lock the wheels, causing the train to slide with a considerable diminution of adherence.

As regards the regulation of the motors, all the cars in a train are operated simultaneously by the driver in the front van by means of the compressed-air relays. The controllers of the cars have, therefore, to be made as simple as possible. On the other hand, on account of the considerable grades, there was a danger of slipping taking place if the motors were started in series. An extremely simple controller was, therefore, adopted with five forward and five backward positions, which allowed only for the coupling of the motors in parallel. The first four speeds in either direction are

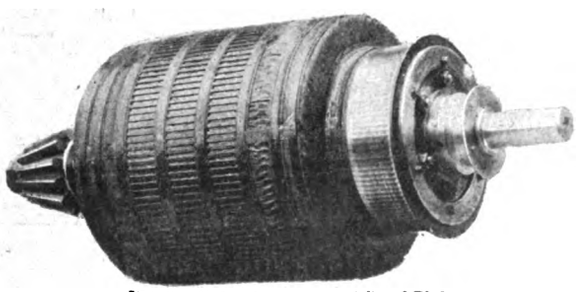

Fig. 5.—Motor Armature and Bevel Pinion.

obtained by inserting suitable resistances in the motor circuit. The fifth speed is obtained by shunting the series winding on the field magnets. The controller thus becomes a very simple one, which, in the event of a single car being required, can be worked by hand.

The regulating resistances are of a very simple type, consisting of high-resistance ribbons wound spirally with asbestos in between the adjacent layers. Each car is lighted by means of 10 incandescent lamps, connected in two parallel circuits with five lamps in series. The signal lamps are, however, of the oil type, so that the signalling may be independent of the continuity of the electric supply. In order to maintain a uniform lighting in the carriages, in spite of variation in the voltage on the line, an automatic regulator is used in the lamp circuit, which has been patented by the Alioth Company. The apparatus and equipment is so designed that the full candle-power can be obtained from the lamps on the lowest voltage likely to be met with when ascending the heavy grades. A voltage regulator then operates relays which automatically switch into circuit one or more resistances as the line voltage rises, so that the voltage across the terminals of the lamps remains approximately constant. The voltage regulator which actuates these relays is constructed on the moving-coil principle. The working of the apparatus is said to be very satisfactory, and such a device is needed on long lines where good voltage regulation cannot be economically obtained. The heating of the cars is also carried out electrically by means of electric radiators, which are controlled by means of a three-way switch. This gives three different temperatures on the radiator, so that the heating of the cars can be easily regulated.

My thanks are due to the Alioth Company for the photograph reproduced herewith, and for the information from which the above article was prepared.

## REFUSE DESTRUCTORS.

The following is a report on tests carried out on Jan. 13 and 14, 1903, by the Manchester Steam Users' Association, under the supervision of Mr. C. E. Stromeyer, their chief engineer, at the destructor works, Nelson.

The destructor was designed and erected by Messrs. Meldrum Bros., Limited, of the Engineering Works, Timperley, near Manchester, and is of their front-feed regenerative Simplex type. It has one continuous grate, 20ft. by 5ft., in a furnace chamber 22ft. by 6ft., having four separated and closed ashpits separately supplied with hot air under pressure. There are four feeding and clinkering doors through which the refuse is charged and the clinker withdrawn in rotation at regular intervals. When any one fire is being clinkered the remainder are in full work, so that a comparatively even temperature is obtained, never falling below incandescence. Between the furnace proper and the boiler is placed a secondary combustion chamber, where the maximum temperature is obtained, and where the oxidation of the gases is completed and the major proportion of the dust deposited.

The boiler is of the Lancashire type, 30ft. by 8ft., for a working pressure of 150lb., and with the usual modern setting. The combustion gases, after leaving the boiler, pass through a regenerator, where the air supplied to the ashpits under pressure by means of steam jet blowers is preheated to about 350deg. F. The gases entered the chimney at an average temperature of 645deg. F., which would easily allow of the addition of an economiser, by means of which the evaporation from and at 212deg. F. would be brought up to fully 2lb. per pound of refuse.

THE MANCHESTER STEAM USERS' ASSOCIATION.

Office, 9, Mount-street, Manchester.
July 23, 1903.

Messrs. Meldrum Bros., Limited, Timperley.

Gentlemen,—In accordance with your instructions we carried out a two days' economic test on the refuse destructor and boiler at the Nelson Corporation destructor works, Nelson. A special feature of this plant is that the air which is blown into the furnaces is hot, and the furnace temperature is naturally higher than if cold air had been used, and the chance of noxious vapours passing away unconsumed is thus materially diminished.

Steam jets are used under the firebars, and are, perhaps, an essential feature of the system, especially as regards keeping the firebars cool, but the liberation of hydrogen which takes place when steam is in contact with incandescent fuel, must tend to lower the furnace temperature somewhat. It was, therefore, gratfying to find that recombination of hydrogen with oxygen took place in or immediately above the bed of fuel, and that little or no air had to be admitted above the fires for secondary combustion, the damper being closed and little air entering the furnaces when the floors were open. The refuse would thus be exposed to the maximum temperature attainable in the furnace instead of being first partly volatilised and then consumed as gas.

Doubtless, when charging a furnace, of which there were four, the top layer of fuel will for a time give off gases, but the brick combustion chamber having a very large capacity, and being at a very high temperature, caused these gases to be at once consumed. The estimated mean temperature on the two days were 2,634deg. and 3,326deg. F., and the nickel, melting at 2,640deg. F., was fused when held in the flame.

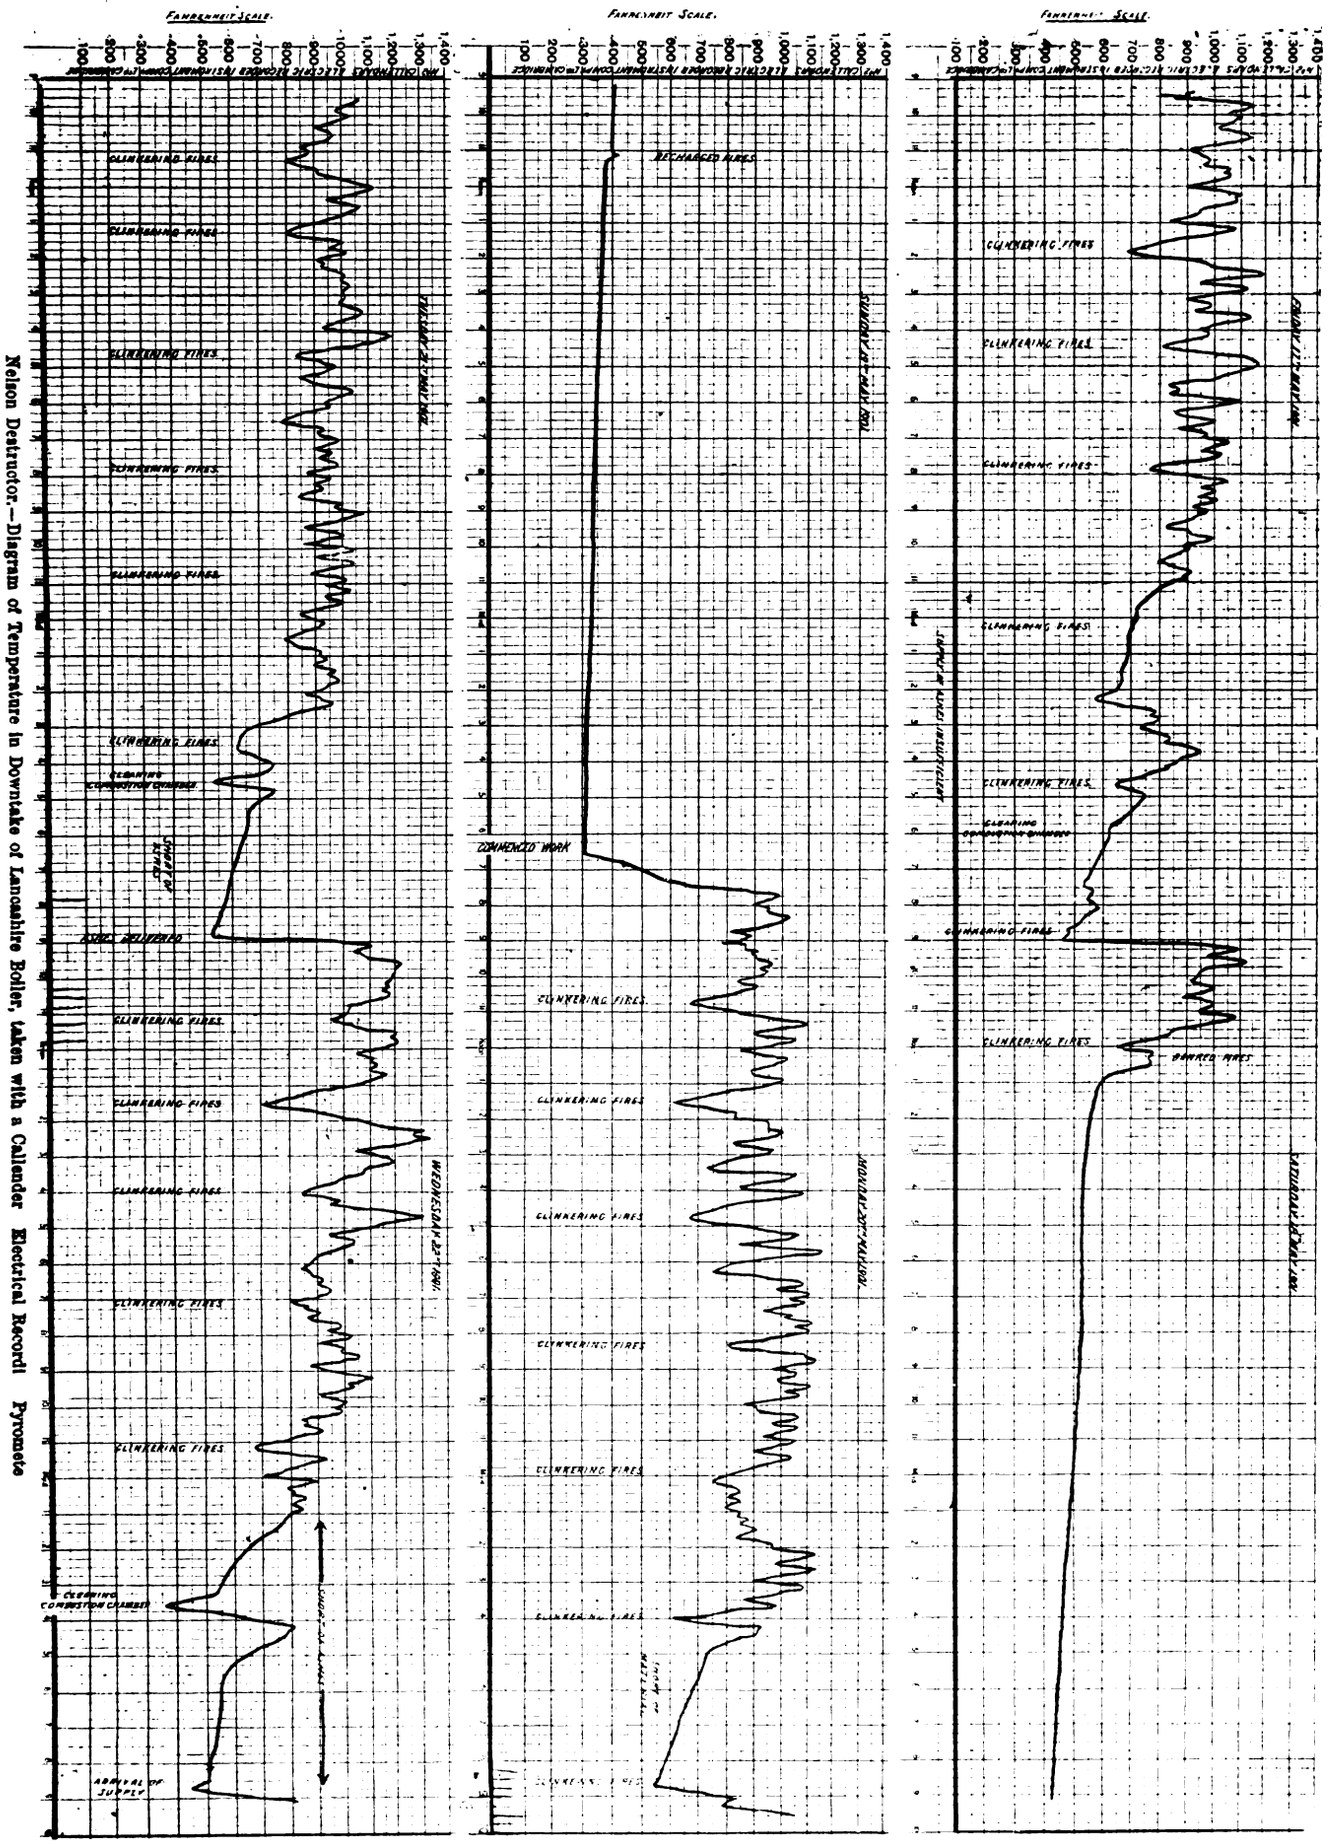
A costly electric platinum wire resistance pyrometer was lowered into the end of the combustion chamber where the hot gases entered the boiler, and was destroyed.

The refuse consumed at Nelson was taken from exposed ashpits, and consisted principally of cinders and kitchen refuse; offal from the slaughter-houses was also burnt in this destructor, but in view of the nature of this fuel being totally different from that burnt during the rest of the time, it was considered advisable not to complicate matters by burning this offal during the test. It may here be mentioned that refuse of this nature is shot into the extreme end of the combustion chamber, so that noxious

Digitized by Google

gases which would be generated have to pass over four furnaces, whose fuel is on such occasions purposely well burnt through.

the next lot was tipped. The two days' trial, therefore, consisted of a series of six short ones, which could be compared amongst themselves. The ashes drawn from the



Nelson Destructor.—Diagram of Temperature in Downtake of Lancashire Boiler, taken with a Callender Electrical Recordi Pyrometer

The trials were carried out on Tuesday and Wednesday, Jan. 13 and 14, 1903. The refuse was weighed on entering the premises. A sufficient quantity to last for nearly three hours' run was tipped into the bin, and was burnt up before furnaces were placed in the yard to cool, and were subsequently weighed, sampled, and analysed.

The feed water was carefully measured by means of three tanks. The temperatures were taken of the feed

Digitized by Google

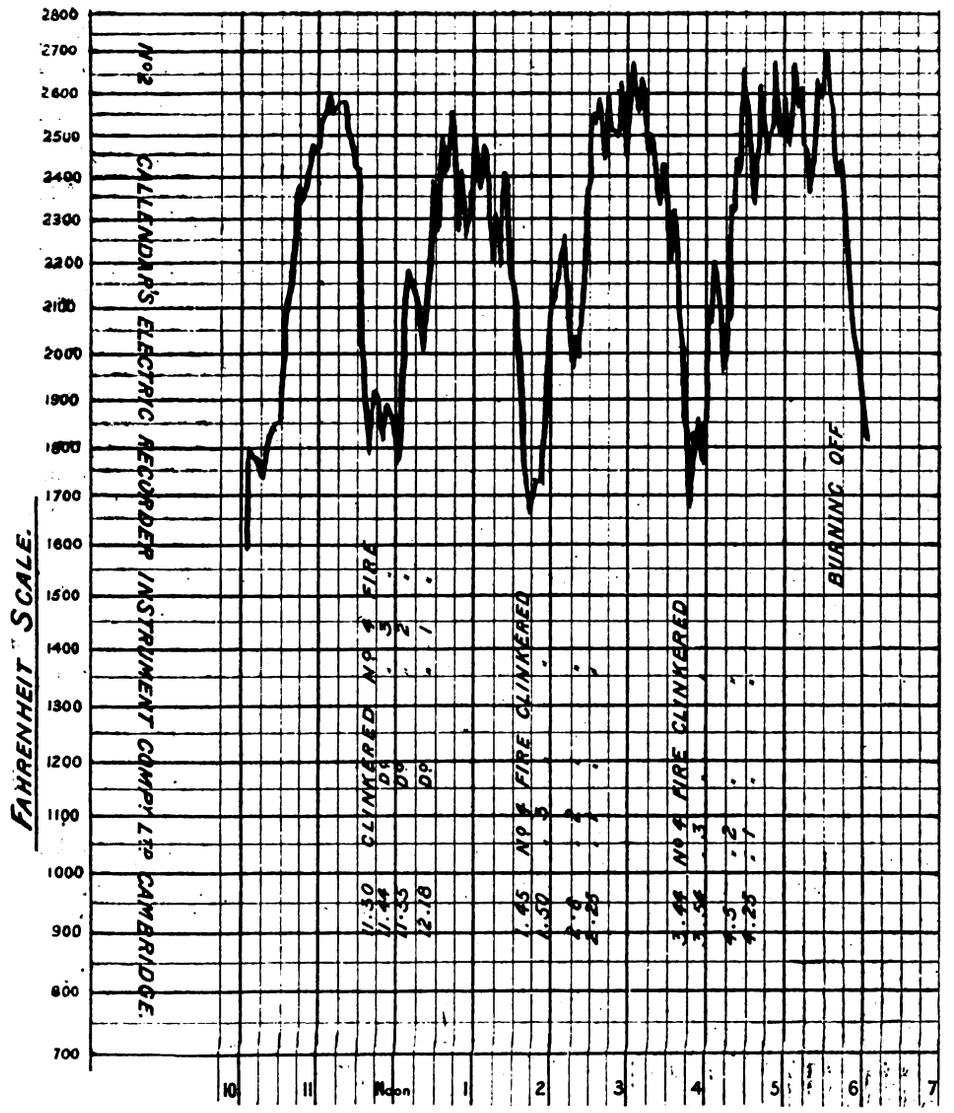
water, of the air (dry and wet bulb), of waste gases in the side flues before entering the air heater and after leaving it; also of the air supply to the furnaces both before and after heating.

Continuous gas samples were collected and analysed at once in an Orsat apparatus, and continuous gas samples were taken from the same suction pipe and passed through calcium chloride and potash tubes to determine both the moisture and the carbonic acid. This is an important and distinctive feature of this trial.

The Callender electric pyrometer, referred to previously as having been destroyed on the second day in the combustion chamber, was used for giving a record of the downtake temperature during the first day's trial.

One of the mercury nitrogen pyrometers in the end flues burst on account of the temperature exceeding 1,000deg. F. by making continuous and complete gas analysis, including the moisture in the waste gases. With the help of the information thus obtained, it was possible to calculate the chemical composition of the fuel (it contained on an average 31·4 per cent. carbon and 0·5 per cent. hydrogen), its calorific value (4 6 evaporative units), and the weight of waste products per pound of refuse (5·61b.) were then calculated. These additional details enable one to strike a balance-sheet of the heat expenditure.

It will be seen that the heat utilised in the production of steam (exclusive of the blowers) amounted to 36 per cent., which must be considered a high duty when it is seen that the carbon and the heat in the ashes account for a loss of 20 per cent. With ordinary fuel containing only a few per cent. of mineral matter this loss would have been only about 2 to 3 per cent., and then the efficiency would



Nelson Destructor.—Eight Hours' Test.—Diagram of Temperature in Combustion Chamber, taken with a Callender's Electrical Recording Pyrometer.

It was replaced by a Thalpotassimeter, a pyrometer in which the temperature in indicated by the pressure of mercury vapour.

High-temperature thermometers, either mercurial or electric, do not give reliable results, the zero point shifting very considerably, and in this trial there is a distinct disagreement between the readings of the temperature of the waste gases and of the incoming air. Probably the most correct readings are those of the thermometer in the main flue leading to the chimney, and these have been utilised in the compilation of the balance-sheet.

Table I. gives a brief summary of those details of the two days' trial, which is usually the only information that has been obtained from destructor trials; and it will be seen that the evaporation from and at 212deg.F. is 1·7881b. of water per pound of refuse.

Table II. contains details which were only obtainable have been 45 per cent. The heat carried up the chimney amounts to an average of 19·3 per cent., which is reasonably low. It would, of course, have been much lower if the refuse had contained less moisture—32·7 per cent.

There is a considerable difference between the estimated radiations on the two days. It amounts to 9·4 per cent. on Tuesday and 30·6 per cent. on Wednesday. The estimated flame temperature was certainly hotter on the second day, and increased radiation may account for part of the difference. Possibly this difference may be due to unavoidable errors of observation. Thus, if the weight of steam blown under the firebars was more or less than stated, or, if the fine dust, which is taken at 5 per cent. of the refuse, differed on the two days, or if the moisture in the waste gases, which was on an average 0·75 on Tuesday and 0·55 on Wednesday, varied considerably on each day, the mean values deduced from the average gas analysis may not be

the true mean, and comparatively slight alterations in all these quantities could easily affect the balance-sheet by a few per cent.

The mean radiation is 20 per cent., or 5,959 evaporative units per hour. The boiler and air heater expose a surface of about 1,300 square feet, and would radiate about 350 evaporative units, and the combustion chamber with a surface of about 1 300ft. and an internal temperature approaching 3,000deg. F., may be credited with a radiation of 2,500 evaporative units. This leaves 2,200 evaporative units unaccounted for, or about 9 per cent. In view of the difficulties of making these various determinations this quantity must be considered reasonably small. If we deduct it from the total, then the efficiency of the installation is raised from 35 per cent. to 40 per cent., which is just under the value obtained on the first day, and must be considered to be an exceedingly good result.—Yours faithfully,

(Signed) C. E. STROMEYER, Chief Engineer.

## PERSONAL.

Mr. M. H. Volk, who has just resigned his position as works engineer to the Brighton Corporation tramways department, is about to take up an appointment as engineer and manager to the Brighton Beach electric railway. Last week, the tramways engineer and general manager, Mr. T. B. Holliday, presented Mr. Volk with a case of drawing instruments and a book on railway working, and a walking stick on behalf of the office and works staffs.

The Huddersfield Corporation have decided to increase the salary of Mr. J. C. Whiteley, chief assistant in the tramways department, from £150 to £160 per year.

The Electric Lighting Committee of the Wakefield City Council have decided to recommend the appointment of Mr. Harry Anderton Neville, first assistant electrical engineer at the Corporation works, as electrical engineer from April 1, at a commencing salary of £300 per annum, rising by annual increments of £25 to £400 per annum.

## APPOINTMENTS VACANT.

**Assistant Electrical Engineer**, West Bromwich. Commencing salary, £120 per annum. Applications to the Borough Electrical Engineer and Manager by Feb. 4. See advertisement.

**Clerks**, St. Marylebone Borough Council. Ledger clerk, at a commencing salary of £100 per annum, and a junior clerk, at a commencing salary of £50 per annum. Applications by Feb. 4. See advertisement.

**Draughtsman**, South Shields electricity works. Salary, £3 per week.

**Construction Superintendent**, Leith Corporation tramways. Salary, £3 per week. Applications by Feb. 1.

**St. James and Pall Mall Electric Light Company.**—The directors recommend a dividend for the half-year ending Dec. 31 of 7s. 6d., together with a bonus of 2s. per share, on the ordinary shares, making, with the interim dividend paid on Aug. 1 last, a total distribution of 14½ per cent. for the year.

## ALTERNATING-CURRENT TRACTION.

The use of the alternate-current induction motor for traction purposes is by no means new. It was first tried on a commercial scale by Mr. C E L. Brown, who equipped in Switzerland first tramways and later some full-gauge railways on the three-phase system. The lines so equipped have done and are still doing good work, but there are certain objections to the three-phase induction motor as applied to traction which limit the extension of the system in its simplest form. The first of these is that the maximum speed of the train propelled by the ordinary three-phase induction motor is fixed once and for all by the frequency of the supply current. This is so much the case that it is a distinct advantage on the heavy grades of railways running through mountainous districts. When descending these grades the three phase motors act as generators, and return energy to the line immediately their speed exceeds by a few per cent. that corresponding to synchronism with the alternators in the generating station. Coupled with this rigid limit in the maximum speed, the induction motor also suffers from the fact that its efficiency is very low at any speeds considerably below the maximum. On lines where the energy is obtained from water power this inefficiency is not so material, but it becomes a most serious factor on lines which are dependent on coal for their source of power. Again, while the advantages of the three-phase induction motor are considerable on lines where long non-stop runs are required, a service requiring frequent stops and high mean speeds exaggerates their inefficiency. As a result of these considerations, engineers on the Continent, in England, and in the States have for some years been working on improved forms of alternate-current motors for traction purposes. Of these the Ganz system was brought strongly to the front when it was proposed for use on the Underground Railway in London. By working two alternate-current motors in cascade, and using the rotor of the first motor to supply the stator of the second, a vast improvement was made in the economy of speed variation. In fact, it was claimed and supported by actual figures that the Ganz system would be as efficient as the direct-current one, which gained the verdict of the arbitrator. With the Ganz improvement, however, there were still required two insulated conductors, as against one with the direct-current system. While this is not an insuperable difficulty, it is a distinct disadvantage, which has been overcome by the recent improvements made in single-phase motors. The workers in this field have been numerous, and while the several motors have yet to be tried on a commercial scale, others have already given most successful results on experimental lines. Those who wish for full particulars on this subject would do well to read thoroughly Mr. H. L. Rissley's paper presented recently to the Newcastle Local Section of the Institution of Electrical Engineers. In this he describes some of the plant he inspected, during a recent visit to the United States, at the works of the General Electric Company and those of the Westinghouse Company. In each case experimental lines have been equipped for single-phase working, and in the case of the first company's system the experimental line is some sixteen and a half miles long. The trial in this case proves how adaptable the new compensated motor of the General Electric Company is. For instance, the railway runs through a town for nearly four miles, and the equipment is so designed that the motors are worked as single-phase machines in the inter-urban portion of the route, and as direct-current motors within the town. The voltage in the town is six hundred, and outside no less than two thousand volts are applied. This high alternating-current voltage is reduced by trans-

Digitized by Google

formers on the train to four hundred volts for use in two motors connected in series. Mr. Riseley gives the characteristic curves for the motor working, first with direct current and, secondly, with alternating current. These curves are remarkably alike, which shows that a motor when working under the latter conditions has all the advantages of a direct-current series motor from the acceleration point of view. Again, the apparatus being used by the Westinghouse Company on their trial line has also produced results which are eminently satisfactory. This firm employ an auto-transformer for regulating purposes, which is much more efficient than any method of introducing resistances into the motor circuit. Here, again, a high voltage is used on the trolley wire, which is reduced to about two hundred and twenty-five volts at the motor. The success of these trials and of other experiments which have been made on the Continent with motors of the single-phase type with commutators seem to point to the ultimate solution of long-distance electric traction being with the single-phase system. The advantages gained are most numerous, including a single high-voltage trolley wire, the abolition of the sub-station and its moving machinery, which would be replaced by static transformers on the train, etc. The economy in first costs would be very great. The uncertain features, such as the cost of maintenance for the new types of motor equipments, can only be ascertained after extended trials under regular working schedules. Such trials are to be made on the London, Brighton, and South Coast Railway, under the advice of Mr. Philip Dawson. The fact that such motors will work either with direct or alternating currents allows railway engineers to await the results of these trials with little anxiety, as their adoption would not necessitate the abandonment of machinery now being put in elsewhere

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### THE METRIC FALLACY.

SIR,—With regard to the article on the "Metric Fallacy" in your issue of 23rd ult., I was surprised to see quoted that of the 25 important shipyards in Germany two still use the British system of measurements. In this country, the Institution of Engineers and Shipbuilders in Scotland, with a membership of over 1,400, petitioned the Lords in favour of the metric system of weights and measures. Shipbuilders and engineers in this country would reap an advantage from the introduction of a decimal system in facilitating, as it undoubtedly would, the many calculations they have to make, and as the metric system is decimal, and is already in use by Continental nations and physicists here, it is the most suitable one.

As our people became more accustomed to the use of this metric system they would be better able to assimilate the valuable information published in Continental technical journals, and they would not be handicapped in competing for Continental and other orders as they are at present — Yours, etc. CHARLES STUART DOUGLAS.

### BALANCING CHOKING COIL.

SIR,—"Superheat," criticising the answers to Question No. 745 in your issue of Jan. 20, states "the out-of-balance current divides equally between the two halves of the choking coil, and is continuous in each." The answers he refers to are to a certain extent correct, quite as much so as the explanation given by "Superheat." Under certain conditions the out-of-balance current does not oscillate and become an alternating current in the choking coil. There are three main cases that can be considered.

1. When the out-of-balance current dealt with is less than twice the magnetising current of the choking coil. In this case the slip-rings supply a portion of the magnetising current; the other portion is supplied by the continuous out-of-balance current, which becomes an alternating current when it enters the choking coil, flowing first through one half, and then through the other in synchronism with the slip-ring current.

2. When the out-of-balance current is equal to about twice the magnetising current of the coil it supplies the whole of this current, and alternates in the two halves of the coil. At any instant when the current is in one limb of the coil it produces a back E M F. in the other half, which prevents current from the corresponding slip-ring entering this other half. Thus the out-of-balance current returns to the armature first through one slip-ring and then through the other in synchronism with the cycles of the armature.

3. When the out-of-balance current is greater than about twice the magnetising current, a portion of it flows continuously through both limbs of the choking coil. The remainder alternates first in one limb of the coil and then the other (as in Case 2), supplying the power to magnetise the coil and make up the $C^2R$ losses due to the whole current in the coil.—Yours, etc., CHOKER.

### TELEPHONE RATES.

SIR,—Your "interpretations" attached to my letter published in the *Electrical Engineer* of Jan. 20 naturally provoke a few further comments:

1. That when two persons are making a bargain one is trying to sell dear and the other to buy cheap is such an obvious proposition that it hardly needs for its demonstration a four-column article with "interpretations" by the editor.
2. Continental and American rates have little bearing on British conditions.
3. Mr. Bennett did *not* "merely assume £5. 10s. for argument's sake"; £5. 10s. was the pivot of his argument.
4. No comments.
5. Mr. Bennett says £5. 10s. as a flat rate ought to be fixed in advance and everything else made to fit. I say that this method of approaching the telephone problem is unsound, and that in the case of the municipal telephone systems, notably that of Glasgow, its unsoundness is proved by the results arrived at within three years of practical experience.

Finally, I must express my surprise that the editor of an engineering periodical should display such indifference as to what is or what is not up-to-date practice in an important branch of electrical engineering —Yours, etc.,

HERBERT LAWS WEBB.

[In replying to a reply, we have to state:

1. An editor has to interpret all articles, whether four columns or one, else he would be in queer street in a week.
2. Any rates, Continental or American, have a bearing, provided the differing conditions are considered.
3. What Mr. Bennett did say will be found on p. 26 of our issue of Jan. 6 last, but these words are important: ". . . seem that is admissible *on the basis of, say, a* £5. 10*s. rate.*" The argument being Continental, American, British corporations, *and the National Telephone Company* (the latter in certain cases) have found a flat rate of from £5 to £6 a paying one; hence if the Government is going to buy the National, its price should be largely determined by these figures and the further expenditure necessary to bring the system up to date.
4. Thanks for the smallest agreement.
5. Taking out the fixed amount, £5 10s, as not applicable to the general question, we agree that it is a debatable matter whether a flat rate or other form of payment should form the basis of calculation.

Mr. Webb is a little ingenuous in his final remark. From whence does he gather our indifference to what is up-to-date practice? We have devoted more attention to telephonic matters than all the other English technical papers

Digitized by Google

combined. Mr. Webb thinks to little purpose—but that is a mere detail.—ED, *E. E.*]

## MUNICIPAL TELEPHONES.

Mr. Bennett writes: "Mr. Webb's letter in your issue of the 20th inst. amuses me very much. Your readers will be better able to estimate the degree of importance which should be attached to it when they are informed that Mr. Webb is employed by the National Telephone Company as contract manager in all those towns in which municipal competition exists. His principal, if not sole, duty would appear to be to villify and misrepresent the municipal systems. Hence this effusion and many others, signed and unsigned."

[We have also received a telegram from the Glasgow telephone department advising us of the dispatch of a letter denying the accuracy of Mr. Webb's statements regarding the change of system in Glasgow. This letter has not come to hand in time to appear in this week's issue—ED. *E. E.*]

## ALUMINIUM.*

BY W. SMITH.

As our time is limited, without further preamble, except expressing the hope that you may be as interested in *listening* to the paper as I have been in *preparing* it, we will at once take up the subject for this evening—aluminium.

What is aluminium? Where do we find it? Aluminium is a metal having a colour very similar to that of silver. Pure aluminium, when burnished or frosted, if viewed from a little distance might easily pass for silver, but would, however, certainly be found wanting if placed in the balance. Its most characteristic property is its extreme lightness. The specific gravity of aluminium is 2·5-2·7—*i.e.*, it is only that number of times heavier than an equal volume of water. If iron and aluminium were taken in equal volumes, the iron would weigh rather more than three times as much as the aluminium.

Like so many other of our words, aluminium comes from the Latin; *alumen*, from *alas*, salt. In answer to, Where do we find it? one might almost say everywhere. Although never found in a metallic state in nature, in combination with other substances it is, perhaps, more widely distributed than any of the other metals. Common clay, which is silicate of alumina, contains about 18 per cent. It does, at first sight, appear strange that with such vast stores of aluminium around us it should be so difficult to obtain; it seems a case of water, water everywhere, and not a drop to drink. With all the opportunities plants have of taking up alumina, it has only been found in the ashes of Lycopodia-club mosses. It is even said that only two of these, Lycopodium chamœcyparissus and Lycopodium clavatum, contain alumina. Specimens of these two plants are on the table for your inspection. We cannot obtain aluminium from alumina (oxide of aluminium) by means of an ordinary furnace; a greater temperature is required, and it was the electric furnace which brought aluminium from being a laboratory curiosity at a very high price to a metal cheap enough for everyday use.

Aluminium was discovered by Wöhler in 1827, but it was Deville in 1854 who first produced the metal in an almost pure state. Deville's chemical process was as follows: Ground bauxite was mixed with soda ash (containing $Na_2CO_3 + NaHo$) heated in a reverberatory furnace. The sodium combines with silicon and alumina to form silicate of soda and aluminate of soda, $CO_2$ being expelled as gas. The mass is then washed, dissolving out the aluminate of soda. This solution is mixed with hydrochloric acid to remove the soda, the alumina then separating out as a gelatinous mass. This is aluminate hydroxide. This hydroxide is mixed with NaCl and charcoal powder to a stiff paste. The paste is made up into balls 3in. in diameter, heated, dried, and then heated in a current of chlorine gas. The salt is added to form a double chloride of aluminium and sodium ($Al_2Cl_6 2NaCl$). This double chloride is distilled and condensed. Ten parts of this salt, two parts of sodium, and five parts of cryolite, or fluorspar, are mixed together and thrown on the hearth of a reverberatory furnace. The furnace is then closed to exclude the air. The sodium acts violently on aluminium, which collects in the metallic state beneath a layer of slag containing the sodium chloride and the cryolite. Metal made by this process contains much silica and iron. Samples of bauxite and cryolite, also prepared sections and photographs, are shown on the table.

For cooking utensils and for table use aluminium is very suitable, a great point in its favour being due to the fact that its salts are not poisonous. It seems a pity that its use in these capacities is not more general.

In considering the advisability of employing aluminium in place of the generally-used copper as a conductor for electrical energy, we may ask ourselves two questions: Is it possible? Is it practicable? As to its possibility there can be no doubt whatever; it conducts electricity to a degree of from about 55 to 62 per cent. that of copper. With regard to the practicability, it is more a commercial than an electrical question. As a heavily-insulated conductor it is out of court, but for many positions as an overhead bare conductor, or a lightly-insulated cable laid on the solid system, there appears to be many points in favour of aluminium. This is at the present price of about 2s. per pound. Who knows but that future improvements may result in such a further drop in price that copper may have to face a very formidable rival indeed. The electrical conductivity of aluminium wire appears to vary very considerably. Some wire purchased in the open market had a conductivity only 55 per cent. that of copper. Some special wire, very much higher in price, was 62 per cent. that of copper. If costs be carefully worked out, it appears that we can afford to pay rather more than twice the price per pound for aluminium than for copper.

Although the relatively larger diameter of aluminium is against its use for overhead work, perhaps the greatest drawback is the trouble found in jointing. There does not appear to be a reliable solder. This statement may appear to you somewhat paradoxical, seeing that on the table here are a number of soldered joints. All these joints have been prepared for the paper this evening, and I must say that very little difficulty has been encountered in making them. It is said, however, that soldered joints only last about three months; these have been made about six weeks. They do not, however, appear to have deteriorated, and we will presently examine some enlarged views of these joints on the screen. Burgess gives the following as a good solder for aluminium:

| | | |
|---|---|---|
| Zn | 21 | } 100. |
| Sn | 76 | |
| Al | 3 | |

Electrical welding appears to require special apparatus; time has not enabled me to make more than a few experiments in this direction. The Cowles was the first electrical furnace for production of aluminium, but was more fitted for producing alloys than the pure metal. The two methods, which are practically identical, now in use for separating aluminium are the Heroult and the Hall processes. Heroult is a Frenchman, Hall an American. Aluminium after being taken from the furnace may be cast, rolled, drawn, pressed, etc., as desired. It is rolled into leaf fine enough to rival silver for decorative purposes. Photographers use its powder for the "flashlight." You will see on the table some slips for the microscope made from aluminium sheet. The cell, and seating on which to fix the cover glass, together with the slip itself, are all stamped and pressed from one piece. They are frosted by immersion in a hot solution composed of the following ingredients:

| | |
|---|---|
| $H_2O$ | 87 |
| NaHo | 10 |
| NaCl | 3 |

After being in this solution about half a minute they are taken out and rinsed under the tap. They are then placed in strong nitric acid for a few minutes, rinsed under the tap, and dried in warm sawdust. Some of them have been roughened first with powdered pumice, others by means of the sand blast.

[The author then took advantage of the aid offered by

* Paper read before the Birmingham Electric Club on Jan. 14, 1905.

Digitized by Google

photography to illustrate his remarks. Owing to difficulties in reproduction for printing, we are only able to give a limited number of these illustrations, and have selected those which are mostly original.]

FIG. 1.—This is a section of bauxite × 20. It does not make a particularly good object, partly owing to its colour and partly owing to its friability. It is a difficult object to prepare. It is found in Ireland, France, and the United States. It is rather variable in its composition, but generally contains about 56 per cent. of alumina. In appearance

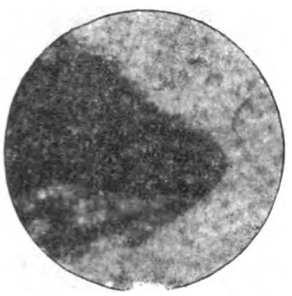

FIG. 1.

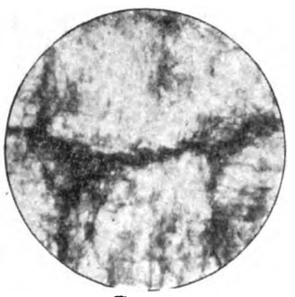

FIG. 2.

it is just like baked clay. In the Heroult method, bauxite is mixed with sufficient carbon to reduce all the impurities to the form of metals—silica to silicon, titanic acid to titanium, etc. Mixture is then melted in an electric furnace using a carbon pole, the material itself being fed into the arc, the melted alumina forming the other pole. An alternating current of low potential is used. Impurities collect as metallic alloys. The alumina is pure and above the alloys.

FIG. 2.—Section of cryolite × 20. Cryolite is a double fluoride of aluminium and sodium ($6NaFAl_2F_6$). It is mainly obtained from Arksut Fiord, Greenland. Used for electrolyte in Heroult's process for making aluminium. Melts at 800deg. C.; it is then transparent and dissolves alumina.

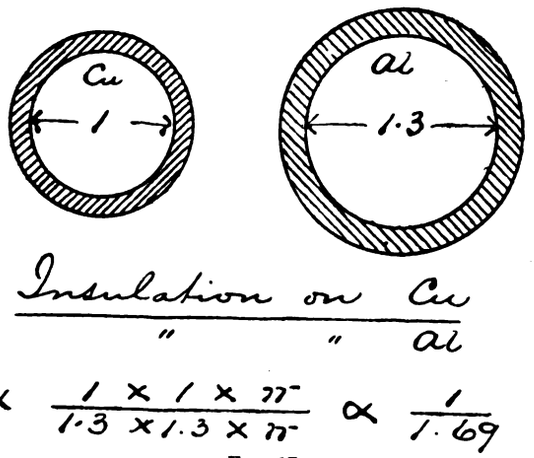

FIG. 13.

FIG. 13.—On the supposition that the aluminium has a conductivity 60 per cent. that of copper, we have:

$$\frac{\text{area of copper}}{\text{area of aluminium}} \propto \frac{60}{100} \propto \frac{3}{5}.$$

$$\therefore \frac{\text{diameter of copper}}{\text{diameter of aluminium}} \propto \frac{\sqrt{\frac{\pi}{4 \times 3}}}{\sqrt{\frac{\pi}{4 \times 5}}}.$$

$\therefore$ if diameter of copper = 1,

$$\text{diameter of aluminium} = \frac{\sqrt{5}}{\sqrt{3}} = 1{\cdot}3 \text{ (approximately)}.$$

Now, for equal insulation to leakage, as the leakage area is greater, the insulating material must also be thicker in a like ratio.

$$\therefore \frac{\text{insulation on Cu}}{\text{insulation on Al}} \propto \frac{1}{1{\cdot}69},$$

FIG. 14.—For equal losses, diameters of copper, aluminium, and iron are in the ratio 1 : 1·3 : 2·5. Taking 50lb. as maximum pressure per square foot due to wind, and taking an effective force of 30lb. in allowing for rounded surface of wire, with copper 1in. in diameter and aluminium and iron in their proportions, the thick lines will give an idea of the several resultant pressures.

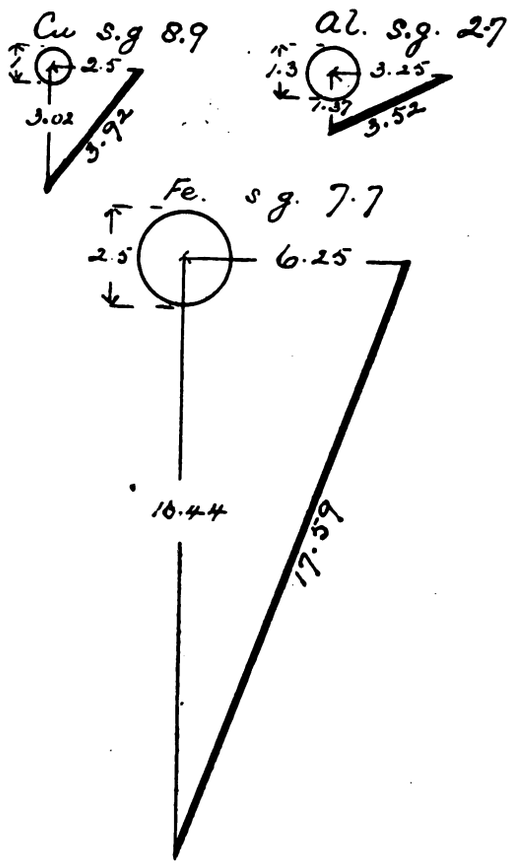

FIG. 14.

FIG. 15.—(I.) Wire is pulled through the slot, riveted, and then let back. Pull is taken up by the riveted head on wire. (II.) Two parts, male and female screws, make up the coupling; wire is bent over as shown, coupling screwed up, and a pin driven through to prevent untwisting.

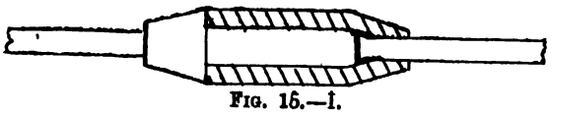

FIG. 15.—I.

FIG. 15.—II.

FIG. 16.—(I.) Grub screws in the coupling or sleeve hold the stranded conductor. (II.) Nuts screw down the taper and firmly grip the conductor. The fitting is in halves, with fitting pieces to keep in alignment. (III.) Tapered conical wedges, fitting over the middle, single, or seven strands, when driven home splay out the outer wires. Thus the conductor is held tighter as pull increases.

FIG. 16.—I.

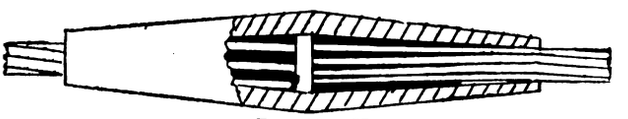

FIG. 16.—II.

FIG. 16.—III.

FIG. 17.—This joint, unless particularly well made, pulls out at much less than the breaking strain of the wire.

Digitized by Google

FIG. 18.—Round wire is flattened and riveted. Rivets must be aluminium or aluminium bronze to prevent electrolytic action.

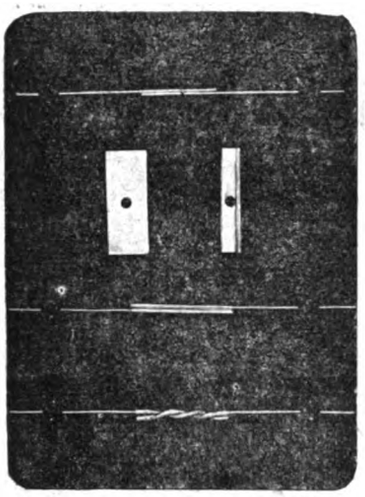

FIG. 17.

FIG. 20.—This is a joint—Neild's patent—made in overhead wires. Wires are placed in a sleeve; the sleeve has a recess, and is filled in with solder. Somewhat similar in style to the well-known Britannia joint.

FIG. 18.

FIG. 21.—Section through one of these joints (20). × 40. This is cut off at nearly the largest diameter of the cone. Polished. Etched with dilute HCl. The microscope aids our eyes and enables us to follow the finer details that otherwise would be invisible. Although at

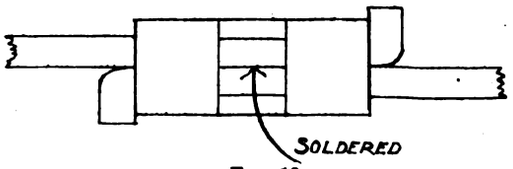

FIG. 19.

present one cannot claim an exact diagnosis by means of microscopical examination, there is no doubt that it is a wonderful aid to our knowledge of metals and their alloys. Many of us have seen a blacksmith look with critical eye at a fractured piece of iron or steel, and heard the grunt,

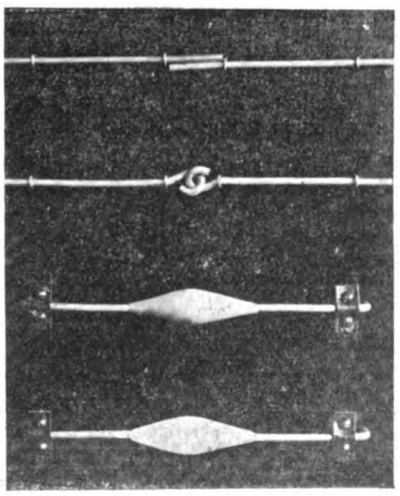

FIG. 20.

either of approval or disapproval. A tool that has been broken on the lathe will often show unmistakable signs of having been "burned." The microscope enables us to carry on our investigations with greater discrimination. To prepare metals for the microscope they must first be polished. Now there is polishing and polishing. In an engineering workshop one often hears the remark about a job that "it is highly polished and deeply scratched." This sort of thing would be useless to the microscopist. Under a medium power it would look something like a sheet of corrugated iron roofing. To be suitable for the microscope all scratches must be eliminated, and this is by no means an easy matter. When working

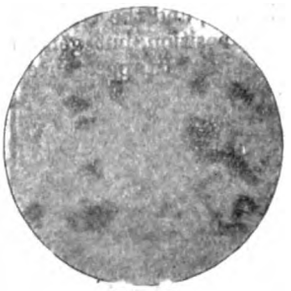

FIG. 21.

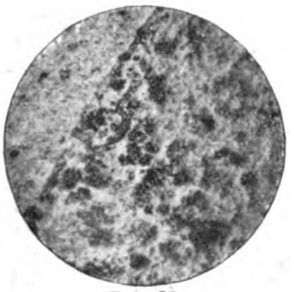

FIG. 22.

at the bench we say that the rough file should have nothing to do except remove the chisel marks, the smooth file remove the cuts of the rough file, and after draw-filing the emery cloth should simply have to polish. To prepare metallic surfaces for the microscope, we only begin to polish where the fitter leaves off. See that the surface is as good as can be obtained with No. 1 emery cloth; then use finer grades down to 0000 cloth or paper. In using these grades of cloth it is as well to make sure before using a finer one that there are no scratches but those due to the paper you are using. The polishing must then be done on stretched washleather with jewellers' rouge. Finally, take the object in the left hand, and holding a soft clean pad of washleather in the right hand, polish with a little precipitated calcium sulphate.

FIG. 22.—Same as Fig. 21, but × 60.

FIG. 23.—Same as Fig. 21, but × 80.

FIG. 23.

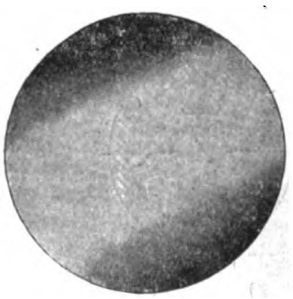

FIG. 24.

FIG. 24.—Soldered joint in aluminium wire not etched. × 8. To solder aluminium the metal must be as hot as possible when joint is just being finished. The main difficulty lies in well covering the surfaces that are to be soldered. A scratch brush will do, but personally I prefer to scrape the surfaces that are to be joined with a knife while they are covered with melted solder. If the joint, solder, and knife be well cleaned in a little benzol the surfaces will tin satisfactorily. As soon as possible, while the parts are well heated, press firmly together.

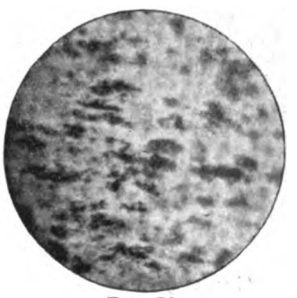

FIG. 38.

Gentlemen, we have looked at aluminium from several points—what it is, and from where it is obtained, its manufacture, and a few uses to which it is put, with suggestions for its further employment. We have considered briefly its fitness as an electrical conductor. Soldering the metal has been brought to your notice, also a new method of welding joints without softening the line wire. Some explanation, with examples and illustrations of its metallography, have been placed before you; samples are on the table for your inspection.

I trust that some of these things will provoke a discussion this evening. There may be some who do not feel confident enough to discuss the questions from an engineering point of view; but perhaps these gentlemen may have the pleasure of living in houses the grounds of which are fertilised by the pellucid waters of the meandering Rea. They will then, no doubt, be able to enlarge on the botanical part of the paper. I have to thank you for giving me such a patient hearing.

## SMOKE PREVENTION.

The Absolute Smoke Abolition Syndicate, Limited, are giving a number of demonstrations of their process daily from 11 a.m. to 1 p.m. and 2 to 4 p.m., at 26, Page-street, Westminster, to which steam users, their managers, engineers and stokers, are invited to inspect. On Saturday afternoon, special exhibitions are given for managers and steam users who cannot attend during factory working hours.

The invention they are showing is by Mr. Greaves, who is not unknown in the engineering world, and consists of an apparatus the object of which is to prevent smoke nuisance and to save coal. It consists principally of a second bridge of pipes or arches made of a special fire-resisting material and placed into the flue about 18in. behind the usual bridge. The flue between the two bridges is lined with firebrick at the bottom. The firebars are very deep with thin edges, and consequently expose large surfaces to the incoming cold air. They are thus kept from melting or burning, and should therefore last longer than the ordinary ones. The arrangement of the air

Digitized by Google

spaces allows the greatest supply of air through the back bars further from the door, where the fire burns fiercest. This ought to tend to more complete combustion and consequently less smoke. The latter half of the bars are set upon a rising plane, making the weight of fire less at the back end, and thus giving a better passage to the incoming air at the distant end of the furnace, where it is most needed to ensured complete combustion. The bridge is so constructed that it can be used as an ordinary solid bridge or a controlled split from the boiler front, as may be desired. All products given off by the furnace must pass the second bridge, which becomes incandescent after firing, and its object is to destroy the carbon smut while it is still in its gaseous form, and thus prevent it from developing into black smoke.

Messrs. Burstall and Monkhouse have made a number of experiments with a Lancashire boiler before and after Mr. Greaves's arrangement had been fixed, and in their report they conclude that: "The result of the test shows that with the Greaves apparatus smoke may be done away with for all practical purposes, while at the same time a saving of over 7 per cent. in fuel may be obtained, even in boilers which are working economically before the apparatus is fitted. With boilers working uneconomically, the saving may be much greater than this, as the means taken to cure the smoke are not, like many smoke-preventing appliances, wasteful in themselves by the admission of an excessive amount of air. With the Greaves apparatus no excess air is admitted behind the bridge, but the unburnt gases are ignited by the incandescent 'honeycomb,' causing complete combustion."

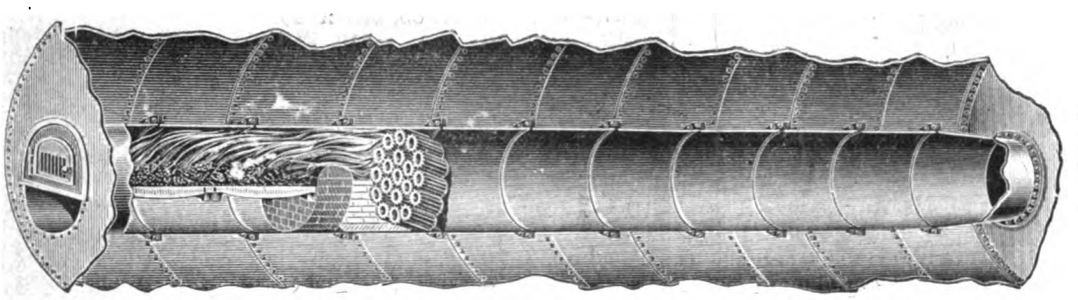
During our visit to Bridge-street a boiler was fired with a kind of coal-dust said to have cost 11s. per ton delivered, and only a thin film, more like steam, was emitted from the chimney. We are informed that the first cost is small, and that a boiler can be fitted within 24 hours. The firm maintain for 12 months, and guarantee against fines for smoke nuisance.

## A NOVEL INCANDESCENT LAMP.

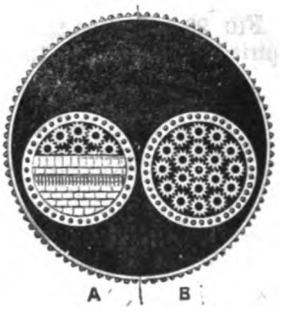
At a recent meeting of the Berlin Electrical Society (Jan. 17) Dr. von Bolton and Dr. Feuerlein delivered a lecture on the new tantalium incandescent lamp brought out by the Siemens and Halske Electric Company, making some interesting experimental demonstrations. Endeavours made of recent years to cheapen the cost of electric lighting, so that this might become a more powerful competitor to incandescent gas lighting, have given rise to the construction of incandescent lamps with an especially low consumption of energy per candle-power. Any attempts made in this direction in connection with carbon-filament lamps have, however, failed to be successful. While the luminous power of an illuminant increases as the temperature of the latter is raised, a carbon filament burning with 3·5 watts per candle can only stand an increase beyond the normal temperature of about 1,700deg. C. for a short time, after which the filament disintegrates, the bulb becomes black, and the lamp will soon be destroyed.

This suggested the idea of looking for such substances as might stand a higher temperature without being injured, and, after a series of thorough preliminary experiments, Mr. von Bolton, of the Siemens and Halske Company, found tantalium (the melting point of which is beyond that of platinum, lying at about 2,000deg. C.) to be such a material. Tantalium is very widespread in nature, being recovered in large amounts from the tantalite and columbite ores of Australia, America, Norway, and Sweden. After having undergone different purifying processes, it is melted in vacuum and drawn out to long circular filaments of 0·05mm. and 0·035mm. diameter. This wire is stretched on supports carried in an ordinary incandescent lamp bulb, and exhausted as is a carbon-filament lamp. The tantalium filament is formed into a zigzag round these supports, of which there are 11 at the top of the lamp and 12 at the bottom.

Tantalium lamps have an efficiency as high as 1 c.p. for 1·5 watts, and are designed in three types—for 16 candles and 110 volts, 25 candles and 110 volts, and 32 candles and 220 volts respectively. Their average life is said to be 1,000 hours, while their most economical life is from 400 to 600 hours.



Sectional Longitudinal Elevation.



Cross Sections.

This new lamp is said to be less sensitive in regard to fluctuations in pressure than carbon-filament lamps. The light from the lamp is very white, as would be expected from the high temperature employed.

## FORTHCOMING EVENTS.

FRIDAY, JAN. 27.

**Municipal and County Club.**—House dinner.

**Automobile Show.**—At the Crystal Palace (to Feb. 4).

SATURDAY, JAN. 28.

**Permanent-Way Institution.**—At 2.30 p.m. (at the Institution of Civil Engineers), annual winter meeting. At 6 p.m., annual winter dinner, Mansion House Station Restaurant.

**Institution of Electrical Engineers (Students' Section).**—Visit to the G.P.O. Central Telephone Exchange.

MONDAY, JAN. 30.

**Faraday Society.**—At 8 p.m., "Mass Analyses of Muntz's Metal by Electrolysis, and some Notes on the Electrolytic Properties of this Alloy" (illustrated), by Mr. J. G. A. Rhodin; "The Equilibrium between Sodium and Magnesium Sulphates," by Mr. R. B. Denison; "Refractory Materials," by Mr. E. Kilburn Scott.

TUESDAY, JAN. 31.

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Some Points on the Selection of Electric Cables," by Messrs. L. B. Atkinson and C. J. Beaver.

WEDNESDAY, FEB. 1.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "The Present Electrical Equipment of the London County Council Tramways," by Mr. J. W. Anson.

**Institution of Civil Engineers (Students' Section).**—Visit to the National Physical Laboratory, Bushy House, Teddington.

THURSDAY, FEB. 2.

**Chemical Society.**—At 8 p.m., general meeting.

**Rontgen Society.**—At 8.15 p.m., Dr. Clarence A. Wright will read a paper, "Some Points in the Construction of a High-Frequency Machine," and will show probably some novel exhibits. Messrs. Newton and Son will show "Dr. Thurstan Holland's X-Ray Diaphragm Compressor."

**Civil and Mechanical Engineers' Society.**—At 8 p.m., "The Mechanics of Flour-Milling," by Mr. A. R. Tattersall.

FRIDAY, FEB. 3.

**Junior Institution of Engineers.**—At 8 p.m., "Recent Developments in Electric Lighting," by Prof. H. T. Davidge.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "The Electric Equipment of Automobiles."

SATURDAY, FEB. 4.

**Institution of Electrical Engineers (Glasgow Section).**—At 7.30 p.m., annual smoking concert at the Grosvenor Restaurant, Glasgow.

**The Dynamicables** will hold a dinner at the Trocadero on Feb. 8, preceded by a council meeting.

## THE ELECTRICAL OPERATION OF TEXTILE FACTORIES.

The paper read by Mr. H. W. Wilson before the Manchester Section of the Institution of Electrical Engineers on the 17th in reference to the above subject was discussed on the same date before a good attendance of persons interested in this latest development of electrical enterprise. The paper was summarised in our issue of last week (p. 75), and it may be noted that the point principally touched on in the summary, that of cost, was the keynote of the discussion. It will be seen that the general feeling was that the public electricity supply schemes are unable to compete on price alone with present-day methods in the majority of cases (whatever may be the success of locally-installed electric plant), and so the business apparently will have to be built up on similar lines to the present supply for lighting purposes, where convenience, cleanliness, etc., are more to be considered than strictly comparative costs, light for light. The following tabulated advantages, mentioned in the paper, are therefore extracted for special notice in connection with this matter, and the item on p. 830 of this periodical for Dec. 9 last (concerning the application of electric power to the spinning and weaving mills at Malaga, where a saving in costs of 20 per cent. upon an output of 2,500 h.p. is mentioned) may further be appreciated for reference, especially as an English firm (Mather and Platt) was responsible for the plant.

1. The mill and the engine-house can be placed each in its most convenient situation without any regard to their relative positions.
2. The internal arrangements of the mill as regards shafting, gearing, and rope drives, etc., are greatly simplified and their costs reduced. The flexibility as regards extensions is, of course, obvious.
3. The grouping of machines is much less arbitrary than in a mechanically-driven mill, as the motors and the comparatively light shafting required by them can be placed where most convenient.
4. The reduction of a chance of breakdown, which would stop the whole mill, to a minimum.
5. The ease of running one section for overtime or on special work.
6. The reduction of the maintenance and depreciation charges.
7. The greater steadiness of drive which can be obtained under suitable conditions with a subsequent permissible higher speed and increased output.
8 The reduction in the total capital cost of the mill per spindle or per loom with a factory of above a given size.
9. The possibility of keeping a constant check upon the results obtained in each department of the factory.

The discussion was opened by Mr. C. D. TAITE from the chair, who commented on the appropriateness of the paper, Lancashire being the home of the textile industry. He thought the ·33d. per unit mentioned would be too low a rate for electricity works to compete with, as none yet supplied at that rate. Mr. Woodhouse had recently mentioned a rate of over a halfpenny, and he himself thought that "the higher we go the better."

Mr. SEATON was considerably struck with the originality of the paper, as, while other literature on the subject depended largely on Mr. S. B. Payne's researches, this person's name is only quoted once by Mr. Wilson. He mentioned the following obstacles in the way of introducing electricity into textile factories: (1) managers' scepticism as to the advantages of electrical working; (2) lack of expert advice, although this was a delicate point to make in such company; (3) opposition from mill-engine builders, steam-turbines especially being awkward opponents; (4) the economical working already attained would require a lot of beating. At present, to his knowledge, a horse-power per annum cost only 15s. 6d. for coal, and if any electric works manager could beat that, he would like to serve an apprenticeship with him. Further, there was the possibility of competition between plant makers and power makers, but the latter must come down to at least a halfpenny per unit. With most electrical generating stations this would mean "dumping," and that is only possible if one can find a certain number of other consumers prepared to pay through the nose to make up for the loss thus occasioned. As to the suggestion that other undertakings, such as coal mines, should take power by night to make up for this, he could imagine them, in reply, quoting the scribe Innocens, "Go thou unto the hottest place!"

Mr. W. B. WOODHOUSE was in agreement with Mr. Wilson on most points. He thought the knowledge of millowners as to their own costs was over-rated. The 15s. 6d. per horse-power per annum mentioned was probably made up of the total cost of coal divided by maximum load × total hours worked. He knew of mills with no less than five belts between machines and engines, most of the belts being like polished silver, and as the weather changed so did the speed of the machines. The advantages of obtaining power outside the works included the facts that there was less land to pay for, less worry to be encountered, and the capital could be reduced very considerably, or could be used more profitably in extensions to the mill itself. The ·3d. to ·35d. rate per unit he thought was too low for power companies to touch, but this low cost was not in accordance with his experience in Yorkshire, where the average equivalent price per unit would be more like 1d., and at lowest ½d., including capital charges of 10 to 15 per cent., the average efficiency being 50 per cent. He thought that single-phase reaction motors should be more successful than direct-current machines.

Mr. JOHN SHAW pointed out that America had had most experience in mill driving by electricity, and at one time their advocates of electric driving could not recommend it for economy when the engine-house was anywhere near the mill, but now there were no less than 27 mills built with self-contained electric power stations. It was safe to work at the maximum speed by electrical means, as the rate of speed was so constant, whereas with mechanical driving they had to be satisfied with a lower average speed on account of the greater variation, through pulleys slipping and accelerations breaking threads and so shutting down machines. He thought 2 per cent. a safe increase in speed. This steadier drive meant a further economy by increasing the number of machines that could be tended per operative, and therefore would lower the piecework rates. He agreed with Mr. Woodhouse that the ·3d. figure was too low, ·4d. to ·45d. being more like the cost per unit. An important point based upon his experience was that the first cost is less for the electrical installation than for mechanical driving gear. As to durability, although they could not yet point to 40 years' experience of electric driving, on electrically-driven mills 11 years of age no motor had yet been replaced. Motors had got to their topmost efficiency by now, and would never need superseding

Mr. WHITEHEAD gave evidence to show that mill managers were well posted as to the efficiencies and costs of their establishments, and were not guided by rough approximations, as Mr. Woodhouse surmised.

Mr. GAMLEN also agreed that the ·3d. to ·35d. figures were too low for even power companies, and thought that a halfpenny was nearer the figure. As to being sent "unto the hottest place," he took it that this meant down the coal pits, which was just where he hoped to carry his electric power.

Dr. BOWMAN spoke from practical experience of mill work in all its departments, and gave technical reasons for the difference between the efficiencies of Lancashire and Yorkshire mills. In many mills very considerable trouble was taken to find the exact costs. In one mill where diagrams were taken three times daily there was an average load of 90 per cent. It was heaviest on Monday mornings, due no doubt to the Monday feeling, and with belting as with men: undue moistness made them tight. The cost came to ·22d. per horse-power per hour, which equalled 33d. per unit, so he could endorse the much-questioned figures in the paper. He had included 10 per cent. for capital charges, and the cost of upkeep was only 2½ per cent. This mill had 80,000 spindles with 850 i.h.p, and he could fit up a mechanically-driven mill, as to plant and transmission, at £10 per indicated horse-power. He pointed out the advantages of rope driving over belting, and himself was

Digitized by Google

the first to run a mill of over 1,000 h.p. with ropes—which cost in this case £400 against belts £1,500. He was told at the time that he had better hang himself with the ropes, but as his experiment was successful there were several hats (considered) eaten as a result. As regards efficiencies, he found more friction losses on the machines themselves than in the transmission gear. Plenty of mills, however, required altering to electric driving through inefficiency in transmission, the owners believing that the greater the load on the engines the more work was being done. He thought that estimates for electric power installations generally required revising, as they were too high to be of service.

Mr. C. C. ATCHISON was of the same opinion as previous speakers as to the impossibility of electric supply systems' rates being sufficiently low to tempt textile factory owners, owing to the extremely constant load. He had been told by the owner of a 700-h.p. mill that his own proposed charge for power was *three* times too much. A good deal might depend, however, in a technical knowledge of mills, and he thought that if the power companies had specialists in this line they could talk matters over more satisfactorily with millowners, and could possibly point out advantages that neither a mill-owner nor an ordinary electrical man could appreciate. He considered that ·75d. per unit was the lowest possible to sell at, but if the Board of Trade permitted overhead lines, he believed there would be more chance of reaching outlying mills without the comparatively prohibitive costs of underground work.

Mr. H. W. WILSON, in his reply, said that the ·3d. was not put in for fun, and emphasised that his figures were correct. He did not think piecework prices could be reduced by electric driving. The halfpenny per unit suggested by several speakers was in his opinion too high to be of use to many millowners, and he had known cases where this rate had been refused by them. He condemned gas-engines for the work, and especially for driving alternators in parallel, as an invention of the Evil One.

Mr. E. W. COWAN, in proposing a vote of thanks to Mr. Wilson, commented on the unusual freedom from statements and controversy of an interested trade nature in the paper and discussion.

Mr. G. F. METZGER seconded the vote.

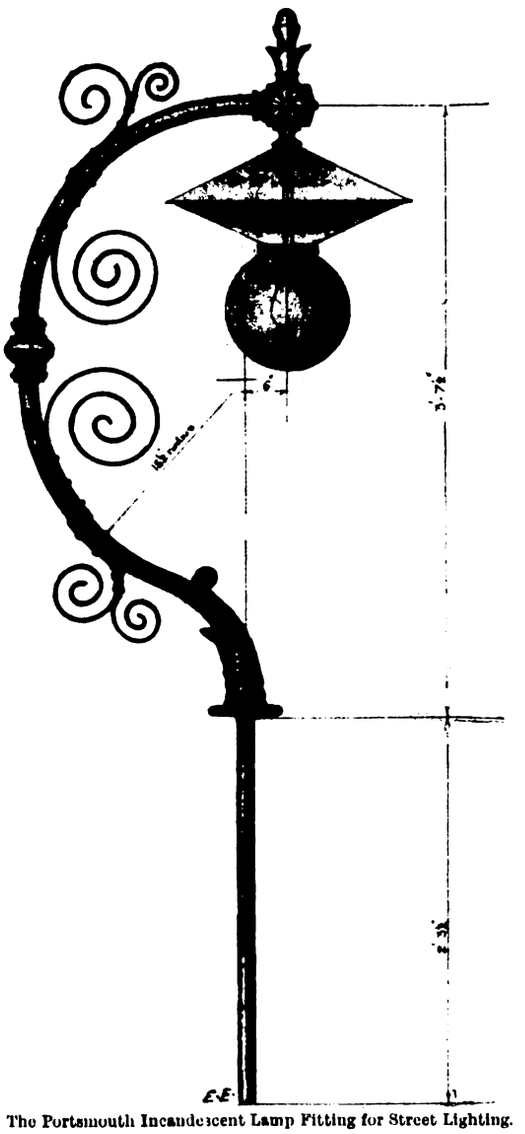
## TRADE NOTICES AND NOVELTIES.

### Water-Turbines.

From Mr. Alph. Steiger, M.I.C.E., 28, Victoria-street, Westminster, S.W., the London representative of Messrs. Escher, Wyss, and Co., of Zürich, Switzerland, and Ravensburg, Germany, we have received a new catalogue of water-turbines. The prominent position taken by Messrs. Escher, Wyss, and Co. as manufacturers of this special class of machinery is well known. Their turbines are in demand in every civilised country where water power is available for utilitarian purposes, and their name is associated with every important water-power scheme which we can call to mind. No matter whether it be Switzerland, Germany, France, Italy, Spain, India, the vast continent of America, these small islands, or elsewhere, the result is the same. The success of the firm may be attributed to the advantage of position which secures them a great local demand for hydro-plants, this being undoubtedly responsible for the development of the water-turbine to its present state of perfection in Switzerland, and we all know that the conditions which govern the satisfactory running of such plants are the same everywhere. It is especially interesting to note how the average power of each unit has steadily increased during the last few years. Thus in 1889 the average power per unit of plant installed was 104 h.p., while for the years 1895, 1900, 1902, and 1903 it was respectively 133 h.p., 311 h.p., 550 h.p., and 743 h.p. This is due to the increased employment of large units, a few additions of 10,000 h.p. each, such as those at Niagara Falls, causing, of course, an appreciable rise in the average. In all Messrs. Escher, Wyss, and Co. have supplied to the end of 1903 over 3,500 turbines, representing an aggregate of more than 600,000 h.p. They have paid special attention to the design and construction of two types of wheels—namely, the Francis turbine and the high-pressure impulse wheel. The principal features of these types are described and illustrated in the catalogue under notice, which also includes a mass of information relating to hydro-plants generally, together with a number of examples of installations erected in different parts of the world. Readers interested in the utilisation of water power should certainly obtain a copy of this catalogue.

### New Incandescent Lamp Support.

The accompanying illustration shows the incandescent electric lamp support and fittings as used for street lighting in Portsmouth. This design is a strictly original one, having been prepared for the Corporation by Mr. W. S. Foale, the engineer and manager of the electric supply undertaking. It will be seen that the lamp is enclosed in a clear globe, over which an inverted reflector is placed, which spreads the light in all directions. This type of reflector tends to equalise the illumination at all points of the roadway much more than the ordinary type, which rather concentrates the lighting on points near to the lamp column. With the use of incandescent lamps for street lighting, the details of the fittings make or mar the



The Portsmouth Incandescent Lamp Fitting for Street Lighting.

system, and we are pleased to reproduce the illustration herewith, which shows the type which has been most successful at Portsmouth.

### Simplex Conduit Erection and Wiring.

Together with the list dealt with in our issue for Jan. 20, we received from the Simplex Steel Conduit Company, Limited, a copy of their conduit wiring hand-book, which has been revised and brought up to date. The author of this little book is Mr. L. M. Waterhouse, M.I.E.E., A.M.I.C.E., engineer and general manager for the company, than whom no one could be better qualified to write upon the subject. His object, as explained in the preface, has been to give practical and detailed information concerning the various parts of the Simplex system and their application in practice. The best arrangement and design of circuits, and particulars of up-to-date installation methods, have also been included, in order to assist the observant wireman to an intelligent knowledge of how best to meet the varying requirements of conduit installation work, as well as to lead him to an appreciation of the capabilities of the system to carry out each and all of those requirements efficiently and economically. It is essential that the modern wireman should know all about conduit work, and to him especially the book in question will be invaluable for reference purposes.

## Single-Phase Motors.

We are informed by the Rhodes Electrical Mfg. Co., Limited, 70 and 71, Bishopsgate-street Within, London, E C., that they are now manufacturing a single-phase motor of exceptional value to supply engineers, inasmuch as the machine has a very powerful starting torque and takes only a small amount of current in starting. It is a combination of a repulsion and induction machine, having constant speed when the induction side is cut in, and being reversible by means of simply changing two connections through the medium of an ordinary chopper-type switch. A 5-b.h.p. six-pole motor of the type in question, wound to operate on a 50-cycle circuit, has an efficiency of 82 per cent. and a power factor of 81 per cent. This motor will start 2½ times its full load running torque comfortably with a starting current not exceeding about double full load value, and will attain its rated speed in a smooth and gradual manner. We hope to give illustrations and further particulars of the above in a future issue.

## "Bristol" Novelties.

Many novelties are included in the latest catalogue issued from the Bristol Electric Safety Lamp Works, 40, Great Smith-street, Westminster, S.W. We have selected two for illustration. The first of these (Fig. 1) is a fishing light, consisting

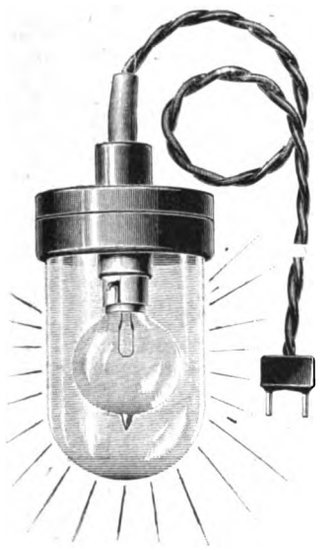

FIG 1.

of an incandescent lamp enclosed in a special waterproof fitting, and attached as shown to a length of flexible wire. This lamp is intended to be lowered into the water so as to attract fish to the bait. Fig. 2 shows a new fitting for suspending an electrical reading lantern from the top rail of a bedstead. It consists of an adjustable clamp, to which a socket for the lantern hook is fixed by means of a universal ball joint. No doubt this fitting will be widely appreciated. For the rest

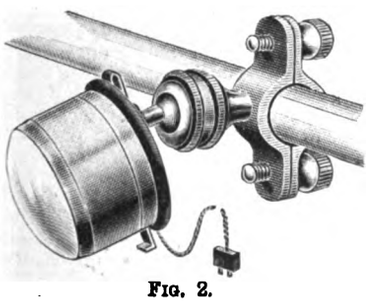

FIG. 2.

the catalogue deals with portable accumulators and electric safety lamps of various patterns, cycle lamps, small dynamos for charging purposes, measuring instruments, carriage lighting sets, and other well-known "Bristol" specialities.

## G. E. C. "Switchboards" List.

From the General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., we have received a copy of their new "switchboards" list. Several fine switchboards recently erected by the firm in this country and elsewhere are illustrated in the front portion of this publication. Then we have some pages of information relating to the apparatus listed, followed by separate descriptions of the different panels for continuous-current switchboards, representing the firm's latest practice, alternative arrangements being included in each case, together with a diagram of connections and full particulars. Next come traction feeder pillars and panels; field excitation columns; resistances; details of standard cast-iron, angle-iron, and supported pillar frameworks for switchboards; 'bus-bar brackets and insulators; 'bus bars; holding-down bolts; slab-fixing bolts and screws; slate sub-bases; stay rods and turn-buckles; supports for 'bus bars; ground detector panels; lamp brackets; and swinging instrument brackets. The back portion of the list deals with panels for alternating-current switchboards, high-tension switches, and circuit breakers, lightning arresters, choking coils, liquid resistances combined with magnetic blow-out arresters, and high-tension fuses. Much care has evidently been taken in compiling this list so as to facilitate reference to the different items included. The issue of the list by the General Electric Company, Limited, as a separate section of their catalogue has been found necessary, we understand, owing to the increasing demand for panels for traction and lighting systems, to cope with which the company have recently added very considerably to this department of their business, thus placing themselves in a position to deal promptly with all orders.

## I.T.E. Limit Switches.

Users of electrically-driven machinery have frequently found it essential under certain conditions to be able to open the electric circuit instantaneously from distant points irrespective of the load, either by hand or predetermined mechanical conditions. The I.T.E. limit switch, of which we have particulars from Messrs. Robert W. Blackwell and Co., Limited, 59, City-road, E.C., is claimed to be a thoroughly reliable piece of apparatus for this purpose. It consists of the now well-known I.T.E. circuit breaker, but with a shunt or fine-wire coil substituted for the usual series actuating coil, passage for the main current still being through the switch bridge. The shunt coil may be so wound as to be operated from the main circuit, or, if more convenient, from a local or battery circuit according to the wishes of the user. By closing the shunt-coil circuit the limit switch will instantly open in the manner now so familiar to users of circuit breakers, and the main circuit will be interrupted. It is possible, where required, to still retain the series coil in combination with this fine-wire coil, the apparatus being then a circuit breaker and limit switch combined, giving protection also in the event of "overload" or "short-circuit" conditions. Examples of the practical application of these switches are given in a recently-issued section of Messrs. Robert W. Blackwell and Co.'s catalogue 59, their use in connection with travelling and jib cranes, on railways, in car-sheds, on printing presses and lifts, and as speed controllers being specially dealt with.

## Catalogues, etc., Received.

DYNAMOS AND MOTORS.—The Electrical Company, Limited, 121 to 125, Charing Cross-road, London, W.C., have sent us Sections D and E of their new list No. 1. The type of machine dealt with in these sections completes the series of slow-speed continuous-current machines, of which those in the preceding Sections A to C of the same list constituted part. Up to the 16-h.p. size, machines of the type in question may be used as motors, and on account of their slow speed and high efficiency are particularly suited for driving printing presses, paper machines, etc. As dynamos they may be advantageously used as exciters for direct coupling with three-phase generators, or they may be direct coupled to small steam or gas engines.

MISCELLANEOUS.—In addition to the list noticed above, we have recently received from the Electrical Company, Limited, a number of prints illustrating polyphase motors and generators of the different types supplied by them; also a leaflet dealing with carbons for flame lamps; and a card illustrating type B Nernst lamp, of which, we understand, there are three millions now in use. This lamp gives 35 c.p. at a guaranteed current consumption not exceeding that of an ordinary 16-c.p. lamp.

SIEMENS BROS.' PUBLICATIONS.—Several batches of leaflets have recently reached us from Messrs. Siemens Bros. and Co., Limited, York-mansions, York-street, Westminster, S.W. The latest includes the firm's standard specification 9-A for their large H machines; also the following diagrams of connections—viz., 150-M A motor starters; G machines (shunt and compound generators and motors); six-pole H machines (shunt and compound generators); eight-pole H machines (shunt and compound generators). These are intended to be filed with the respective leaflets and price-lists to which they belong. A useful form of binder is supplied by Messrs. Siemens Bros. for this purpose. It may be added that the diagrams in question are most excellent of their kind, and should prove of considerable value to the firm's customers. From the same source we have also a circular describing an interesting telpher line erected at the Blackburn Corporation gasworks for the purpose of handling coke from the retort-house to the coke store, a maximum distance of 240ft.

CIRCUIT BREAKERS.—From Messrs. Ernest F. Moy, Limited, Greenland-place, Camden Town, N.W., we have an illustrated sheet describing their circuit breakers type No. 16, single pole for continuous-current circuits up to 550 volts. These breakers are compact in appearance, and seem to be very substantially constructed.

Digitized by Google

# LEGAL INTELLIGENCE.

## SIR HIRAM MAXIM ELECTRICAL AND ENGINEERING COMPANY, LIMITED.

In the Chancery Division Mr. Justice Buckley heard the case of Sir Hiram Maxim Electrical and Engineering Company, Limited—Tracy and another *v.* the company.

Counsel stated that it was a motion for the appointment of a receiver in an action brought by the debenture trustee. The company was now in liquidation, but the action was started before that event, and the official receiver had intimated that he would not object. The debenture stock amounted to £20 000, and his clients had a general charge on all the assets. The motion asked for the appointment of Mr. Alfred Hardie as receiver and manager. Counsel added that the company had a number of outstanding contracts, amounting to about £27.000, which had to be completed. The trust deed in favour of the plaintiffs was a charge on all the company's assets, including its uncalled capital.

Some question arose on the point whether the articles of association empowered to mortgage the uncalled capital, and his Lordship made an order, subject to the articles, authorising the mortgage.

## MOTOR TRACTION COMPANY.

In the Chancery Division, before Mr. Justice Buckley, Mr. Buckmaster, K.C., on behalf of the plaintiff, mentioned the case of Mason *v.* the Motor Traction Company.

Counsel stated that he had proposed to apply for an injunction restraining the company from continuing with a reconstruction scheme, but would ask for the motion to stand over, so that he could look into some accounts.

His Lordship assented to a postponement.

## EDEY v. SMITH.

This case was concluded in the City of London Court on Friday last. The action was brought by Mr. F. G. Edey, trading as F. G. Edey and Co., electrical engineers, against Mr. F. H. Smith, of Beaufort-street, Chelsea, to recover £76 for work done and materials supplied for electric lighting of certain flats. The defendant had been building flats at Chelsea, and had entrusted to the plaintiff the contract for supplying the electric lighting and electric bells. The plaintiff's case was that he had done the work satisfactorily, although he had no doubt been prevented from completing it. The defendant's case was that the plaintiff had refused to complete his contract, and that the work was done so badly that the defendant could not ask for payment for it from the Chelsea Electric Lighting Company, who were to approve of it. The electric bells which the plaintiff put up would not ring. No local authority would supply electricity to the flats in consequence of there being no fuses put in by the plaintiff.

When the case was last before the court, Judge Rentoul, K.C., gave judgment for the plaintiff for £20 on one item of the claim, and said that as to the rest the plaintiff was to complete the work. It was now stated that the defendant would not allow the plaintiff to do so, and judgment was given for the plaintiff for a further £46. 5s., with costs.

## THEFT OF ELECTRICITY.

Joseph Wallace, a miner, of Spennymoor, was charged at Auckland Police Court with fraudulently obtaining electric light belonging to the Northern Counties Electric Supply Company.

The accused inserted a pin between the flow and return wires, thus establishing a circuit independent of the meter.

Defendant was fined £1, or 14 days.

# COMPANIES' MEETINGS AND REPORTS

## NERNST ELECTRIC LIGHT.

The fifth annual meeting was held on Monday at the Westminster Palace Hotel.

**Mr. Bernard M. Drake,** in moving the adoption of the report, stated that, in accordance with resolutions passed at previous meetings, the capital had been reduced from £320 000 to £90,000. There were two alternatives open to the Board. The first was to liquidate the Company and reconstruct, which might have produced a bad impression among their customers, and the second was the course which had been adopted. A profit of £4 840 had been made during the year, against £3,926 in the former year, and a loss of £1,643 two years ago. The profit on sales of lamps and British royalties showed an increase of £1,401, which, in view of the disturbed state of some of the Company's territories, such as China, Japan, and Asia generally, where trading operations have come practically to a standstill, might be deemed satisfactory. Further agencies had been established in their different territories, the number at present being 56. It was recommended that the profit should be dealt with by placing £1,250 to a patent depreciation reserve fund and by paying a dividend at the rate of 3½ per cent., leaving £349 to be carried forward, after providing £100 to meet the alteration in the market value of investments up to Sept. 30 last. The question of the amount to be set aside for depreciation in the value of the patents had been the subject of considerable discussion, and, with the exception of one director, the Board were of opinion that, considering the wholesale way in which the book value of the patents had been written down, the figure for this year, at any rate, was all that they required to provide. The lamps as now made by the Allgemeine Gesellschaft contained many features covered by patents taken out by himself and other members of the technical staff. These patents were handed over to the Company without consideration, and were most useful to them in making the present agreement with the Allgemeine Gesellschaft. Referring to the dispute which had arisen in reference to the directors' fees, he said that his colleagues and himself placed themselves unreservedly in the hands of the shareholders as to the amount to be drawn by them in the future.

**Mr. J. G. Dalzell** seconded the adoption of the report.

Considerable discussion followed with regard to the management expenses and the directors' fees. A shareholder remarked that the Company were doing only a commission business, and he thought that a smaller office might be taken and the staff reduced. Until they commenced to manufacture lamps themselves he did not see why they should go to the expense of making a lot of experiments.

In answer to a question as to whether some reduction could not be effected in the amount of £3,025 for management expenses, the **Chairman** remarked that in their business, as in all others, there must be a definite percentage of standing charges to the turnover. There was every reason to hope that in future the percentage would decline materially, but he did not think that they would be wise to leave their present offices, which had been fitted up with testing instruments and other appliances, and go to some back garret. As to the staff, he did not know anyone with whose services they could dispense. They had one technical man who knew the whole history of the lamp, and whose knowledge would be of great value in the event of their commencing to manufacture the lamps themselves. He added that he and his partner held 6,000 shares, so that he had every inducement to try to make the Company successful.

The report was then adopted, and a resolution was passed fixing the directors' fees for the current year at £500.

**Mr. A. M. Oppenheimer** moved, and **Mr. Rushton** seconded, the election of Sir Henry Seton-Karr, M.P., in the place of Mr. Wallis-Jones. Mr. Oppenheimer said that Sir Henry Seton-Karr had promised to support his policy of retrenchment.

The **Chairman** stated that if Mr. Wallis-Jones were not re-elected he and Mr. Dalzell would leave the Board.

**Mr. G. Kitchin** strongly opposed the proposed election of Sir Henry Seton-Karr, remarking that they wanted technical men or good business men to conduct the business.

**Sir Henry Mance** observed that at present there were two solicitors on the Board, and he believed that Sir Henry Seton-Karr was a barrister. If they left the Company in the hands of legal gentlemen, he felt certain their shares would not be worth 1s. each.

The **Chairman** observed that the absent shareholders should be afforded the opportunity of considering the critical position which had arisen, and after a long discussion a resolution was carried adjourning the meeting for a month.

## CITY AND SOUTH LONDON.

The report for the half-year ended Dec. 31 last, to be submitted to the meeting on the 31st inst., states that receipts from all sources for the past half-year have amounted to £74,892, and the cost of working has been £35,369, leaving a profit of £39,523. Inclusive of the balance brought forward from June 30 last, the net revenue account shows an aggregate total of £40,224. After making provision for the debenture stock interest and the transfer to the renewal fund of £1,500, a balance remains available for dividend of £27,445. Out of this the directors recommend the full dividend of 5 per cent. per annum on the preference stocks, 1891, 1896, and 1901, and that a dividend at the rate of 1¾ per cent. per annum be paid on the consolidated ordinary stock for the half-year, leaving a balance of £1 450 to be carried forward. The number of passengers, exclusive of season-ticket holders, carried during the half-year was 8,401,846, a decline of 1.309 216. Receipts from this source (including season tickets) were £70,705, a decrease of £1,581. The decrease in traffic as compared with the corresponding period last year is attributable to the exceptionally fine and dry weather which prevailed during the greater part of the half-year, whereas the weather in the previous year was unusually wet. Arrangements with the various railway companies in respect to the Euston extension being now completed, a contract will be entered into for the construction of the extension. In providing the capital necessary for the work it is found to be more economical to issue the stocks authorised at the last meeting as part of and ranking with the other stocks of the Company and liable to dividend in the usual course, but arrangements are in progress by which the amount payable as dividend on these stocks will, it is anticipated, be met by receipts from other sources. The interchange traffic with the Great Northern and City Railway is increasing satisfactorily.

## ANGLO-AMERICAN TELEGRAPH.

After placing £10,000 to the renewal fund for the half-year, the directors recommend a balance dividend of 17s. 6d. per cent. upon the ordinary consolidated stock for the year ended Dec. 31, 1904, and a balance dividend of £1. 15s. per cent. upon the preferred stock for the year ended Dec. 31, 1904, leaving about £3,194 to be carried forward. The above dividends, together with those already paid, will amount to £2. 15s. per cent. on the ordinary consolidated stock and £5. 10s. per cent. on the preferred stock for 1904.

## NORTHAMPTON ELECTRIC LIGHT.

Resolutions have been unanimously passed by the several classes of shareholders in this Company, and also by extraordinary general meetings of the Company, whereby the rights of the shareholders have been so far modified as to extinguish on certain terms the special privileges lately attaching to the "first issue" ordinary shares, and also

Digitized by Google

converting the 6 per cent. preference shares into 5 per cent. preference shares. The result is that as from the 1st inst., and subject to certain payments to be made out of revenue, there will be only two classes of shares—namely, ordinary and 5 per cent. cumulative preference.

## DIRECT UNITED STATES CABLE.

The half-yearly meeting of this Company was held on Tuesday, when the report, of which we gave particulars last week, was adopted.

## DUBLIN UNITED TRAMWAYS.

The half-yearly meeting of this Company was held in the Sackville Hall, Dublin, on Tuesday, Mr. Wm. Murphy (chairman) presiding.

The annual report stated that the amount available for division was £50,313 0s. 9d., out of which dividends were recommended at the rate of 6 per cent. on the preference shares and 6 per cent. on the ordinary shares. The sum of £6,847. 13s. 6d. was carried forward.

The **Chairman** stated that there had been a falling off in the passenger traffic for the first half of the year, but this was only a temporary decline, and the receipts for the second half of the year showed a favourable state of affairs. The increase in parcels traffic continued. A substantial reduction in the income-tax assessment was obtained on appeal to the Commissioners.

The report was adopted unanimously.

## METROPOLITAN RAILWAY.

The dividend for the past half-year is announced at the rate of 3 per cent. per annum, as last year, but with £10,000 placed to special reserve and £11,000 carried forward. The dividend on the surplus land stock is at the rate of 2¾ per cent. per annum, being also the same as last year. The report states that the installation of the power station, Neasden, is so far completed as to enable a service of passenger trains to be run between Baker-street and Uxbridge, and the number of such trains is being gradually increased. This working was commenced on Jan. 1, and it is intended shortly to run the whole service on this section by electrically-driven trains. The work on the Inner Circle is being proceeded with rapidly, and electric traction will follow on there as soon as the equipment is finished.

## LONDON, BRIGHTON, AND SOUTH COAST RAILWAY.

The half-yearly report of this Company contains the following reference to the electrification scheme: "The Board has now decided, on the recommendation of its consulting electrical engineer, made after a long and exhaustive enquiry, to carry out a scheme of electrification on the South London Railway from Battersea Park to Peckham Rye upon a system presenting many novel features, the working of which will be watched with great care. The initial cost will not be large, and the results will be very interesting, and may have a most important bearing upon the future working of the Company's traffic."

The accounts show a balance of revenue over expenditure of £832,230.

## NEW COMPANIES REGISTERED.

**Sunbeam Motorcar Company, Limited.**—Capital, £40,000. Object: to adopt an agreement with John Marston, Limited, and to carry on the business of manufacturers of motor cycles and carriages, motors, motorcars, builders of boats and other marine vessels propelled by electricity or other power, etc.

**Stanley Electric Carriage Company, Limited.** — Capital, £10,000. Objects: to adopt an agreement with A. E. Gadd and G. Stephenson, and to carry on the business of vendors and factors of and dealers in motors, motorcars, airships, launches, cycles, velocipedes, carriages, and other vehicles (whether propelled by electricity or other power), electrical, mechanical, and general engineers, etc.

**Foreign Electrical Bleaching Patents, Limited.** — Capital, £15,000. Objects: to acquire and work the patents, rights, and other assets comprised in an agreement, dated Nov. 4, 1901, between A. A. Vogelsang and W. Lewin, for the sale of an invention of a process of electrical bleaching known as the Vogelsang Process, for all countries except England, Germany, and Austria-Hungary, and to carry on the business of bleachers. Registered office: St. Michael's House, Basinghall-street, E.C.

**Langdon-Davies Motor Company, Limited.**—Capital, £5,000. Objects: to adopt an agreement with the Langdon-Davies Motor Company, Limited, for the acquisition of certain patents and other rights and properties, and to carry on the business of suppliers and sellers of alternate-current motors, etc. Registered office: 101, Southwark-street, S.E.

### Liens Registered.

**Wirral Railways Company, Limited.**—A trust deed, dated Dec. 30, to secure £60,000 debentures created Sept. 26, 1904, has been registered. Property charged: certain freehold property and shares and the company's general assets. Trustees: T. H. Jackson, The Manor House, Birkenhead, and J. Tomlinson, M.P., Willington Hall, Cheshire. Also issue on Dec. 20 of £3,000 debentures, part of the above-mentioned series.

**Buenos Ayres New Tramways Company, Limited.**—A trust deed, dated Dec. 1, 1904, to secure £300 000 debenture stock, with power to issue further stock not exceeding £50,000, has been registered. Property charged: the company's undertaking and property, present and future, including uncalled capital. Trustees: J. G. Le Marchant, 13, Thurloe-square, S.W., and J. Head, 40, Lowndes-square, S.W.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Keighley.**—The Corporation invite tenders for tramcars. Tenders by Jan. 30.

**Halifax.**—The Corporation invite tenders for coal conveyors. Tenders by Jan. 31.

**Todmorden.**—The Corporation invite tenders for the supply of electricity meters. See advertisement.

**Saragossa (Spain).**—Tenders are invited for 32 candelabra for the municipal theatre. Tenders by Jan. 30.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Milan.**—The Mediterranean Railways require tenders for an electric crane to be erected at Gallarate. Tenders by Feb. 10.

**West Hartlepool.**—The Corporation require tenders for additional 250-kw. set, with the necessary switchboard, panel, etc.

**Arenas De San Pedro.**—The Municipality require tenders for public electric lighting for 20 years. Tenders by Feb. 12.

**Paris.**—The Colonial Office, rue Jean-Nicot 4, require tenders for 106,000 kilos galvanised telegraph wire. Tenders by Jan. 31.

**Paris.**—The Artillery Depôt, avenue de Saxe No. 2, require tenders for 370,000 kilos copper and 217,000 kilos zinc by Feb. 9.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Bucharest.**—The Government require tenders for the annual supplies to the Regie for lighting materials and accessories. Tenders by Feb. 7.

**Ilford.**—The Urban District Council invite tenders for the supply of about 2,400 yards ·4in. concentric armoured cable. Tenders by Feb. 7. See advertisement.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply of 10 complete feeder pillar boxes, with bases. Tenders by Feb. 1. See advertisement.

**Kirkcaldy.**—The Town Council invite tenders for the extension of about 500ft. in length of the present East Pier. Tenders to the Town Clerk by Feb. 4. See advertisement.

**Bury.**—The Electricity Committee invite tenders for the supply and erection of one 500-kw. direct-current high-speed generating set. Tenders by Feb. 14. See advertisement.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Vienna.**—Tenders are required for telegraph and telephone materials. Particulars may be obtained from the K. K. Post Oeconomie-Verwaltung, Vienna. Tenders by Jan. 31.

**Grimsby.**—The Corporation invite tenders for (No. 30) motors; (31) water-purifying plant; and (32) 12 months' supply of stores. Tenders for 30 and 31 by Jan. 23, those for 32 by Feb. 1.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Stockport.**—The Tramways Committee invite tenders for the overhead equipment of about four miles of electric tramway, and also for copper rail bonds. Tenders by Feb. 6. See advertisement.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Leith.**—The Corporation invite tenders for the supply and erection of one 600-kw. steam dynamo, one water-tube boiler, and one traction switchboard. Tenders to the Town Clerk by 6 p.m. on Feb. 15.

**Caen (France).**—The Prefect requires tenders for concession of a tramway from Ryes to Caen *via* Creully for goods and passengers. Particulars from the Prefect of Calvedos, Caen. Tenders by Feb. 1.

**Brussels.**—Tenders are required for erection of an electric station at the goods railway station at the port. Specification No. 391 is obtainable from the Belgian Government Railways. Tenders by Feb. 8.

**West Ham.**—The Council invite tenders for the supply of engine-room stores, cables, integrating wattmeters, double-pole house cut-out boxes, transformers, incandescent lamps, and coal. Tenders by Feb. 6. See advertisement.

**Stockton-on-Tees.**—The District Fund, Gas, Quay, and Electricity Committees invite tenders for the several articles and stores required by them for the year ending March 31, 1906. Tenders by Feb. 10. See advertisement.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Bermondsey.**—The Borough Council invite tenders for the supply of arc lamp carbons, conduits, electricity meters, demand indicators, and mains, fuses, engine oils, indiarubber cables and jointing material, lead covered cables and meter boards. Tenders to the Town Clerk by Feb 6. See advertisement.

**Christiania.**—The Government Railways require tenders for 8,000 kilos 4mm. galvanised iron wire, 5 000 kilos 3mm. ditto, 500 kilos salammoniac for Léclanche batteries, 500 carbons for ditto, and 4,000 insulators. Tenders, addressed to the office of the Administration, Jernbanetorret 8·9 in Christiania, in envelopes marked "Anbud paa Telegraf-og Telefon-materiel," to be received by Feb. 3.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative pro-

Digitized by Google

posals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**Hammersmith.**—The Council invites tenders for the supply of (*a*) arc lamp accessories; (*b*) arc lamp globes, etc.; (*c*) brooms and brushes; (*d*) carbons; (*e*) commutator brushes; (*f*) electrical goods; (*g*) files; (*h*) firebricks, clay, and lime; (*i*) gauge glasses; (*j*) incandescent lamps; (*k*) insulated wires; (*l*) lubricating oil; (*m*) metals; (*n*) meters; (*o*) oilman's goods; (*p*) packing and jointing materials; (*q*) screws; (*r*) tools; and (*s*) Welsh smokeless and other steam coal. Tenders by Feb. 8 See advertisement.

**Handsworth (near Birmingham).**—The Urban District Council invite tenders for the supply and delivery of the following in connection with the electric lighting undertaking: (Contract No. 10) power and lighting circuits and fittings in generating station; (11) pipework, feed pumps, economiser, etc.; (12) electricity meters. Tenders will only be considered for the whole of the work covered by each specification, and not for any part thereof. Copies of the specification, with the conditions of contract, etc., can be obtained from Mr. H. Ward, clerk. Tenders to the Clerk before noon on Feb. 2.

**Melbourne.**—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess, M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

## RESULTS OF TENDERS.

**Falkirk.**—The Town Council have agreed to accept the offer of the General Electric Company, Limited, for the supply of lamps.

**London, E.**—The Whitechapel Guardians have accepted the tender of Cunningham and Co., of Edgware-road, for the installation of electric light at Section 2 of the infirmary.

**Belfast.**—The Corporation have accepted the tender of the Forest City Electric Company, 3, Gore-street, Piccadilly, Manchester, for protected rail bonds for the Leith and Belfast Corporation tramways.

**Oban.**—The Town Council have decided to accept the tender of J. Venner and Co. for the supply of meters for the ensuing 12 months—viz.: 1½ amperes, £1. 12s. 6d. each; 3 amperes, £2. 1s. each; 5 amperes, £2. 3s. 6d. each; 10 amperes, £2. 10s. each; 25 amperes, £2. 15s. each; 50 amperes, £3 each; 100 amperes, £3. 5s. each.

**Erith.**—The Urban District Council have accepted the tender of the British Westinghouse Electrical and Manufacturing Company, Limited, Norfolk-street, Strand, W.C., for 14 Brush car bodies, Mountain and Gibson trucks, own equipments, and seven Brush top-deck covers, at £8 522. 5s; magnetic track slipper brakes, at £700; and a track sweeping and watering car, at £626. 10s.

**Fulham.**—The following tenders have been received for the supply and erection of a 1,000-kw. alternator—viz.:

| | |
|---|---|
| General Electric Company (accepted) | £6 718 |
| Witting, Eborall, and Co. | 6,891 |
| Siemens Electrical Company | 6 894 |
| Mather and Platt | 6 910 |
| Bruce Peebles and Co. | 6,935 |
| J. Fowler and Co. (Leeds) | 6,935 |
| International Electric Company | 6 935 |
| British Thomson-Houston Company | 7,003 |
| Dick, Kerr, and Co. | 7 090 |
| Electric Construction Company | 7 135 |
| Westinghouse Electric and Manufacturing Company | 7.197 |
| Westinghouse Electric and Manufacturing Company (alternative) | 7.357 |
| Electrical Company | 7,535 |
| Vicars, Son, and Maxim | 7,545 |
| Brush Electric Manufacturing Company | 7,555 |

**Bradford.**—The Education Committee have accepted the tender of Messrs. Roberts Bros., 15 and 17, Lee-street, Thornton road, Bradford, for the lighting of the Dudley-hill new Council Schools by electricity.

**Dover.**—The British Electric Equipment Company, Limited, 11, Queen Victoria-street, E.C., have obtained the contract for the construction of the permanent way, overhead equipment, and laying of cables in connection with the Dover and River light railways.

**London.**—The Metropolitan Asylums Board have received the following tenders for extending telephone system, etc., at the North-Western Hospital:

| | | | |
|---|---|---|---|
| J. W. Gray and Son (accepted) | £126 | 10 | 0 |
| Private Wire and Telephone Installation Company, Limited | 140 | 0 | 0 |
| New System Private Telephone Company, Limited | 160 | 13 | 4 |
| A. V. Gifkins and Co. | 162 | 0 | 0 |
| Buchanan and Curwen | 168 | 0 | 0 |
| J. Richmond and Co. | 258 | 10 | 0 |

And for the installation of electric light, telephones, and fire alarms in a portion of the Belmont Asylum:

| | | | |
|---|---|---|---|
| Bromley and Batstone, 24-26, Holborn, E.C. (accepted) | £2,244 | 0 | 0 |
| F. A. Glover and Co., Limited, Vine-street, Clerkenwell-road, E.C. | 2,483 | 10 | 0 |
| Belshaw and Co., 53, Victoria-street, S.W. | 2,660 | 0 | 0 |
| Buchanan and Curwen, 64, Victoria-street, S.W. | 2,675 | 0 | 0 |
| Wenham and Waters, Limited, Croydon | 2,806 | 0 | 0 |
| Bergtheil and Young, Limited, 12, Camomile-street, E.C. | 3,176 | 10 | 0 |

# BUSINESS NOTES.

## TRACTION.

**Bradford.**—The Corporation will shortly issue a tramway time-table.

**Wolverhampton.**—It is reported that the Hunter-street route was opened on Monday.

**Dolter System.**—An exhibition of the Dolter surface-contact system was given at the Grand Hotel, Birmingham, on Monday.

**Underground Electric Railways Co.**—The London County Council have approved amended plans for Piccadilly-circus Station.

**Perth.**—A start has been made with the reconstruction of the tramway system, which it is hoped to complete in three or four months.

**Glasgow.**—The Corporation tramways have attained a record for their weekly receipts, the total being £17,069, against £16,040 in June last.

**London United Tramways Co.**—The Kingston Town Council have approved the plans submitted by the company for new tram routes, subject to one or two amendments.

**Falkland.**—At a meeting of the committee of the Fife County Council it was decided to form a local committee to make all the preliminary arrangements for the tramway scheme.

**Cardiff.**—Considerable alterations are about to take place in the tramway service, the result of which will be that certain routes will be abandoned and other routes will have a more regular service.

**Swansea.**—A satisfactory trial trip has been run on the Morriston section. It is not thought, however, that the Board of Trade will inspect this small section of the line before the others are ready.

**Baker-street and Waterloo Railway.**—The St. Marylebone Borough Council have decided to oppose this company's Bill, which provides for the construction of four new subways in the borough.

**Belfast.**—The contract with Messrs. J. G. White and Co. for the electrification of the tramways was completed last week, and it is reported that a commencement was to be made with the work on Monday.

**Dalkeith.**—The authorities are reported to be favourably disposed towards the electric tramway scheme referred to in our last week's issue, and it is stated that the line will ultimately be extended to several of the surrounding districts.

**Swindon.**—Since the opening of the trams on Sept. 22 the total number of passengers carried up to the 28th ult. was 674,474. The receipts amounted to £2,627. 7s. 9½d., while it is estimated that the total expenses will be £150 per week.

**Shoreditch.**—It is reported that the Borough Council have decided to propose that petrol or other power motors should be adopted for the trams within their district, so as to dispose of the question in regard to the type of electrical system.

**Central London Railway Co.**—The directors declare the following dividends: on the undivided ordinary and preferred stocks, 4 per cent. for the half-year; on the deferred stock, 4 per cent. for the whole year, £30,000 being carried to reserve and £22,000 forward.

**Lancashire and Yorkshire Railway Co.**—The dividend for the half-year ended Dec. 31 is announced at the rate of 3¾ per cent. per annum, as compared with 3½ per cent. per annum for the second half of 1903, carrying forward a balance of £31,000, as against £32,800

**Cheap Labour.**—We are informed that a mass meeting of electrical workers and others is to be held in the White Hart Hotel, Acton, W., on Feb. 2, at 8 p.m., to protest against the employment of cheap labour upon the electrification of the District and other underground railways of London.

**Greenock.**—In the arbitration case between the Greenock Corporation and the tramways company it is reported that the Board of Trade have awarded £602. 18s. 9d. as the proportion of profits due to

Digitized by Google

the Corporation, while the company are to account for two sums of £75 set aside for maintenance and £1,500 placed to depreciation.

**Tube Railways.**—The Law and Parliamentary Committee of the Fulham Borough Council have prepared a lengthy list of recommendations for the protection of the borough's interests in connection with the Central London, the Hammersmith, City and North East London, and the Great Northern, Piccadilly, and Brompton Railways.

**Llanelly.**—At last week's meeting of the Town Council the chairman stated that he and the town clerk had gone into the draft agreement with the traction company very carefully. So far as the legal position was concerned, he believed that every point had been covered. After taking the advice of an electrical expert the agreement is to be submitted to a special meeting.

**Gainsborough.**—At the monthly meeting of the Urban District Council, Messrs. Harrison, Beaumont, and Smith, of Wakefield, wrote in connection with the Ackworth and Lindsey Light Railway that their clients' proposal was to carry a tunnel underneath the River Trent, and in no way to interfere with the navigation. The Council considered this reply satisfactory.

**Private Bills.**—The Examiners of the House of Commons have passed the following measures as complying with Standing Orders: Central London Railway (New Lines); Blackpool, St. Annes, and Lytham Tramways; Tyneside Tramways and Tramroads Company; North-East London Railway; Shropshire and Worcestershire Electric Power; and the Metropolitan District Railway.

**Exeter.**—The Tramways Committee have received a communication from the contractors, Messrs. Dick, Kerr, and Co., stating that they will be pleased to undertake the construction of the tramways through Heavitree at scheduled rates and under the same conditions as those obtaining for their present contract. The committee recommend that the work in Heavitree be now proceeded with.

**Kirkcaldy.**—The Kirkcaldy and Dysart Water Commissioners and Wemyss Parish Water Committee have had the tramway scheme under consideration in regard to the possibilities of it injuring their pipes. A request has been made for special protective clauses wider in scope than those given under the statute. It is, hoped, however, that the matter will be arranged so as to avoid opposition to the provisional order.

**Southend.**—At last week's meeting of the Town Council it was reported that the expenditure on the light railways for the current financial year would considerably exceed the estimate. Councillor Roberts stated that the matter was being carefully investigated, and that full particulars would be laid before the Council. A proposition to revert to the system of running the cars over the beach section was negatived after a close vote.

**Liverpool Overhead Railway Co.**—The accounts of this company for the past half-year show an available balance of £10,134. 18s. 6d., and the directors have resolved to recommend payment of a dividend at the rate of 5 per cent. per annum on the preference shares and 1½ per cent. per annum on the ordinary shares, against 1½ per cent. per annum on the ordinary shares for the corresponding period last year. Balance carried forward, £3,743 against £4,132.

**Through Running.**—Replying to our circular letter of Nov. 29, Mr. J. Lyon Whittle, the town clerk of Warrington, who has been unable to answer earlier, writes that his Corporation have recently been approached by the promoters of the Northwich light railway, and have conceded the principle of interchange of traffic, subject to terms to be mutually agreed upon. Mr. Whittle adds that the subject is one of great difficulty, but, in his opinion, is capable of satisfactory adjustment.

**Walsall.**—The report of the first year's working of the municipal trams has just been issued, and shows a gratifying result. This is made up to the end of 1904, and a net profit of £2 270 appears, after payment of all charges, including interest and sinking fund. The Tramways Committee strongly recommend that this surplus should be carried to a reserve fund, as they believe it will be a sound policy to build up such a fund to the maximum amount allowed by the Walsall Corporation Act.

**East London Railway.**—The report for the half-year ended Dec. 31 states that, anticipating the electrification of the Metropolitan and the Metropolitan District Railways, and the consequent suspension of their through train services over the line, a temporary scheme for future working and schedules of new train services have been agreed. Relative plans for cross-over roads and signals, and for facilitating the interchange of passengers with these railways at Whitechapel Station, have also been passed.

**Hastings.**—The Corporation have decided to formally lodge a petition against the company's Bill, referred to in previous issues. Councillor Gray, in moving the adoption of this course, remarked that it need not be any barrier to a conference between the parties on outstanding questions. At a meeting of the Bexhill Corporation a deputation from the company was received in reference to the route proposed for this section of the system. The promoters now contemplate a line to the centre of Bexhill only, deferring the construction of the line to Kewhurst. The Corporation decided that they could not assent to the company's Bill in its present form.

**Erith.**—At last week's meeting of the Urban District Council the consulting engineers, Messrs. Hawtayne and Zeden, submitted a report stating that the contractors had made fair progress with the permanent way. In the Bexley-road the track had been completed down to the double line near the bridge, where a short stoppage had to be made for the removal of gas and water mains. A letter was read from the Board of Trade provisionally approving of the system of electric traction proposed to be adopted, subject to any requirements which may be considered necessary on the inspection of the completed works.

**Mont Blanc Railway.**—M. Duportal, the author of the system accepted for running a tramway line up Mont Blanc, on the Chamounix side, has given some interesting details of the work, which has already been put in hand. Steel rails are being used, and each will rest upon 12 metallic sleepers or traverses. The trams will consist of an electric locomotive, a coupled car, and a trailer, capable of holding 80 persons. The speed on horizontal planes will be about 4½ miles an hour, and on vertical planes 1,236 yards an hour, with numerous stops, to enable passengers to enjoy the points of view and to gradually "acclimatise" them against mountain sickness. The journey will last four hours, and will cost 32s. 6d.

**The Municipal Tramways Association.**—At a meeting of the Sunderland Tramways Committee a letter was read from the Municipal Tramways Association calling attention to the fact that Bills were being promoted by the Midland, North-Eastern, and Great Western Railway Companies to enable them "to own, work, and use in any district, or to or from any place served by the companies' railways, omnibuses, coaches, cars, or other road vehicles to be drawn by animals, electrical, or any mechanical power, and therein to carry passengers, luggage, parcels, merchandise, etc." The committee decided to support the Municipal Tramways Association in an enquiry as to what was to be done in the matter.

**Aberdeen.**—The question of the renewal of the Aberdeen Suburban Tramway Company's lease for running powers over the Corporation system was under consideration at the meeting of the Tramways Committee. The committee considered that before any decision was come to it would be advisable to obtain certain information as to the facilities given in English towns by the corporation to suburban companies, and it was therefore agreed to defer the matter, and to call a special meeting on an early date to discuss the whole subject. One special point for consideration will be the recent decision of Lord Balfour, the arbiter between Glasgow and Paisley, where the arrangement is very much similar to that at present obtaining in Aberdeen.

**Huddersfield.**—The revenue account for the nine months ending Dec. 31, 1904, shows that the miles run numbered 1,272,682, as against 1,237,763 last year. The receipts amount to £54,095. 9s. 2d., representing 10·20d. per car mile, as compared with 9·83d. per car mile in the corresponding period last year. On the expenditure side £6,494 was the figure for maintenance and repairs (1·23d. per car mile, as against 1·01d. last year); £2,493 for generation of electricity (at the rate of ·47d. per car mile, the same as in the previous year); £12,521 for traffic expenses (2·36d. per car mile, as against 2·58d. last year). The total working expenditure was £27,422 (5·17d. per car mile, as against 5·29d. last year), leaving a gross surplus of £26,672 (5·03d. per car mile, as against 4·54d. last year). Of this amount £9,824 went as interest on debt, and £7,991 for redemption of debt, making a total of £17,815 (or 3·36d. per car mile, as compared with 3·78d. last year). The surplus, without making any allowance for depreciation, amounts to £8,857 (or 1·67d. per car mile, as compared with ·76d. per car mile last year).

**London County Council.**—The Board of Trade have given their approval to the conduit system, including an increase in the width of the slot from ⅜in. to 1in., for the reconstruction of the first sections of the Council's northern system. At Tuesday's meeting of the Council the Highways Committee reported that, owing to the assiduity of the tramway staff, the services had been well maintained during the foggy weather experienced recently. The receipts for the five weeks ending the 14th inst. totalled £61,923, against £46,268 last year, and from April 1 £526,542, against £410,000. The Council decided without discussion to abandon the suggested acquisition of Charing Cross railway station and of Hungerford Bridge for the purpose of carrying the tramways across the Thames. The Chairman of the Highways Committee stated, in reply to questions, that the covered tramcars earned on the average 1½d. per car mile more than the other cars, representing a difference per car of about £4 per week. Tramway fares to the amount of 1d. or ½d. can now be paid on the London County Council's system by celluloid discs, which are to be obtained in quantities of not less than 5s. in value.

**London Traffic Commission.**—At a conference between the Chairmen of Committees of Lords and Commons and the parliamentary agents, Lord Balfour announced, with reference to the intimation of the Board of Trade that the London tube schemes would not be taken until the report of the London Traffic Commission was presented to Parliament, that the Committees did not feel inclined to decide what would be done with those schemes until Parliament had had an opportunity of considering the report. The London Traffic Commissioners will meet on Thursday, Feb. 2, to further consider their report, but it is not anticipated that the report will be placed in the hands of the Government before the end of March. The Parliamentary Committee of the Westminster City Council recommend that, pending the finding of the Royal Commission on London Traffic, it is necessary for the Council to secure a right to be heard against any Bill proposing to construct a new railway which does not contain adequate protective clauses. The committee's report referred to the Waterloo Railway Bill; the Charing Cross, Euston, and Hampstead Railway Bill; the Central London Railway (New Lines) Bill; the Great Northern, Piccadilly, and Brompton Railway Bills (Nos. 1 and 2); the Hammersmith, City, and the North East London Railway Bill.

**Rhondda.**—At the adjourned public meeting held to consider the Bill which the Urban District Council propose to promote, the clerk explained in regard to the tramways that the Council was not going to pledge the rates to the extent of a single penny. The scheme provided for the leasing of the tramways to a company for a period of 42 years. On their part the company undertook to equip and complete the tramways to the satisfaction of an engineer to be appointed by the Council. It was not obligatory upon the company to carry out any street widenings, neither was it obligatory on the part of the Council to do so. The total rental paid by the company would be £2,250 per annum. The lease would contain a clause that in the event of failure on the part of the company to carry out any of the

Digitized by Google

provisions of the lease, the Council would be in a position to determine the lease after giving three months' notice, at the expiration of which, if the company failed to remedy any breach, the Council would be entitled to take possession without paying any compensation whatsoever. The Council would have precedence over all debenture holders on the undertaking. At the expiration of 42 years the Council could purchase the tramways at an amount to be fixed by agreement or by arbitration, or re-lease the tramways for another period of 21 years. The lessors would have to keep the tramway for 42 years, otherwise the Council would enter into possession without the payment of any compensation whatsoever. The company would have to deposit £10 000 with the Council as security for the due performance of the agreement entered into. Eventually the Bill was approved.

**Halifax.**—A Gilbertian situation has been occasioned by the refusal, as represented by a meeting in the Mechanics' Hall, to endorse one section of the Corporation's parliamentary Bill. The Council, under powers previously obtained, have partly constructed a tramline on the flat from Salterhebble Hill towards West Vale. Under their present Bill they desired authority to connect this up with the existing tramway at Salterhebble. Why parliamentary authority to do this was not previously sought is explained by the fact that at that time the Corporation intended continuing the Salterhebble line to West Vale *via* a proposed "lift" tramway at the Dudwell-lane steep. Under this scheme, somewhat after the fashion of the Scarborough cliff tramways, the cars were to descend or ascend on a platform carriage and be deposited on the connecting metals to resume their journey. The opposition brought to bear against this scheme on the ground of the uncertainty as to its safety caused it to be abandoned. The Corporation, on their part, claimed that there would be less risk attached to it than would be involved in the adoption of the alternative scheme of providing a connection *via* the steep and curving route of Salterhebble Hill. With this latter scheme now also condemned by the ratepayers the Town Council are in the dilemma that they have a length of line constructed in the Valley-road with the only possible method of connection left them eliminated from their Bill. There is a feeling among some members that there should be an appeal from the limited body of ratepayers gathered at the Mechanics' Hall by a poll being taken of the ratepayers generally. Should this appeal be made the ratepayers will probably be asked to reverse, in addition, the amendment rejecting the intended tramway extension from West Vale to Elland.

## LIGHTING AND GENERAL.

**Southend.**—An extension of street-lighting by arc lamps at a cost of £128 has been agreed to.

**Bexhill.**—Sanction has been received for the borrowing of £3,400 for electric supply purposes.

**Blackpool.**—The electrical engineer has been asked to report upon the charges for current made to private consumers.

**Rochdale.**—An enquiry has been held into the application of the Corporation for sanction to borrow £42,500 for electric supply extensions.

**St. Marylebone.**—The Council will join the other boroughs in their opposition to the various proposed Bills which relate to the supply of electricity to the borough.

**Cardiff.**—Up to the present the Post Office telephone exchange is situated at the docks branch post office, and arrangements are now being made to transfer it to the head office.

**Coventry.**—The Corporation have experienced in the last three years an increasing demand for electric motors. Three years ago the extent of those in use was under 100 h.p.; now it is over 1 000 h.p.

**Buxton.**—The Urban District Council have decided to charge 5 per cent. for the engineer's services in cases where he is asked to specify and superintend wiring of premises, if it is agreed that he should do so.

**Swansea.**—It was stated at the last Town Council meeting that unless electric light was installed at the market the Corporation could not hope to get the £4,000 a year from the market plus interest that the late lessee used to pay.

**Wakefield.**—At the meeting of the City Council on Tuesday next it will be proposed that application be made for sanction to borrow a further sum of £18,000 for the purposes of extensions in connection with the electricity undertaking.

**Electrical Exhibition.**—The County of London Electric Supply Company announce that an electrical exhibition will be held at 118 to 122, Holborn, E.C., from March 20 to April 5, both days inclusive. Full particulars appear in another column.

**Hammersmith.**—The premises of six additional consumers, representing a maximum of 67 8 c.p. lamps, have been connected to the mains; five consumers have been disconnected. The present number of consumers taking current from the mains is 1,534.

**Westminster Electric Supply Co.**—The directors recommend, subject to audit, a dividend at the rate of 15 per cent. per annum (less income tax) for the half-year ended Dec. 31, payable on March 1 next, making, with the interim dividend already paid, 14 per cent. for the year.

**Bridlington.**—At Wednesday's meeting of the Town Council Councillor J. V. Mainprize said that within a few days it is hoped that electricity will be supplied to private consumers. It was decided to give notice to the gas company to terminate the public lighting contract.

**Hastings.**—At their last meeting the Town Council threw out a recommendation by a committee, who advised that consent be given to the Postmaster-General to place an overground telegraph line along certain streets, on condition that the poles used are painted green and repainted that colour once in every three years.

**Hampstead.**—The Borough Council have decided to lay mains for the supply of electric current in Fordwych-road and in Elsworthy-terrace, and, in order to provide for the probable additional demand for electric current during next winter, to purchase seven transformers and supply new feeders and additional distributors in various roads, at a total cost of £1,348.

**Chertsey.**—The Rural District Council have assented to the Woking Electric Supply Company's extension provisional order, from which Chobham district will be eliminated. The Chertsey Urban District Council have passed a resolution approving of the application of the Woking Electric Supply Company to extend their provisional order to the urban district of Chertsey.

**New Branch.**—We are informed that the Union Electric Company, Limited, 151, Queen Victoria-street, E.C., have decided, in view of the increased demand for their dynamos, motors, arc lamps, meters, and switchgear in the Tyne, Wear, and Tees districts, to open an office at 43, Grainger-street, Newcastle-on-Tyne. This office will be under the direction of Mr. James Gilman.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Commercial Cable Company's further issue of £29,000 sterling 500 year 4 per cent. debenture stock (redeemable); Edmundson's Electricity Corporation's further issue of 10 000 6 per cent. cumulative preference shares of £5 each, fully paid, Nos. 70,001 to 80,000.

**Brighton.**—An underground cable is to be laid from the Hove borough boundary in Lansdowne-road to the Holland-road church, at an estimated cost of £182. 13s. 9d. Mr. Wright is retiring as consulting engineer and manager of the Corporation electricity department on April 19, 1905. The amended draft agreement for the supply of electricity to the parish of Aldrington has been approved.

**Launceston.**—At the last Town Council meeting a letter was read from the manager of the Electric Supply Corporation stating that the work at Launceston had not been lost sight of, but the work they had already in hand in other towns called for immediate attention. He was not able to fix a date for the commencement of their work in Launceston, but he hoped to see it in full swing within the next 12 months.

**London Gazette.**—A first and final dividend of 8½d. in the £ has been declared in the estate of Charles Manners Downie, electrical engineer, 4, Bloomsbury-street, London, and Heathville-road, Crouch Hill, Middlesex. A notice appears of intention to transfer the undertaking authorised by the Runcorn Electric Lighting Order, 1899, to the Mersey Electric Supply Company, Limited, Central Buildings, North John-street, Liverpool.

**Catalogues—How and Where to Place Them Abroad.**—There can be no more important question to the British manufacturer than the effective placing of his catalogues abroad—without unnecessary waste or expense. Some assistance to manufacturers on this point has long been needed, and we are glad to see that a system has been organised by Messrs. Pitt and Scott, Limited, 25, Cannon-street, London, E.C., who will send their explanatory booklet free on application.

**Arbroath.**—The Council have obtained from the Board of Trade delay of three months. It will be remembered that recently the Board of Trade intimated to the Council that it was their intention to revoke the order forthwith. Their reason was the delay between the Council and an electric light and power company in arriving at a settlement with a view to the company purchasing the provisional order obtained by the Council some years ago and proceeding with the installation of the electric light in Arbroath.

**Nynehead.**—The electric light has been installed in the parish church and approaches, and the change from the old form of lighting by candle is appreciated by all. What is more, this up-to-date form of lighting has in no way interfered with the charm of the interior of the church—one of the prettiest and most interesting for miles around—for the old candelabra have been fitted with sockets filled with porcelain candles with flame-shaped frosted bulbs. At first sight the fittings might be taken for ordinary candles, and when the light is on the effect is very pleasing. Altogether there are 72 5-c.p lamps. Messrs. Stansell and Son, Taunton, were the contractors.

**Durham Collieries.**—The Sunderland District Electric Tramways Limited, have arranged a contract for the supply of power to the important collieries in the county of Durham belonging to the Lambton Collieries, Limited, managed by Sir James Joicey, Bart., M.P., with Mr. A Kirkup as chief mining engineer. It is proposed to use the power for hauling, pumping, coal-cutting, lighting, and winding purposes, as well as for the engine works at Philadelphia, which will make these collieries one of the most up-to-date groups in the country. It is proposed to erect a large central power station on five acres of land at Philadelphia, from which the power will be taken to the collieries, and, in addition, the tramways, of which over 12 miles are fully completed, will be supplied with the necessary power, as well as the supply of power for electric lighting in the urban districts of Houghton-le-Spring and Hetton-le-Hole, and the rural district of Easington, over which the company has statutory lighting powers. Power will be available at a cheap rate for other collieries in these districts, as well as for manufactories, breweries, and other works. The power station will be close to the pit's mouth, and the coal will thus be obtained a cheap rate, enabling the power to be produced under the most advantageous conditions, and at a minimum cost to the consumer. This contract has been arranged by Messrs. Harper Bros., the consulting engineers, London. An immediate start is to be made with the construction of the power station.

**Finchley.**—A letter from the West Finchley Ratepayers' Association, containing a copy of the following resolution passed at the last meeting of the association—"That in the opinion of this association it

Digitized by Google

is very desirable that the books and accounts of the Electricity Committee be audited under the supervision of or by a duly qualified accountant"—has been referred to the Finance Committee of the Urban District Council.

**Huddersfield.**—The borough electrical engineer's last report shows that there was an increase of 21 consumers at the beginning of this month as compared with December, and an increase of 159 as compared with the number at the beginning of January, 1904. At the beginning of this month 140,161 lamps had been connected, as compared with 1,133 in December last, and an increase of 7,579 as compared with the number at the commencement of 1904.

**London County Council.**—On Tuesday it was agreed to lend the Stepney Borough Council £10,000 for electric light installation. Sanction was also given to the borrowing by the St. Pancras Borough Council of £5,370 for electric light installation. Applications by Mr. A. Roberts on behalf of the Chelsea Electricity Supply Company, Limited, for the construction of a generating station, and from various metropolitan electric supply companies to lay mains, etc., were agreed to.

**Erith.**—With regard to the Bills of the Administrative County of London and District Electric Power Company and the City of London Electric Lighting Company, Limited, to be promoted in the next session of Parliament, it has been decided that in the first instance Sir William Hart-Dyke, Bart., M.P., be asked to oppose the Bills in Parliament, and that the clerk ascertain from the neighbouring local authorities what action is proposed to be taken to further oppose the Bills.

**Mexico.**—The following applications are reported: by Señor Julio Jaume for the appropriation, for irrigation, and for industrial purposes, of 3,060 litres of water per second from the River Tambaque, State of San Luis Potosi; by Señor Pedro Diaz Barreiro for the appropriation, for irrigation, and for industrial purposes, of 1,500 litres of water per second from the River Atoyac, State of Puebla; and by Señor Ituarte for the appropriation, for industrial purposes, of 1,500 litres of water per second from the Rivers Monte Alto and Los Tachos, State of Mexico.

**Spennymoor.**—The North-Eastern Railway Company receive their current from the generating station of the Northern Counties Electricity Supply at Spennymoor, and which is in close proximity to the railway station. The electric light has been installed at the railway station and its signal boxes for some time, and has proved successful. In consequence, cables have been laid along the line for a distance of about a mile from the station, and four signal cabins have been equipped, and a large number of signal lamps along the main line and the sidings have been converted into electric lamps.

**Kettering.**—The electrical engineer's report for December contains the following figures: Total applications to Dec. 31, 129; total consumers connected to Dec. 31, 123; number of consumers connected during month, 14; number of 8-c.p. lamps or their equivalent connected during month, 855; total number of 8-c.p. lamps or their equivalent connected to Dec. 31, 1904, 8,030; total brake horse-power in motors connected to Dec. 31, 1904, 100; total units generated during month, 22,614; coal consumed, 49 tons 6 cwt.; estimated quantity of coal saved by refuse destructor during month, 71 tons 3 cwt.

**New Shipbuilding Yard.**—The City Council of Sydney, Nova Scotia, will, it is anticipated, this week decide upon a grant of 250,000dol. towards the construction of a steel shipbuilding yard at the port. The Government have already decided to contribute 100,000dol. to that purpose, and as soon as the city grant becomes a fact, a company, of which Mr. J. A. Burchell is the president and Mr. W. Hayes, Sydney, N.S., is the secretary, will call for contracts for plant sufficient for the complete construction of one 15,000-ton steamer per year. The company will also build a floating dry dock to accommodate 8 000-ton steamers, and they will keep a wrecking steamer stationed at the port.

**Burnley.**—The borough electrical engineer (Mr. Birkett) and two of his staff were very severely damaged by 500-volt shocks on Friday last. Some trials of an electrically-driven air-compressor were being made before the Electricity Committee, and an accidental contact between the metalwork of this compressor and the tramway voltage was made, which metal caused the accident in question. The Guardians propose to apply for sanction to borrow £1,100, to be repaid in 15 years, to defray expenses in connection with electric light station, water-tank, and improved works of water supply to the workhouse—namely, electric lighting works, £567, being excess of expenditure over amount (£8,806) previously sanctioned.

**Thames Conservancy.**—The Parliamentary Committee have reported on a number of Bills which have been deposited for the ensuing session of Parliament, including that promoted by the City of London Electric Lighting Company for an extension of powers. By this Bill power is sought to supply electrical energy to certain riverside portions of the counties of London and Kent. Clause 2 provides that the provisions of Section 14 of the schedule to the Electric Lighting (Clauses) Act, 1899, shall apply to the laying down and placing of any cables or other works in, through, under, along, or across the bed and foreshore of any river. Clauses 16 and 17 provide that any cables, pipes, or wires under or across any tidal water shall be placed at such depth or height as the Board of Trade may require, and that any works below high-water mark shall not be commenced without the consent of the Board of Trade. In consequence application will be made to the promoters of the Bill for an undertaking to make the amendments required by the Conservators. In the event of the same not being given, a petition is to be presented against the Bill.

**Shoreditch.**—The Lighting Committee have reported that in their opinion it is necessary to instal additional plant at Whiston-street, where there is a vacant space for both boilers and engines, and that in view of the period which must elapse between the time when the extensions were approved and the time when the plant was installed and set to work, specifications should be prepared and tenders invited for the following alternative schemes: two steam turbo-generators, each of 1,000 kw. capacity, with all necessary condensers, pumps, boilers, superheater, steam and water pipes, switchgear, balancer, and underground mains, at an estimated cost of £37,000; two steam turbo-generators, each of 1,500 kw. capacity, with all necessary plant and necessaries as in scheme A, at an estimated cost of £46,000. The committee, with a view to having the fullest information in reference to the type of engine it is proposed to adopt, especially as regards the avoidance of vibration nuisance, suggested that they should be authorised to visit three of the principal stations in the country where steam turbo-generators have been in use for some time. The report was adopted at the last Council meeting.

**Spain.**—Señor D. Emilio Rodiequez has obtained a concession to take from Segre river, in the province of Lerida, water giving 4,356 h.p. Similar grants have been obtained by D. Iquacio Coll y Portabella and D. Julio Bielsa y Permu, of Barcelona; D. Julian Bosque and D. Antonio Ferrer, of Ollana, Lerida; and D. Miodesto Chillido, Toledo. Other applications are before the Government—viz., by D. Augustin Iza, of Bilbao; D. Juan Ayastuay, Vergarra; D. Victor Peadera y Larmube, San Sebastian; and D. Iquacio Romano y Suari, of Barcelona, who propose to derive electric power from various rivers. It is proposed to form an electric supply company at Navia, with a capital of 190,000 pesetas, to exploit a similar concession obtained by D. Mariano Luino, and to light La Caridad, Valdepares, El Franco, Salave, Tapia, Serantes, Barros, Figueras, Castropol y Vega de Ribadeo. The Hydro-Electric Company of Pindo at Coruna has now started two works, one for the manufacture of carburate of calcium and one for generating electric power. The current is transmitted from the latter to the former by a high-tension cable at a voltage of 10,000.

**Battersea.**—The Council have adopted a report with reference to the extension plant required at the central electric generating station to deal with the demand for the supply of electrical energy in the winter of 1905-6 stating that the electrical engineer has advised them that the plant at present installed at the station is capable of dealing with 1 990 kw. (the maximum load on the station this winter amounted to 1,400 kw.), and that it is probable that the demand for next winter will easily reach 2 000 kw. It is, therefore, essential that orders for the following additional plant and for the execution of the following works should be given without delay, so as to provide a sufficient reserve of plant, as in the event of a breakdown in one of the larger machines at the station great difficulty would be experienced in keeping up the pressure: one 750 kw. turbo-generator, £4 700; condenser with valves, £225; three watertube boilers with fittings, automatic stokers, including brickwork, £3,850; pipework in connection with turbo, boilers, and condenser, £1,400; two switchboard panels for feeders and generators, instruments, etc., £300; meter for generator, £25; cables for generator, £86; one motor-driven pump for condensing water, including pipes, starting switch, etc., £1.300; one boiler-feed pump, £150; valves for main steam line, £200; foundations for turbo and pump, to be carried out by Works Department, and chequer plating, £400; one Green's economiser with brickwork, £650; contingencies, £472; alteration to pipes in river, £1,500; office charges, £742. We understand that the necessary plant is to be procured and the necessary works carried out at an estimated cost of £16,000, and also that additional feeder cable, etc., be provided at an estimated cost of £2,100. Mr. W. Rines has been appointed one of the representatives of the Council upon the executive committee of the conference (the Law and Parliamentary Committee are to nominate the other representative) dealing with the opposition of private Electricity Bills affecting London areas. It has been referred to the executive committee to consider the advisability of inviting the co-operation of authorities outside the county of London affected by these Bills.

**Handsworth.**—A generating station is being constructed on a site adjoining Soho-road Station. A considerable length of mains has already been laid, and it is anticipated that the whole electric supply scheme will be in full working order by Midsummer. Dr. A. B. W. Kennedy is the Council's consulting electrical engineer. Handsworth is a very scattered district, and on this account the cost in regard to mains will be rather higher than in many places. It has an area of 3,647 acres, with a population of over 60,000, and stretches from Hockley Brook to the boundary of West Bromwich. The Council will, as soon as they are in a position to do so, light the main arteries of the district by electricity. The scale of charges for private consumers has not yet been settled. The length of tramway between the New Inns and the boundary of West Bromwich belongs to the urban authority, who have leased it to the tramway company. This line has already been electrified by the Council, and by the terms of the lease the Council have the option to supply current to the company. The Birchfield-road steam tramway system will shortly belong to the Council, and the electrification of this route will be only a matter of time. The Council have secured an excellent central site in Piers-road. A railway siding has been made to join the loop line from Soho Station to the Soho Pool goods station, so that coal can be conveyed straight into the bunkers at the works. The total cost of the undertaking will be about £45,000. The generating station will contain a large engine-room and boiler-house, a battery-room, stores, general offices, and workmen's rooms. The coal bunkers and the boilers will be in the lower level. The first floor will contain a meter-room, drawing office, committee-room, bath and lavatories, and spare rooms. There will be two ventilating towers and a stack 150ft. high. The system of supply to be adopted is the continuous-current three-wire system, with lamps working at about 240 volts. The dynamos will be driven direct by steam-engines, and a battery of accumulators will be provided for the purpose of supplying energy during the night time and at other periods of light load. Orders have been placed for 120 arc lamps, the standards of which will be placed 66 yards apart.

## PROVISIONAL PATENTS, 1905.

JAN. 9.

**330. An improved insulated roller contact block for electrical traction.** William Ainsley, 2, Atherton-street, Durham.

**331. Method of and means for electrically lighting-up street and other gas-lamps whose burners are beyond reach of hand.** William Pare, 11, Burlington-chambers, New-street, Birmingham.

**392. Improvements in controlling the luminosity of electric lamps and their consumption of electric current.** Frances Alice Hunter, Rockcliff Hall, near Flint, N. Wales.

**400. Improvements in means or apparatus for controlling electric and other circuits.** George Harrison, 11, Southampton-buildings, Chancery-lane, London. (The Albert and J M. Anderson Manufacturing Company, United States.) (Complete specification.)

**401. Improvements in under-running current collectors for electric railways.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**402. Improvements in thermal-electric cut-outs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**403. Improvements in and relating to electric heaters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**404. Improvements in electric switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**405. Improvements in electric resistances.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**410. An improved electrical hydro-pneumatic governor for marine engines.** Rodolphe Jean William Grasset, Palace-chambers, Westminster, London. (Complete specification.)

**416. Improvements in or relating to electric insulators.** Henry Julius Trautmann and James Lloyd Copping, 111, Hatton-garden, London.

**417. Improvements in or relating to electric switches.** Henry Julius Trautmann and James Lloyd Copping, 111, Hatton-garden, London.

**424. Improvements in or relating to single lines of railway on the electric staff or other electric systems.** Charles Mark Jacobs, 70, Chancery-lane, London.

**432. Improvements in arc lamps.** George Blackford Bryan, 46, Lincoln's-inn-fields, London.

JAN. 10.

**446. An apparatus for testing and indicating the intensity of electric currents in cables or other conductors.** Wilfrid Branfield, Bank-buildings, George-street, Sheffield.

**493. Improvements in or relating to apparatus for measuring the strength or intensity of electric currents.** Otto Titus Blathy, 111, Hatton-garden, London. (Complete specification.)

**512. Improvements in and relating to electric generators.** Philip Dawson, 1, Queen Victoria-street, London.

**513. Improvements in alternating-current commutator motors.** Arnaldo Paolo Zani, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**521. Improvements in secondary batteries.** Pierre Meusnier and Guillaume Mounier, Norfolk House, Norfolk-street, Strand, London.

**522. Improvements in and relating to electric oil switches.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**523. Improvements in electric meters.** The British Thomson-Houston Company, Limited, and Frank Holden, 83, Cannon-street, London.

JAN. 11.

**530. Improvements in or relating to electric railways and trains.** Henry Courteen, The Homestead, Mill End, Rickmansworth, Herts.

**534. Improvements in twin or double carbon arc lamps.** Veritys, Limited, and Frederic Stanhope Worsley, 11, Burlington-chambers, New-street, Birmingham.

**535. Improvements in and relating to the lighting of electrical lamps by a self-connecting pole.** John Smith, 68, West Regent street, Glasgow.

**542. An improved electric switch or cut-out.** John Maclean, 100, Wellington-street, Glasgow.

**571. A method of and apparatus for indicating or checking the efficiency of electric train or car driving.** William McLellan and Charles Hesterman Merz, Norfolk House, Norfolk-street, Strand, London.

JAN. 12.

**605. An improved method of separating bodies capable of being magnetised from others with which they are associated.** Henry Ernest Bennett, James Rodda, and Thomas Henry Rule, Mayfair Villa, Eny's-road, Camborne, Cornwall.

**606. Improvements in portable electric drilling machines.** John Maclean, 100, Wellington-street, Glasgow.

**617. An improved construction of splicing ear for electric trolley wires or the like.** Thomas Ernest Raymond Phillips, 1, Broad-street-buildings, Liverpool-street, London.

**618. An improved method of controlling the feeding mechanism of electric arc lamps of the open and enclosed types.** Walter John Fry, 66, Tubbs-road, Harlesden, London.

JAN. 13.

**689. Automatic current feeder for electric railways.** Richard Duckworth, Henry Duckworth, and David Kerr, 45, Lower Bank-road, Fulwood, Preston. (Complete specification.)

**693. Improvements in and relating to electric incandescent lamps.** Sydney Heathcote Penning, 1, Heath-villas, Plumstead Common, London.

**700. Improvements in electric transformers for high-tension currents.** Hermann Heinicke, 3, Upper Vernon-street, London. (Complete specification.)

**718. Improvements in and relating to reverse-current electric cut-outs or circuit breakers.** The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

JAN. 14.

**776. Improvements in alternating-current electromagnets.** Arnaldo Paolo Zani, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**778. Improved manufacture of accumulator plates.** Arthur George Bloxham, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Ferdinand Eduard Polzeniusz and Robert B. Goldschmidt, Belgium.)

**789. Improvements in the electric heating of electrically-propelled vehicles.** The Union Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 16, 1904, being date of application in Germany.) (Complete specification.)

**797. Improved construction of electric fuse or cut-out apparatus.** Anthony Bernard Tubini, 173, Fleet-street, London.

JAN. 16.

**835. A new or improved apparatus for condensing steam and producing or generating electricity.** Edouard Laurent Celestin Mollard and Gerard Featherstone Griffin, 33, Chancery-lane, London.

**839. Improvements in electric storage battery negative-pole plates.** Alfred Julius Boult, 111, Hatton-garden, London. (Edward Wanton Smith, United States.) (Complete specification.)

**860. Improvements in trolley heads for overhead system of electrical traction.** John Alexander Orme, 46, Lincoln's-inn-fields, London.

**881. Improvements in or relating to apparatus for indicating consumption of electric energy and loss of current.** Fritz Wieland, 111, Hatton-garden, London. (Complete specification.)

JAN. 17.

**883. A new electrical immovable contact breaker and switch for ignition purposes on petrol motors, oil and gas engines.** Rowland Hughes Jones, Vronlaulog, Colwyn Bay.

**923. Improvements in electrical measuring instruments.** Frank Conrad, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Jan. 20, 1904, being date of application in the United States.) (Complete specification.)

**934. Improvements in apparatus for producing high-potential electric discharges, particularly for igniting the charge of an internal-combustion engine.** Arthur Harold Nicholson, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**948. Improved construction of electric fuse or cut-out apparatus.** Anthony Bernard Tubini, 173, Fleet-street, London.

**952. Improvements in and relating to electric motors.** Marius Latour, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 18, 1904, being date of application in France.) (Complete specification.)

**954. Vapour electric apparatus.** Alexander Churchward, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 18, 1904, being date of application in United States.) (Complete specification.)

**955. Improvement in vapour electric apparatus.** Samuel Ferguson, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 18, 1904, being date of application in United States.) (Complete specification.)

**956. Improvements in vapour electric apparatus.** Howard Irving Wood, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 18, 1904, being date of application in United States.) (Complete specification.

JAN. 18.

**1004. Improvements relating to dynamo-electric machines.** William David Seton Brown and Arthur Greenwood, 6, Breams-buildings, Chancery-lane, London.

**1009. Improvements in electrical connections for secondary batteries or accumulators.** Chaimsonovitz Prosper Elieson, 7, Southampton-buildings, Chancery-lane, London.

Digitized by Google

**967. Improved semi-portable electric hand lamp.** Harry Willis, 260, Stapleton-road, Bristol.

**991. Improvements in electric switching apparatus.** John Leemann, 115, Fore-street, London.

**1015. Improvements in electrical accumulators or storage batteries.** Antonio Galanti and Redmond Barrett, 4, South-street, Finsbury, London.

**1017. Improvements in apparatus for the electrolytic treatment of gases.** Axel Larsen, 4, South-street, Finsbury, London.

**1022. Improvements in electric switches.** John Cox Dear, 40, Chancery-lane, London.

JAN. 19.

**1065. Improvements in incandescent electric light bulbs.** Martin Charles Burt, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**1072. Incandescent electric lamps.** Royal Gerow and George Hilliard Gerow, 4, South-street, Finsbury, London. (Complete specification.)

**1079. Improvements in electric distribution systems, applicable more especially to systems employed in train-lighting.** Allgemeine Elektricitäts-Gesellschaft, 83 Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 20, 1904, being date of application in Germany.) (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published Feb. 9.*

1904.

**1106. Electric incandescence illuminating apparatus.** Francis.

**3449. Electric clocks.** Campiche.

**4772. Controlling alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**4773. Controlling alternating-current motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**5113. Transmitters suitable for wireless telegraphy.** Marconi's Wireless Telegraph Company, Limited, and Gray.

**5146. Dynamos and electric motors, with a view to preventing or lessening sparking at the brushes.** Armistead.

**5296. Electric fuses and fuse-boxes.** Davies.

**6402. Electric insulating compositions.** British Thomson-Houston Company, Limited. (General Electric Company.)

**6433. Electric switches.** London Electric Supply Corporation, Limited, and Partridge.

**6585. Saddle for carrying electric cables.** Sharp.

**6999. Manufacture of cement for use in electric lamps and for other purposes.** Cleminson Electric Lamp Attachment, Limited, and King.

**6996. Appliances for the manufacture of conduits for electric cables.** Sutton and Gregson.

**7489. X-ray apparatus.** Gaiffe.

**10119. Method of and means for adapting "electric candles" to sconces and the like.** Regnart.

**14933. Mode of protecting life from the "live-rail" danger on electric railways.** Curwen.

**20010. Holder for incandescent electric lamps.** Regnart, and Hunter Electric Candle Lamp Company, Limited.

**23653. Electric motors.** Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

**25072. Protection of conductors and insulation of flexible cords for electrical apparatus.** Galsworthy.

**26269. Coils for electromagnets, solenoids, and the like.** Sipe.

**27348. Electrical switches.** Eason.

**27537. Vapour electric apparatus.** Wood. (Date applied for under International Convention, Dec. 17, 1903.)

**27705. Alternating-current electric motors.** Lamme. (Date applied for under International Convention, Feb. 27, 1904.)

**27713. Process for the formation of incandescence bodies for electric incandescence lamps.** Thompson. (Deutsche Gasglühlicht Akt.-Ges. (Auergesellschaft).)

**27714. Electric incandescence lamp with incandescence body fused in the conducting wires.** Thompson. (Deutsche Gasglühlicht Akt.-Ges. (Auergesellschaft).)

* Includes maintenance of permanent way and proportion of profits paid to the tramway companies for term of unexpired lease. e Train mile.
b Per mile of single track. c Include rail and tram. d Including depreciation. f Including one section of horse traction. g 1903. h Half-year's figures.
Only eight months—expenditure includes large special items incidental to starting new department.

Digitized by Google

## NOTES.

**British Association.**—It is announced that Mr. G. H. Goch, the mayor of Johannesburg, will act as vice-president of the British Association during the visit to South Africa.

**Royal Institution.**—Prof. G. H. Bryan being unable to lecture on Friday evening, March 24, Sir Oliver Lodge, LL.D., D.Sc., F.R.S., will deliver a discourse on that date on "A Pertinacious Current." Sir Stirling Maxwell being unable to lecture, Mr. Thomas G. Jackson, R.A., will on Thursdays, March 23 and 30, deliver two lecture on "The Reasonableness of Architecture" (illustrated by lantern slides).

**Turbines.**—Some statistics issued by Lloyd's illustrate the growing use of the turbine for navigation. During 1904, 13 turbine vessels, aggregating some 42,000 tons, were launched. In addition to this there are at the present time under construction in the United Kingdom, besides the two large express steamers for the Cunard Company, five vessels totalling about 29,500 tons, which are to be fitted with steam-turbines.

**Glasgow Section.**—For their annual smoking concert, which is to be held to-morrow night in the Banqueting Hall of the Grosvenor Restaurant, Glasgow, at 7.30, we note that this section have organised an extensive and varied programme. Songs (humorous and sentimental), recitations, instrumental music, and miscellaneous items figure on the card, so that the entertainment of the party has been well looked after.

**International Electrical Units.**—The Foreign Office has under consideration, on the report of experts who attended the St. Louis Congress, the question of international uniformity in electrical units. It is stated that a joint commission will in all probability assemble before long at Geneva or The Hague to arrange such a system, in terms of the volt, ampere, and ohm. Many important countries, including Russia, Norway and Sweden, Denmark, the Netherlands, Italy, and Japan, have not yet legalised any electrical units.

**Royal Meteorological Society.**—The council of this society have arranged to hold an exhibition of meteorological instruments from March 14 to 17 next at the Institution of Civil Engineers. The exhibition will be chiefly devoted to recording instruments, but it will also include new meteorological apparatus invented or first constructed since the society's last exhibition, as well as photographs, drawings, and other objects possessing meteorological interest. Intending exhibitors are invited to communicate with Mr. William Marriott, the assistant secretary.

**Glasgow Electricity Department.**—The annual festival of the staff engaged in the Corporation's electricity department was held in the Queen's Rooms, Glasgow, on Friday last. Bailie Willock, who presided, gave a short sketch of the progress of the department, showing that the Corporation's electricity undertaking was now a paying concern, which yielded an annual revenue sufficiently large to silence the critics of the enterprise. He alluded in appreciative terms to the services of Mr. C. H. K. Chamen (the brother of the chief engineer), who has been appointed superintendent of mains to the Lancashire Electric Power Company. Vocal and instrumental performances contributed to the entertainment of the party, who spent a highly agreeable evening.

**Societe Belge d'Electriciens.**—We have received the January *Bulletin* of this society, which contains a number of communications of interest. The first of the papers, which is commenced in this issue, is one by Messrs. H. Haller and H. Hoern on "Modern Electrical Lifting Apparatus." The authors are engineers to the Internationale Electric Company of Liége, and a large amount of the apparatus described is actually manufactured by this firm. Good descriptions are given of electric lifting blocks, and there is a long description of a single-rail traverser, also operated by electricity. Mr. Carlier, one of the engineers to the State railways, is responsible for a paper on "Apparatus for Measuring Simultaneously the Time, Distance Travelled, Speed, and Acceleration of Trains." The volume is completed by reports as to the progress of the association in 1904.

**Engineering Standards Committee.**—We have received a copy of Report No. 10, which deals with standard tables of pipe flanges. The sub-committee appointed to investigate this subject held 24 meetings, at which they considered a large amount of matter collected from manufacturers and users of pipes of various classes. They were also greatly assisted by numerous experimental tests on specimens of flanges and joints lent by the Admiralty and several private firms. The committee recommended that flanges, etc., should be standardised in the following four classes: Low-pressure standard for steam pressures up to 55lb., and water pressures up to 200lb. per square inch; intermediate-pressure standard for steam pressures over 55lb., but not exceeding 125lb. per square inch; high-pressure standard for steam pressures over 125lb., but not exceeding 225lb. per square inch; and extra high-pressure standard for steam pressures over 225lb., but not exceeding 325lb. per square inch. There are sections upon the dimensions of flanges, number of bolts, and sizes of same. The report is supplemented by complete tables of dimensions.

**Iron and Steel Institute.**—Members of this association are invited to participate in an international congress of mining, metallurgy, mechanics, and applied geology, to be held at Liége on June 26 to July 1, 1905, in connection with the international exhibition. The subscription to the congress is £1, and members should enter their names in the section of which they wish to receive the publications. The general secretary of the organising committee is Mr. Henri Dechamps, 16, Quai de l'Université, Liége. The subjects to be dealt with in the metallurgical section comprise coke manufacture; blast-furnace practice; influence of titanium, arsenic, and other substances on iron and steel; removal of dust from blast-furnace gas; slag cement; use of poor gas as motive power in rolling-mills; new methods of open-hearth steel manufacture; alloys of steel with chromium, nickel, manganese, vanadium, and tungsten; the forging press and steam hammer; electro-metallurgy and the practical applications of metallography. Visits to the exhibition and to scientific and industrial establishments will be arranged. Further particulars may be obtained from the offices of the Iron and Steel Institute.

**Cables and War.**—At University College on Tuesday Sir John Macdonald delivered an opportune lecture on "Submarine Cables from the Point of View of International Law," this being the first subject dealt with in a resumed law course on the "Rights of Neutrals." The lecturer remarked that very little had been done by way of treaty or convention to decide the rights of nations to destroy cables while at war, notwithstanding the importance of the question. The Institute of International Law adopted a resolution that cables between neutral countries should not be cut, but between two belligerent countries, or two parts of a belligerent country, they might be cut at any point except in territorial or neutral waters. At the instance of the French Government a conference was held in 1884 to consider the protection of telegraphic communication, and under the convention which followed injury to a cable was

Digitized by Google

punishable as a crime. The convention did not, however, interfere with the rights of nations at war. The lecturer concluded with the statement that no satisfactory solution would be arrived at unless it were agreed that in case of damage compensation should be paid to the owner, except the cable belonged to a belligerent country.

**The County of London Electric Power Company.** The Bill to authorise this mammoth scheme provides that dividends shall be limited to 8 per cent. until the price of power has been reduced below that of the preliminary schedule, ranging from 1½d. to just over ¾d. per unit. This has not sufficed, however, to ward off opposition, and it is evident that the London County Council will again be to the fore in resisting any such scheme. In an interview the other day, Mr. J. Allen Baker, the chairman of the Highways Committee, stated that the Council expected to provide themselves with energy, when the generating station at Greenwich has been completed, at a cheaper rate than any bulk-supply company could. Mr. Baker proceeded to state that he would "not be surprised if we can supply ourselves at less than 1d. a unit," which does not seem to imply any economy over the tariff named by the company for extended supply. The promoters of the scheme include several influential names, and a big combat between private and municipal enterprise is likely. It is hinted that the London County Council may, at the request of the boroughs, revive their Bill for constituting the Council the supply authority for the Metropolis.

**Rugby Engineering Society.**—A course of three lectures is to be given on the evenings of Feb. 24 and March 10 and 24 by Mr. J. T. Milton, chief engineer-surveyor to Lloyd's Register, the subject being "The Minute Structure of Metals." The following is a synopsis: Mechanical properties of metals dependent upon their minute structure—Examples of extreme divisibility of metals—Power of microscope in ascertaining minute structure of metals—Use of cooling curves in the study of alloys—Analogies between pure metals and water, and between alloys and aqueous solutions—Definition of eutectic alloys—Illustration by series of lead-tin alloys—Crystallisation of metals—Orientation of crystals—Effect of heat treatment both during and subsequent to freezing—Definition of solid solutions—Diffusion and segregation—Molecular motion and transference—Illustrations in brass and Muntz metals—Difficulty of drawing a line between iron and steel—Usual impurities or components of commercial iron and steel—Their influence upon structure—Definitions of ferrite, cementite, pearlite, austenite, etc.—Roberts-Austen's diagram—Critical temperatures—Effect of heat treatment on structure. The lecturer will show many diagrams and a large collection of typical metals and alloys.

**Municipal and County Club.**—This club held a very successful house dinner on Friday, the 27th ult., the guest of the evening being Sir William J. Collins, chairman of the Education Committee, London County Council. Mr. G. Laurence Gomme, clerk to the London County Council, presided, and a number of distinguished members were present. Mr. Gomme, in proposing the toast of the guest, said that Sir William Collins was known to all as a distinguished member of the London County Council, and as one of the ablest of its past chairmen. If it should happen among the political fortunes of the future that Sir William should transfer his sphere of action to another place, they felt sure that that other place would feel his influence. He considered that the County Council had dealt brilliantly with their new work in connection with education. Sir William Collins, in responding, observed that it had been truly said that a sound system of local government was a sure keystone of our political liberties, in as far as they found Parliament sometimes paralysed by the volume of work it endeavoured to undertake. It would devolve more and more upon local administrators to relieve Parliament of administrative work. After dinner an excellent musical programme was arranged under the direction of Mr. T. F. Noakes.

**The Metric System.**—The report of the Decimal Association for the past year is an optimistic document. After recording the passage through the Upper House of the measure introduced by Lord Belhaven to render the metric system compulsory, the report states that as the result of a special canvass amongst the Commons over 330 members promised their support. The number would not need to be many in excess of 330 to secure a majority in a full House. Every effort will be made, the report states, to carry the Bill through the Commons during the coming session. Mention is made of the favour with which the system is viewed in the Colonies and the United States, and the report alludes to the resolutions passed by the Associated Chambers of Commerce, the Society of Accountants and Auditors in London, and other institutions, who agreed to cordially support the measure. The receipts for the year totalled £1,544, against £768 for the previous 12 months, but the expenses of the compaign swamped the income and left the association with a debit balance. Since March 1, however, the organisation has received an accession of 377 members. Our own views on the matter have been expressed recently in our editorial columns. With Parliament as at present constituted said to be so favourably disposed towards the measure, it is no wonder that the Decimal Association are in a hurry to get it through in the ensuing session, lest—but that is another story.

**Personal.**—A representative meeting of the subscribers to the testimonial to Mr. Musgrave Heaphy was held in the Board-room of the Phœnix Fire Office on Friday afternoon last. In the unavoidable absence of the Right Hon. Lord Avebury, chairman of the committee, Mr. H. B. Guernsey, manager of the Phœnix Fire Office, occupied the chair. The chairman, in his opening remarks, said that Mr. Heaphy was an old friend and valued colleague, and that for a great number of years he had been loyally devoted to the interests of the company, gaining the respect of everybody. They were all sorry to lose him. It was always Mr. Heaphy's desire that installation work should be done in the best possible way, and the electrical profession, the fire offices, and his co-workers had every reason to be proud of the work he had accomplished. It was an open secret that Mr. Heaphy's ill-health was the result of continuous and strenuous services in the best interests of his profession. It was decided that the presentation should take the form of an engrossed address, a gold watch and chain, and an album with the signatures of the subscribers. In seconding the address, Mr. Alex. Siemens, president of Institution of Electrical Engineers, referred to the fact that to Mr. Heaphy belonged the honour of preparing the first set of rules for guidance in the erection of electrical installations. Owing to the present state of Mr. Heaphy's health, it was decided to convey the testimonial to him privately.

**New Publications.**—The Universal Electrical Directory (J. A. Berly's): Messrs. Alabaster, Gatehouse, and Co. have forwarded us a copy of the 1905 volume of this old-established reference book. It is divided into four sections—viz, British, Colonial, Continental, and the United States—each of which is again divided into alphabetical and classified sections, and in the case of the British a geographical section is also given. The entire publication has, as usual, been completely revised, and now comprises nearly 33,000 names, besides other information, so that its value is

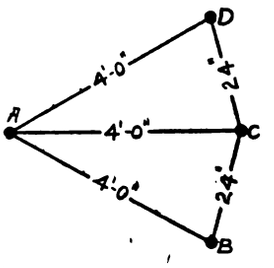
Digitized by Google

obvious. The price is 14s., post free.—The first volume of the *Transactions* of the Faraday Society in its new form is an excellently got-up publication, and contains several interesting papers recently read before the society, with the discussions.—The January number of the *Electric Club Journal*, Pittsburg, has as its frontispiece an illustration of a horizontal boring and drilling machine driven by a variable-speed direct-current motor. There are articles on "The Installation of a Transmission Plant," "The Application of Motors to Machine Tools," "Opportunities in the Electrical Business," "Dampers for Synchronous Machines," "Protective Apparatus," and "Oil-Saturated Commutators," while Messrs. H. W. Peck, E. H. Dewson, and R. E. Workman continue their series of articles on "Modern Practice in Switchboard Design," "Electric Railway Braking," and "Factory Testing of Electrical Machinery" respectively.

**Association of Technical Institutions.** — The Association of Technical Institutions held its annual general meeting on Friday last at the Municipal School of Technology, Manchester. After a vote of thanks had been unanimously accorded to the retiring president, Sir John Gorst, the newly-elected president, Sir Philip Magnus, said that the transfer of the work of the school boards to municipalities and county councils was a great step in advance. The closer association of Whitehall and South Kensington, the abolition of separate departments of science and art, and the recognition of the true place of science and art teaching in all curricula, the creation of one central authority for elementary and secondary education, and the acknowledgement that technological instruction was a matter of State concern as supplementing both, were epoch-making incidents in the history of education in this country. Sir Philip then proceeded to deal with the handicap which frequently confronted technical instructors because students who attended even the most elementary technological classes were often insufficiently prepared to profit by the teaching. They were deficient in power of expression; they lacked practical knowledge of arithmetic and the rudiments of science and the necessary skill in drawing. The lesson he deduced from this was that elementary teaching should be made more practical. He "believed that the workroom would gradually supersede the classroom in elementary schools, and that manual training would become the central feature of the training around which other studies would be grouped." At the other end of the scale the relations of technical institutions with the universities, in so far as the latter provided such teaching, were not yet fully adjusted. He concluded by appealing for greater access to the universities. In the evening the president and members of the association were entertained at dinner, at the Midland Hotel, by Sir William Mather, M.P., who, in proposing "Success to the Association," remarked that we should not occupy as prominent a position 25 years hence as we had in the past quarter or half century, unless greater attention were paid to technical education.

**Overhead Wires.**—Under the auspices of the Commons and Footpaths Preservation Society, the Postmaster-General received on the 26th ult. the deputation referred to in our last week's issue. Mr. Shaw-Lefevre, who introduced the deputation, was supported by, among others, Lord Farrer, Sir N. Fowell Buxton, Admiral Sir E Fremantle, Prof. Westlake, K.C., and Mr. F. Carruthers Gould. Mr. Shaw Lefevre said that the variety of interests represented showed the widespread feeling of alarm at the action of the Post Office. He argued that in no circumstances ought the lines to be carried over commons, and as to rural roads, although he quite admitted that they had to consider the balance of public convenience, it was thought that an effort should be made to prevent the disfigurement of roads of exceptional beauty. He quoted a letter from the President of the Royal Academy, in which Sir E. Poynter referred to the "hideous disfigurement of natural scenery," instancing the beautiful road along the Hog's Back, Surrey, which, he said, had been cruelly disfigured by telegraph posts. He expressed the hope that there was no truth in the rumour that the Government intended to reintroduce the Bill which would give further powers to the Post Office, and said the fact that the London County Council refused consent for wires and poles on any commons or parks under their jurisdiction was strong testimony in favour of the policy the deputation recommended. In a sympathetic reply, Lord Stanley assured the deputation that, as a general rule, he would be prepared, where there were two routes, to follow the less beautiful one, even though it were longer. The Post Office, however, was in an unenviable position, as it was expected to supply the public needs as cheaply as possible. Telegraph wires were to a large extent being laid underground, but this course was not practicable with trunk telephone wires, as it impaired their efficiency. His lordship intimated that the Department were greatly handicapped in respect to wayleaves, their choice of route often being restricted in consequence. He promised, however, to give careful consideration to any representations concerning threatened landscapes, and reassured his audience by stating that he had no intention of reintroducing the Bill of last session with the open-spaces clauses in it.

**Underground Waterflow**—Investigations as to the direction in which underground water travels are frequently necessary on the part of civil engineers in connection with water-supply schemes. In the *Journal* of the Western Society of Engineers, published at Chicago, there is an interesting description of some experiments made on the flow of such underground waters in Southern California. Amongst other means of investigation, the author, Mr. C. S. Slichter, describes an electrical one, with which he has carried out investigations at considerable depth. It consists of sinking four boreholes, as illustrated in the accompanying diagram. Where the wells are not driven

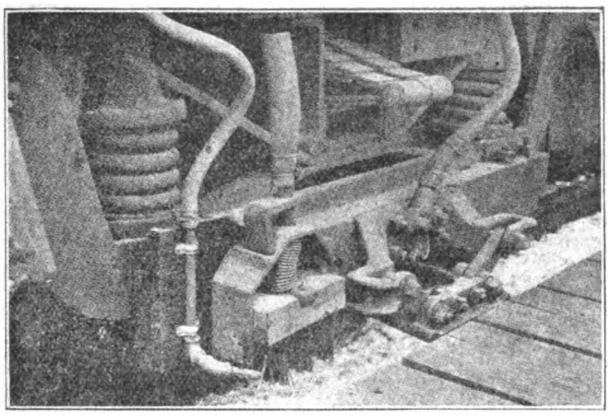


deeper than 25ft., an "up-stream" well, A, is located, and three other wells, B, C, and D, are driven at a distance of 4ft from A, the distance between B and C and C and D being about 2ft. The well C is located so that the line from A to C will coincide with the probable direction of the expected ground-water movement. If experiments are to be carried on more than 25ft. below the surface, the dimensions of the triangle are increased, and with depths exceeding 75ft., an interval of 8ft. or 9ft. between the boreholes is chosen. Having sunk the boreholes, electrical connection is made with the casing of each test-well. In each of the down-stream wells a screened electrode is then inserted, connection with which is maintained at the surface by rubber-covered wire. The method of investigation consists of keeping a regular record of the resistance between the well casing and this screened electrode. All the time the resistance of the water inside the well is constant, a constant reading is obtained from

Digitized by Google

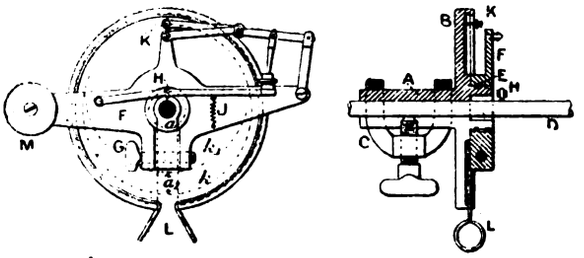
the apparatus. The next step is to insert in the up-stream well a certain amount of sal-ammoniac, which will be dissolved by the ground water, and carried down stream with the same. As this saturated water reaches the other three wells the resistance readings will be altered, and from the data so obtained both the direction and speed of flow of the underground water is determined. The author gives a number of curves to show results in actual experiments, from which we gather that the method is quite a practical one.

**Sleet on Third Rail.**—The sleet problem on a third-rail system becomes more difficult where the cars do not run frequently enough to prevent the sleet from re-forming after removal. Having made some satisfactory tests last winter, the Aurora, Elgin, and Chicago Railway has adopted the following remedy, described in the *Street Railway Journal*. A solution of calcium chloride, which does not have the corroding effects of common salt solution, is employed.

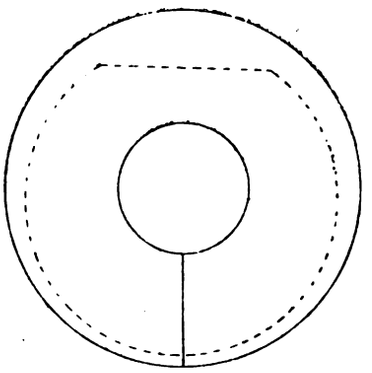


As shown in the accompanying illustration, a small pipe is connected to a rubber hose leading to the driver's cab. Through this the solution is led to the rail a few inches in front of the steel sleet brush. This brush, passing immediately afterwards, spreads the solution uniformly over the film of ice before it has had time to run over the side of the rail. Each car is equipped with four such pipes, one in front of each of the four shoes, so that no matter on which track or in which direction the car may be travelling, one of the pipes may be put in service. The hose to which the pipes are attached are connected to the discharge pipes of a 40-gallon can placed in the cab, and containing the solution of calcium chloride. As the solution is a conductor, it is necessary to ground the pipe on the truck frame to prevent the can in the cab from becoming charged, and consequently dangerous to the operators. The result, of course, is a current from the third rail to the truck by way of the stream of liquid, but the conductivity of the stream is not great enough to cause a dangerous current. The solution is composed of about 38lb. of calcium chloride to the cubic foot, say 7½ gallons, of warm water. When running at full speed the whole flow from the ¼in. pipe is thrown on the rail. The expense of installing the apparatus is comparatively small, and practically the only working cost is for the chemical, which, at the usual market price in the States, works out at about 3½d. per mile.

**Measuring the Wear on Trolley Wires.**—The following apparatus has been designed by Mr. M. A. Harrich, of Ratisbonne, to record graphically the wear on a trolley wire at any part of a tramway system. As seen in the first diagram, the apparatus, which is described in *L'Industrie Electrique*, consists of a tube, A, which carries a disc, B, of considerable diameter. The tube is secured on to the wire by means of the screw which is seen in the illustration. The other part of the apparatus is free to move round on the turned surface, E. On this movable part is fixed a system of levers, on which the touching point, H, rests against the wire the wear of which is to be determined.



As this movable part is revolved the movement of the pointer, H, is magnified by the system of levers which connects it with the pencil, K. The ratio of these levers is such that any movement of the point, H, is increased 10 times at the recording point, K. This pencil leaves a trace on a paper, which is secured against the disc, B, by means of springs. Fig. 2



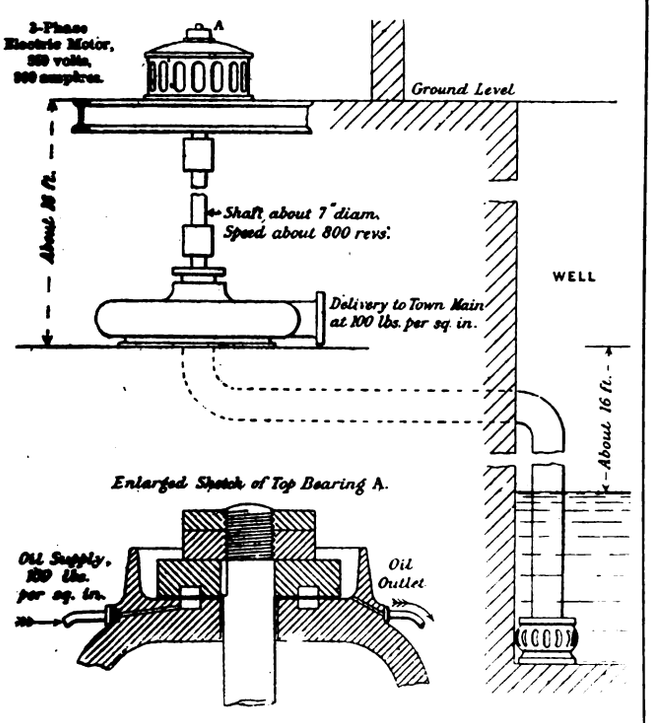
is a diagram taken with the apparatus, which gives a magnified contour of the wire. The actual area of the figure shown is 100 times that of the wire itself. With this apparatus one can easily take the sections of the trolley wire at intervals, and keep a regular record of the wear. The frequency at which the records should be taken depends, of course, on the traffic, and it is necessary to take them more often at curves and points where the wear is excessive. The apparatus is constructed in Hanover by Messrs. Dreyer, Rosenkranz, and Droops.

**Speed Limits.**—In our issue of Dec. 16 we referred to the representations made by the Tramways and Light Railways Association to the Board of Trade upon the relative speed limits for trams and motorcars respectively. In their reply the Board dissent from the view that, except on very sharp gradients, trams may safely be allowed to run as fast as motorcars. Presumably, the Board, in taking this stand, are actuated by the greater mobility of the latter vehicle, though no reason is stated. The question of prescribing a general speed limit for trams has frequently been considered by the Board, who have come to the conclusion that, in order to grant the maximum speed consistent with the public safety, it is necessary to maintain the present practice of dealing with each route on its merits. The Board intimate their desire to assist tramway enterprise, and will be ready to consider any application for an increase of speed on any particular line. In a somewhat spirited rejoinder to this communication the association aver that in the opinion of many of their members, experts in tramway management, the present speed limits for trams could be generally extended with safety. The association quote the case of the motor omnibus now running in West London. This vehicle goes from Piccadilly-circus to Kensington Church, a distance of over 2 miles 1,000 yards, in 13 minutes. This represents a speed, inclusive of stops, of over 12 miles an hour. When

Digitized by Google

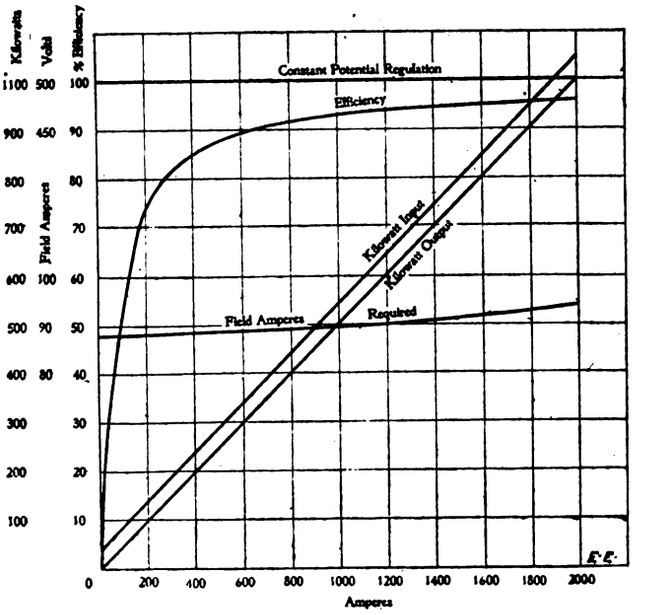
allowance is made for stops and for slackening in the crowded parts of Piccadilly and Knightsbridge, it signifies a running speed, for parts of the journey, of considerably over 14 miles an hour. This speed has been maintained with perfect safety. As compared with this the speeds granted on the London County Council tramways do not exceed 10 miles, except for a small stretch near Clapham Common, and are limited to eight, six, and four miles an hour at other places. The maximum running speed on the London United lines is 12 miles an hour on about 6 miles only of the 35 route miles in operation, and on the remaining 29 miles, 10 miles or less, though none of these tramways are within four miles of Charing Cross. In the northern suburbs the Metropolitan Company were recently refused a speed limit of 16 miles an hour in such a rural neighbourhood as that between Edgware and Cricklewood. Thus we have in London the curious contrast of a high speed for public service cars (other than trams) in crowded central streets and a low speed for trams in outlying suburbs. The association offer to organise tests of the relative stopping power of the tramcar and the motor omnibus or other autocar. In conclusion, the association suggest that, if the Board will not pass a general regulation, they should follow the practice of the Local Government Board in regard to motorcars by holding a local enquiry at which the objection to greater speed can be tested by evidence.

**High-Pressure Centrifugal Pump.**—In the paper read by Mr. A. J. Gimson before the Institution of Mechanical Engineers on his "Impressions of American Workshops" there is a good description of a large horizontal pump which is electrically driven. This pump is used at the Schenectady waterworks. As the illustration



shows, it consists of an electric motor, with its axis vertical, carried by girders at the ground-level and connected by a vertical shaft to the centrifugal pump. The three-phase motor is supplied with current at about 550 volts, 800 amperes, and the speed of motor and pump is about 800 revolutions per minute The centrifugal pump is about 6ft. internal diameter, and raises water from an adjoining well, the level being about 16ft. below the pump. The water is pumped into mains against a pressure of 100lb. per square inch. There is also a small auxiliary electrically-driven geared vacuum pump to exhaust the main pump and suction pipe from the well for charging purposes, also a set of small electrically-driven geared three-throw pumps to pump oil at 100lb. per square inch under the upper collar bearing of motor on which the weight of the armature, shaft, and pump disc all hang, so that the whole of moving parts are floating on an oil step bearing above, as shown in the accompanying diagram. The pressure of oil in the annular space between the two bearing discs just eases them apart, and takes the whole weight (amounting to several tons) of working parts. The water to be pumped amounts to over eight million gallons per 24 hours, which works out at about 500 pump horse-power.

**Approximate Determination of Alternator Regulation.**—In his serial article on "Factory Testing of Electrical Machinery," appearing in the Electric Club *Journal*, Pittsburg, Mr. R. E. Workman describes a method for determining approximately the regulation of an alternator from the open-circuit saturation curve and the armature short-circuit curve, where it is impracticable to obtain the regulation curve directly. The accompanying diagram



shows the regulation, calculated in this way, for a 1,000-kw. 500-volt alternator, with the following data: armature resistance from terminal to terminal at 50deg. C. equals 0 00405 ohm; the current per phase at full load equals 1,154 amperes; the I.R drop is 4·05 volts; the field amperes at 504 volts from the saturation curve equal 88 8; and the field amperes at 2,000 total amperes on short-circuit equal 30, the resultant field amperes equalling 93·8. With this field current the open-circuit voltage from the open-circuit saturation curve would be 527, so that the inherent regulation for full load with constant field current would be 5·4 per cent. The regulation curve shown in the diagram is that for constant potential, so that it is only necessary to calculate the field amperes required, with a number of different currents, to give the full terminal E M.F. of 500 volts. The method of computing the regulation consists of adding the armature resistance drop for a given load to the terminal voltage on open circuit. From the no-load saturation curve determine the field current corresponding to this voltage, and add this field current vectorially to the field current required to produce the same load with the armature short-circuited, these two quantities differing in direction by 90deg. Then from the open-circuit saturation the voltage corresponding to this resultant field current is found. The difference between this voltage and the terminal voltage of the armature at the chosen current, expressed as a percentage of the latter, is the regulation of the alternator for that particular current.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

(*Continued from page 116.*)

In passing from Fig. 6 to Fig. 7 it will have been noticed that attention has been naturally diverted from the *number of spirals* upon the armature to the *number of inductors*. This must always be so in the case of drum windings. Of course, such a section as that accentuated in Fig. 7 might be (and frequently is) considered as one spiral; but in complicated drum windings of many inductors it is very much more convenient to consider the number of inductors than the number of such spirals. Thus in future we shall rarely speak of the number of spirals in the case of a drum-wound machine.

Windings like Fig. 7 are known as *multiple-circuit drum windings*, and we may formulate a set of rules which will apply to all such armatures. These rules will be as follows:

**Rules for Simplex Multiple-Circuit Drum Windings.**

(1) The number of inductors must be divisible by 2.

(2) Rule for connecting: number every other inductor; start from No. 1, connect across to an inductor situated approximately $\frac{1}{p}\,w$ from No. 1 (where $w$ is the number of inductors, $p$ the number of poles), such an inductor being an unnumbered one; and then pass back to No. 2.

(3) To ensure re-entrancy, the distance between inductors Nos. 1 and 2 should be equivalent to $\frac{2}{w}$ of the total circumference if the winding is to be regular.

Now, the above rules, though accurate, are not convenient in practice, for it is not possible to draw out every armature with all its inductors and number them as suggested above. We can easily re-form the above rules as follows:

If we number *all* the inductors in Fig. 7 instead of only half of them, beginning with the same inductor as before, we find that all the original numbered inductors are now odd numbers, the unnumbered ones becoming the even numbers. Since in the original diagram we went from a numbered to an unnumbered inductor, we must now go from an odd to an even number, and so on. Thus in Fig. 7 we have connected No. 1 to an inductor lying between 3 and 4. Under the new arrangement (Fig. 8) this would be connecting No. 1 to No. 6, and we shall then pass back to what was originally No. 2, but is now No. 3. Thus our connections will go 1, 6, 3, 8, 5, and so on; it being understood that connections 1 to 6 and 3 to 8, etc., are at one end of the armature, 6 to 3 and 8 to 5 at the other end.

In Fig. 8 the connections 1 to 6, 3 to 8, etc., are shown at the front or commutator end of the armature, while connections 3 to 6, 5 to 8, which are supposed to be at the other end of the numbered inductors, are drawn as dotted lines outside the armature. This plan we shall pursue in all future figures, since it makes the diagram much clearer.

Fig. 8 is exactly the same as Fig. 7 except that all the inductors are now numbered, and nothing of the original appearance of a ring winding is left. These two diagrams, when compared with the preceding ones, show very clearly the close connection existing between ring and drum windings. Indeed, it is not too much to say that in all cases of difficulty with multiple-circuit drum windings, if the corresponding ring be drawn out, any intricacy or confusion at once vanishes.

To develop the new rules for multiple-circuit drum windings, we remember that the difference between the numbers of any two inductors connected together is called a *number-pitch* of the winding, so that the arrangement in Fig. 8 is said to have a forward number-pitch of 5, and a backward number-pitch of 3. Both these numbers must always be odd, since in any single winding we always connect from an inductor with an odd number to one with an even number, or *vice versâ*, as has been already explained. The difference between the number-pitches (forward and backward) must be 2, since we have shown that in each case we must return to the inductor next but one to that from which we started. Part of the winding in the figure has been again accentuated so as to bring out clearly its character.

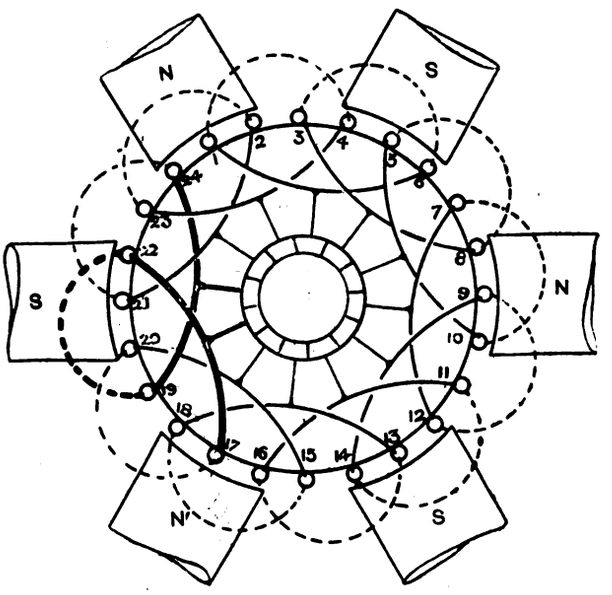

FIG. 8.

From all this it follows that Rule 2 given above for simple multiple-circuit drum windings might be stated as follows:

*Having found the number of inductors that will be required for any particular machine, imagine them numbered consecutively. Take as a forward number-pitch an odd number equal to or slightly greater than* $\frac{w}{p}$, *where* $w$ *is the number of inductors,* $p$ *the number of poles. Call this number-pitch* $y_1$, *then the backward number-pitch is* $y_2 = y_1 - 2$.

*This is the only rule of connection necessary for simple multiple-circuit drum windings.*

**Use of Conventional Winding Tables.**

Instead of drawing out in a diagram such a winding, it is useful to have a conventional form for expressing the arrangement.

These forms are known as winding tables, and there are various methods in use. One of the most convenient is that of placing in a row the numbers of the inductors in order as connected, and then drawing between these numbers lines alternately above and below so that the numbers represent the inductors, the lines the end connections. An example will make this clear.

Example: A four-pole drum-wound machine is to have 114 inductors upon its armature; what will be

Digitized by Google

the winding table for a simple multiple-circuit winding?

We have $\frac{w}{p} = \frac{114}{4} = 28\frac{1}{2}$.

The nearest odd number to this is 29, and we therefore take as the forward number-pitch, $y_1 = 29$. From the rule $y_2 = y_1 - 2$, we have $y_2 = 27$, which gives us the backward pitch.

The winding table will run

1——30——3——32——5——34, etc.

**Drum Armatures with more than One Pair of Inductors per Commutator Section.**

In the case of all large machines the number of commutator sections is half the number of the inductors, or, as it is sometimes expressed, there is one turn (or spiral) per commutator section, exactly as in Figs. 7 or 8. In such cases the winding table above is usually a sufficient guide. It may be that there will be fewer slots in the armature than inductors if a toothed core is used. Of course, the number of slots

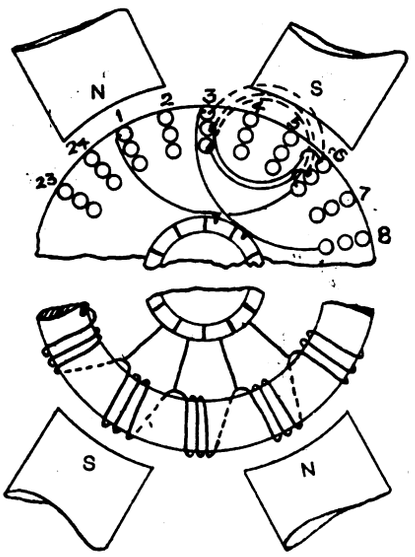

FIG. 9.

must be equal to, or a sub-multiple of, the number of inductors. But this fact will create no difficulty, as in Fig. 8 it is quite easy to imagine inductors 1 and 2 side by side in one slot, whilst 3 and 4 are side by side in the next; or we might have 1 above 2 and 3 above 4 in two slots. In such cases it is better, perhaps, to draw out a slot showing the numbered inductors for the guidance of the winder. The rule given above is in no way altered by these practical considerations, but it is clear in such cases that the *number-pitch* is much more convenient than the distance-pitch used before.

Now, suppose the number of inductors is more than twice as great as the number of commutator sections; we then have a drum armature which corresponds to a ring winding with more than one turn per spiral, such as has been already mentioned. Naturally, by drawing out a case like this in the form of a ring winding and developing the corresponding drum as in Figs. 6 and 7 the whole matter will make itself clear, and will be found to resolve itself into the substitution of a *coil* for a spiral. The total number of inductors must always be a multiple of the number of slots and of the number of commutator sections: and the easiest way of making sure of the connections being regular and correct is first to find the number-pitches, according to the above rule assuming that there are twice as many inductors as sections, and then to substitute for the spiral thus arranged the required number of turns. An example will make this more clear.

An armature of the simple multiple-circuit type is to be arranged with 36 turns (or spirals), and 12 commutator sections for a six-pole field. Give the diagrams both for a ring and for a drum.

According to the method outlined above, we first arrange the ring winding. This is easily done, for it will simply be a ring (like Fig. 6), but with three turns per section, as is shown in the lower part of Fig. 9. The upper part of Fig. 9 represents the corresponding drum winding, which (if we had not already arranged the ring), we should proceed to obtain as follows:

Since there are to be 36 turns on the armature there will be on the drum 72 inductors; and since there are 12 commutator sections the simple drum winding would have 24 inductors with a forward number-pitch of 5 and a backward number-pitch of 3, exactly as Figs. 7 or 8. This gives us the following arrangement, which is shown in the upper part of Fig. 9.

We assume an armature with 24 slots, and there will, therefore, be three inductors per slot, as shown in the diagram. In any case, however many slots there might be, it would still be best to divide for purposes of connection the inductors into 24 *groups*; indeed, in the diagram groups 3 and 4 might be assumed to lie in one slot, 5 and 6 in the next, and so on: this would give us the same number of slots as commutator segments, being probably the most common arrangement met with in practice for small armatures. We number then consecutively the 24 groups, and we know that the connections will be 1——6——3——8. Now multiplying this simplified armature, we start from any group such as that marked 6 and pass to group 3; then *back to group 6*, and continue this process until the inductors of groups 3 and 6 are all joined in. As in this case there are three inductors per group (which corresponds to three complete turns on the armature per commutator section), we shall really wind a little coil of three complete turns when we connect up groups 3 and 6.

When this is finished we pass from the last inductor of group 3 to the first of group 8, and complete 8 and 5 in a similar way to 3 and 6, passing afterwards from the last of group 5 to the first of group 10, and so on.

In the illustration, to avoid confusion, one coil only has been drawn in, and here, as before, the dotted lines represent connections at the back end of the armature. The lower and upper parts of Fig. 9 correspond just as Figs. 6 and 7, and it is immediately noticeable that whereas, in the case of the ring armature, it is almost impossible to wind the coils separately and slip them on the core (because of the armature supports, etc.), yet in the case of the drum armature it is quite possible to wind such a coil as that shown between 3 and 6, bringing out the ends to the commutator, and arranging the shape of the coil so that it will easily clear those wires which lie at 5 and 4.

**Former-Wound Coils.**

This is the foundation of all so-called "former" winding, in which the coil is wound apart from the armature and slipped into the slots afterwards. It is, no doubt, clear that we might have wound the coil between groups 1 and 6, when the connections 6 to 3 would have become the commutator connections, but this would obviously mean waste of armature wire, and in either case if we substitute for every group of three inductors only one, we return to the original arrangement shown in Fig. 8.

Digitized by Google

It is not intended here to go fully into the various shop methods of winding these coils. Full details have been published in many text-books, and we may refer particularly to the excellent illustrations in the last edition of "The Dynamo" (Hawkins and Wallis).

On account of the fact that the connection of the inductors on a multiple-circuit drum gives on analysis the shape shown by the accentuated lines in Fig. 8, such armatures have been termed "lap wound," because after a forward connection there is a "lapping back" to an inductor near the one from which the winding was started. But inasmuch as in all coil windings there must *apparently* be some sort of lapping back, whether lap or wave wound, we prefer here to relinquish, as far as possible, the use of such terms as "lap" and "wave." The examples given should, we think, be sufficient to enable any simple multiple-circuit winding to be arranged or traced out, and without pausing to enter into such arguments as those for or against so-called "chord" winding, excellent examples of which appear elsewhere, we may pass immediately to the consideration of multiplex multiple-circuit armatures.

(*To be continued.*)

## THE LOTS ROAD POWER STATION.

About eighteen months ago we gave a description of the above power station, which was then in course of construction for the Underground Electric Railways Company of London. Now, through the courtesy of the British Westinghouse Company, we are able to reproduce photographs of the completed station, with which the following brief description will be of interest.

The power station (Fig. 1) is situated at the junction of Chelsea Creek with the River Thames, the former of which it bounds on the south, Lots-road running almost parallel on the north side. It is designed to supply energy for working the whole District Railway system and also the Baker-street and Waterloo, the Great Northern and Brompton, the Charing Cross and Hampstead, and the Edgware and Hampstead lines. These in total amount to over 63 miles of track, of which the District Railway supplies about 40, and will unitedly represent by far the heaviest and densest traffic of any electric line. Necessarily, the joining together in one working scheme of so many undertakings, all of considerable importance, has called for a generating station of unusual proportions and design, and the now practically completed Lots-road power-house contains 60,000 h.p. of generating machinery, covers over 3½ acres of land, including yards, etc., and has cost some 2½ millions of money.

The site upon which it stands was formerly occupied by dust destructor and other works, and measures on the water frontage 1,100ft. and on the Lots-road side, 824ft. The size of the building and the plant that it contains has involved the greatest care in laying the foundations, consisting of about 220 concrete piers, and these have been sunk through strata of made ground, gravel, and sand to the London clay at a depth of 35ft. The necessity of making all the excavations watertight as they proceeded was a troublesome and costly one, but the fact that they were well below the river level, even at low tide, made this course imperative. The timber bank or retaining wall of Chelsea Creek was found to be in a very rotten condition, and was replaced by a solid brick wall, which, for some distance, carries the superstructure of the power-house on the south side.

Fig. 2 gives an outline plan of the site and buildings, and it will be noticed that at the eastern extremity a large barge basin is situated, the function of which is to dock the barges conveying coal or other material to the works. Behind this is the oil-cooling plant, and on the western extremity of the site a large bin for containing the furnace ashes before shipment. In the construction of the buildings little less than 20,000 tons of steel have been used, of which some 6,000 tons have gone to the main framework. The chimneys, of which there are four, have now become a recognised landmark to Londoners. They are built on the Custodis principle, with an internal diameter at the base of 19ft. and a height of 275ft., and are placed symmetrically

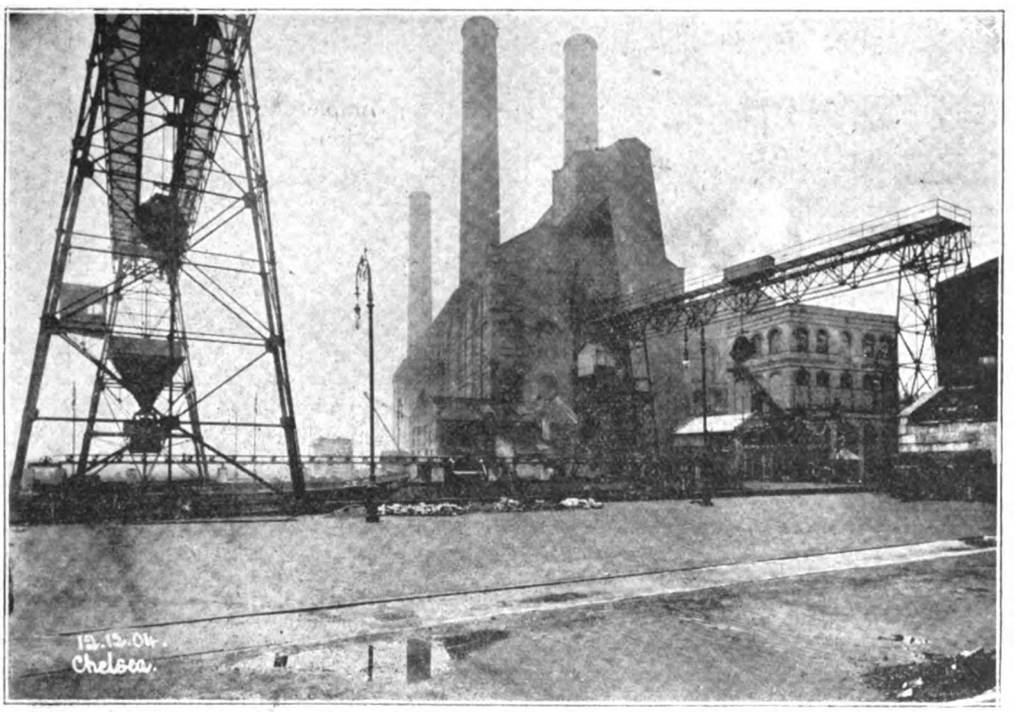

FIG. 1.—Exterior View of the Lots Road Power Station.

in pairs in the boiler-house section, about a quarter of the length of the building from the ends. There are few stacks in Europe that can equal them in size, as they have been designed with a margin for extensions beyond even the present enormous capacity of the station. The internal arrangements of the building, which measures 453½ft. long long by 175ft. broad and 140ft. high, are shown in plan and elevation in Figs. 3 and 4. It will be seen that, as usual, it is divided longitudinally into engine and boiler rooms, the latter of which is the larger, and contains several storeys. The arrangement of the boilers upon two floors is

Digitized by Google

a decidedly novel one in England, but represents almost standard American practice. It has been necessary in the case of the Chelsea power-house on account of the large number of boilers installed and considerations of floor space.

Fig. 4 (the cross-section of the building) shows the coal bunkers situated on the top floor, the capacity of which is 15,000 tons. As the boilers will consume some 800 tons of fuel daily when the station is in full working order, it is

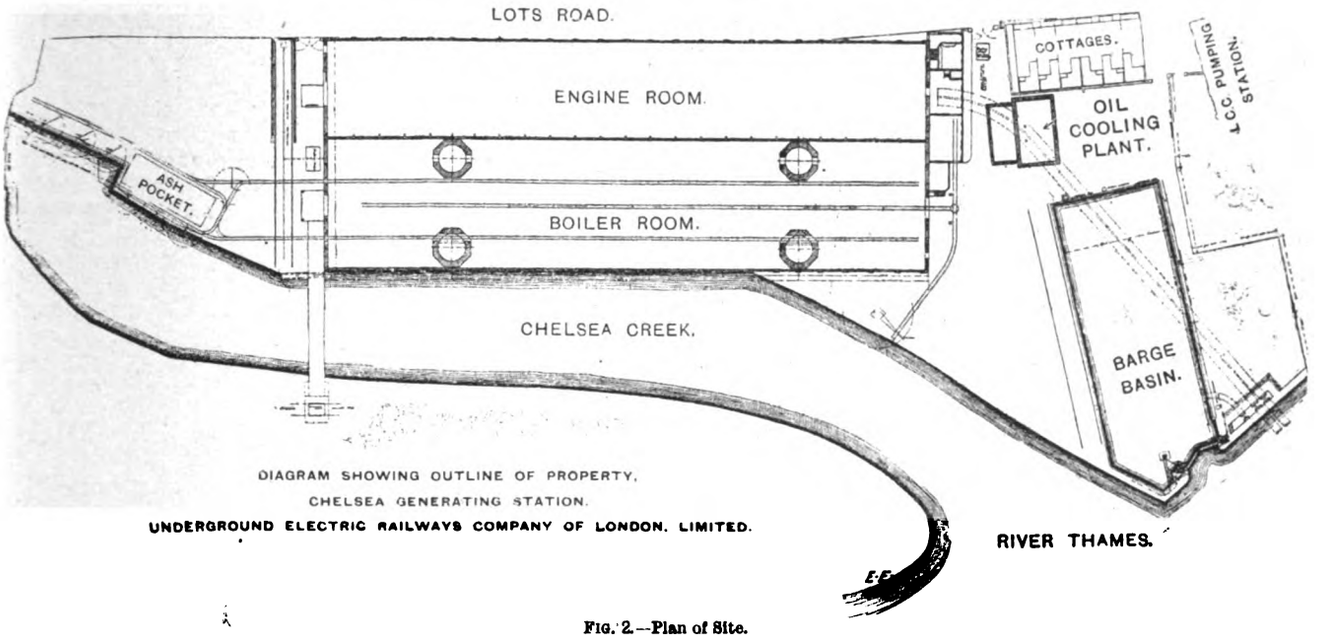

FIG. 2.—Plan of Site.

obvious that such a contents is necessary. The coal is picked up from the barges by two one-ton grab travelling cranes, and after being weighed, is carried by belt and inclined hoppers to the top of the building. Here it is deposited upon another belt conveyor, which is so arranged as to effect its distribution to the several bunkers in any desired quantity. As an alternative to water-borne coal, arrangements have been made to obtain the supply of fuel from sidings of the West London Extension Railway by further arrangements that bring the coal in at the opposite end of the bunkers. The ashes from the fires are dealt with in a most complete way by means of self-dumping buckets that run on rails laid under the ash hoppers on the ground floor. A storage battery locomotive hauls these to the barges, where they are unloaded by pneumatic hoists. Compressed air is used for sundry purposes, including the operation of the barge basin gate machinery, capstans, and sundry large valves in the power-house.

The boiler-house contains 64 Babcock and Wilcox water-tube boilers, supported directly on the steel framework of the building, and space is left for the installation of 16 more. Each possesses 5,212 square feet of heating surface, and is provided with a superheater of 672 square feet area. They are divided up into sets of eight, the number required to operate each turbine unit at full load. There is no steam connection between the various groups except in one case, where a header for supplying steam to the auxiliaries is fed from two of them. Chain-grate stoking gear is provided, with 83 square feet of surface for each boiler. Economisers with 10ft. tubes are grouped behind the boilers with a by-pass flue, as shown in Fig. 4, and the total pipe area installed allows 1,540 square feet of feed-water heating surface per boiler. The main steam-piping runs down the boiler-house side of the dividing wall and under the engine-room floor to the turbines, and is supplied with the usual valves and water-pockets.

In the engine-room (Fig. 5) there are installed eight Westinghouse steam-turbine generating sets, each consisting of a turbine of some 7,300 b.h.p., coupled direct to a three-phase alternator of 5,500 kw. capacity. The former are of the Westinghouse single-cylinder, double-flow type, and are designed to run with a steam pressure of

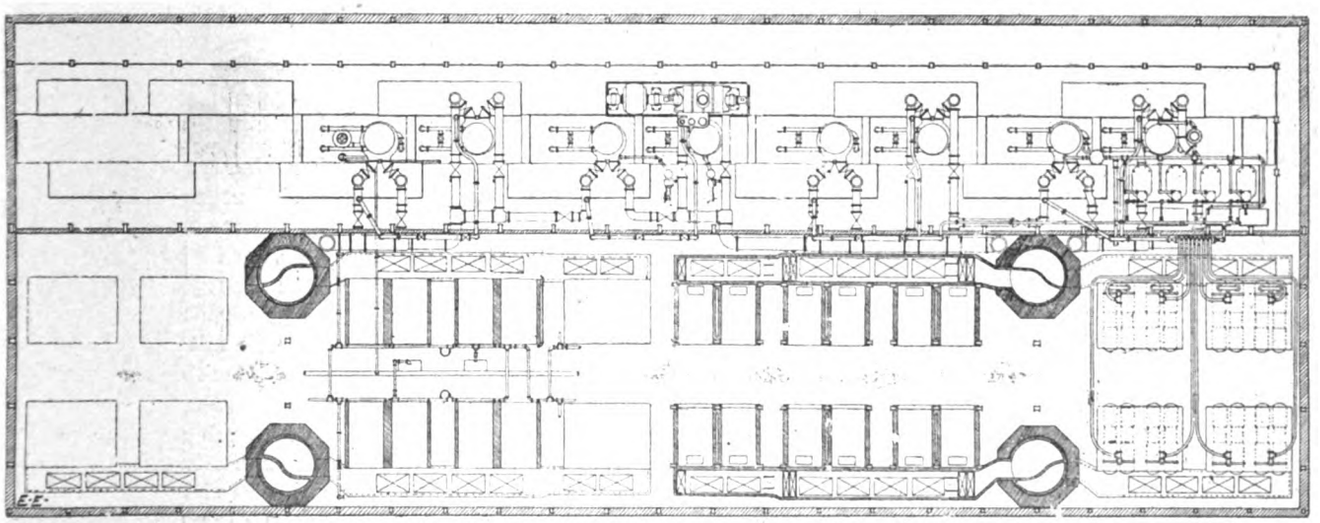

FIG. 3.—General Plan of the Generating Station, showing Steam and Exhaust Pipe Arrangements.

165lb. per square inch, a superheat of 100deg. F., and at a speed of 1,000 revolutions per minute. They are capable of sustaining an overload of 50 per cent. by aid of automatic by-passes, and are extremely economical in steam consumption.

As the Westinghouse steam-turbine differs in many points from others, some details of its construction and operation may not be out of place. The rolled-steel rotating drum to which the blades are fixed is fitted at each end with a forged steel umbrella-shaped disc, shrunk in. The steel shaft is pressed into these, and the result is

Digitized by Google

an arrangement that, though light, is extremely strong. The blades are dovetailed and caulked into grooves cut in the surface of the drum, and are of a special metal in the case of the low-pressure series on account of the corrosive action of wet steam. The main bearings are of the spherical type, and are of cast iron, with Babbitt metal linings. Forged steel flexible claw couplings, running in oil, are provided for connecting the turbine rotors with the revolving fields of the alternators, and are so arranged as to provide for any inexactitude in the alignment of the two shafts.

The course of the steam through the turbine is as follows: Leaving the main disc-type stop-valve, which is actuated by gearing from the platform, the steam flows through an emergency quick cut-off valve, a strainer, and a double-seat poppet governor valve, which latter is operated by a steam relay controlled by the centrifugal governor. It now enters the cylinder at the centre, and, passing through a series of nozzles and impulse blades, expands down to practically atmospheric pressure, continuing then through a number of pressure blades on the Parsons principle to the condenser. The equal flow of steam each way gained by its admission at the centre of the turbine eliminates all end thrust, and therefore the necessity for balance pistons. One end of the shaft is fitted with a thrust block to allow of longitudinal adjustment of the turbine rotor, and a central system of lubrication supplies oil under pressure to each bearing in a separate pipe.

The three-phase Westinghouse alternators are of the revolving-field type, and on a non-inductive load will supply a current of 289 amperes per phase at a pressure of 11,000 volts. They are of 5,500 kw. capacity with a frequency of 33 3 per second. The revolving field is a solid forging of Whitworth fluid-pressed steel of good permeability, and is wound in the usual manner. The armature core of laminated iron is supported by a heavy cast-iron frame, divided horizontally, and is wound in slots on its inner surface.

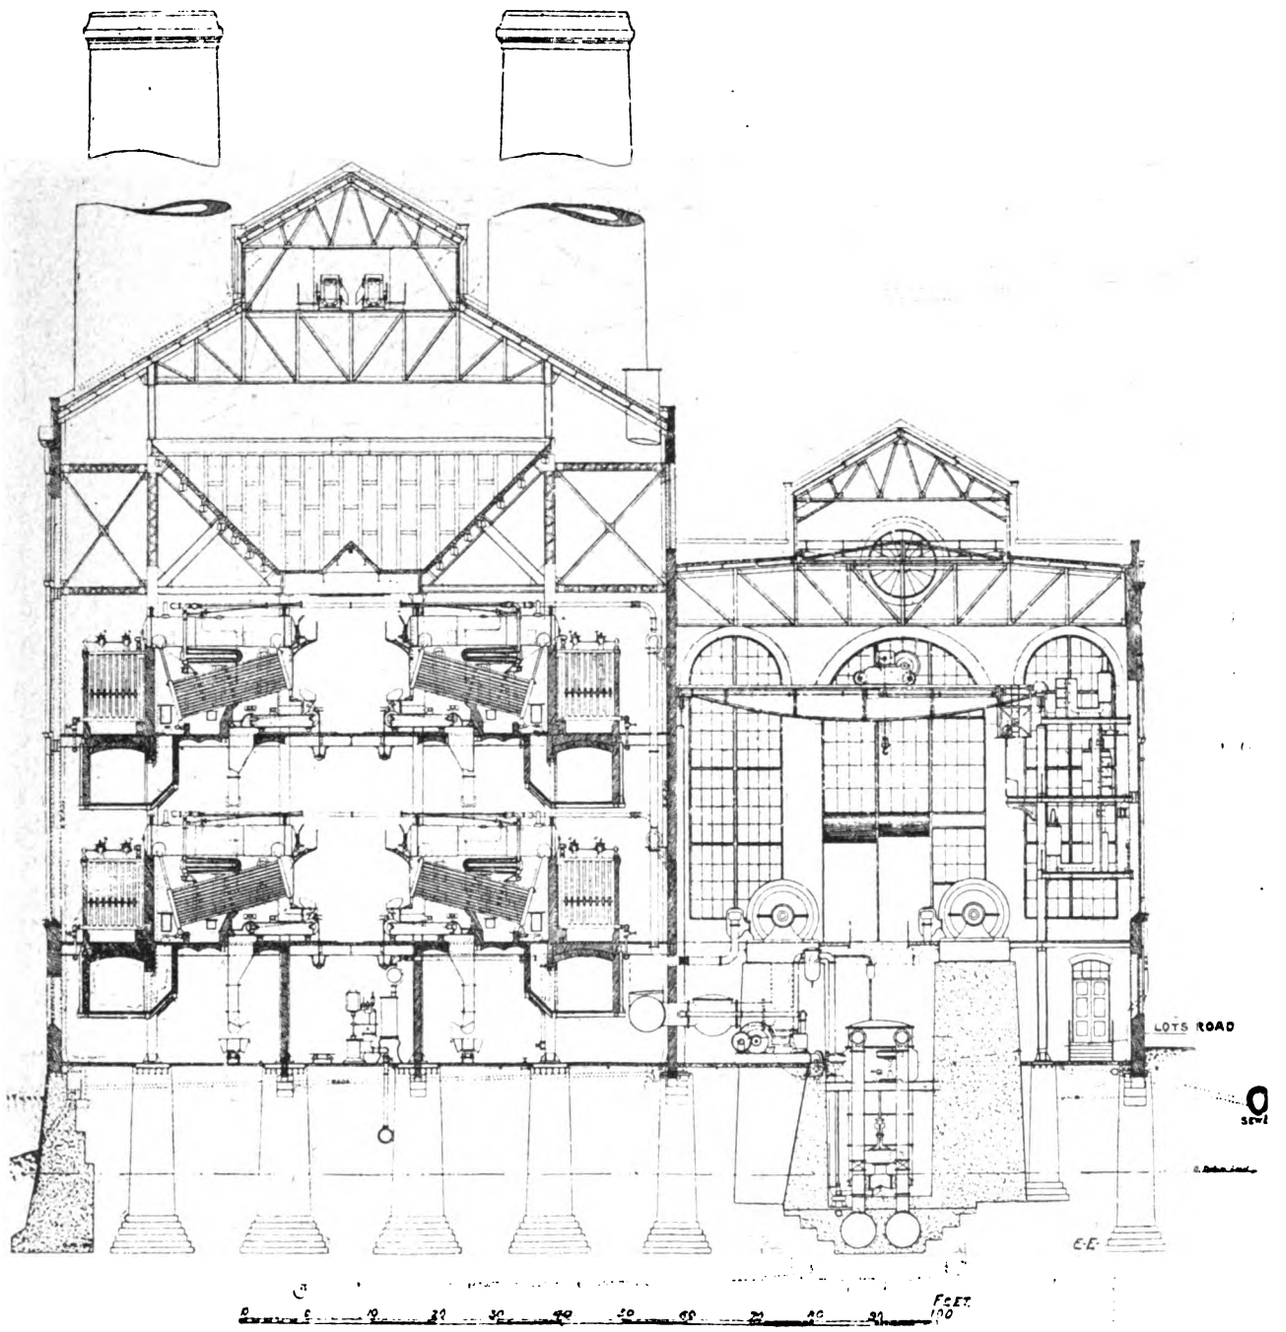

FIG. 4.—Transverse Section through the Engine and Boiler Rooms at Lots Road.

With regard to the auxiliary plant, the four exciter units consist of an Allen-British Thomson-Houston combination, and each have a capacity of 125 kw. at 125 volts when running at 375 revolutions per minute. The condensers are worked on the dry-vacuum principle, with separate motor-driven air and water pumps. They are installed in pits between the two rows of turbines, and have each 15,000 square feet of cooling surface, which is fed with circulating water conveyed through 66in. pipes from the Thames. The water-cooling system is based on the principle of the siphon, and the 20in. centrifugal pumps have simply to overcome the friction in the pipes. The condensing equipment was supplied by Messrs. J. H.

Digitized by Google

Simpson and Co. The switchgear is arranged on three galleries, placed principally across the north side of the engine-room. It was supplied by the British Thomson-Houston Company, and all the high-tension switches are motor-operated by means of a low-pressure circuit con-

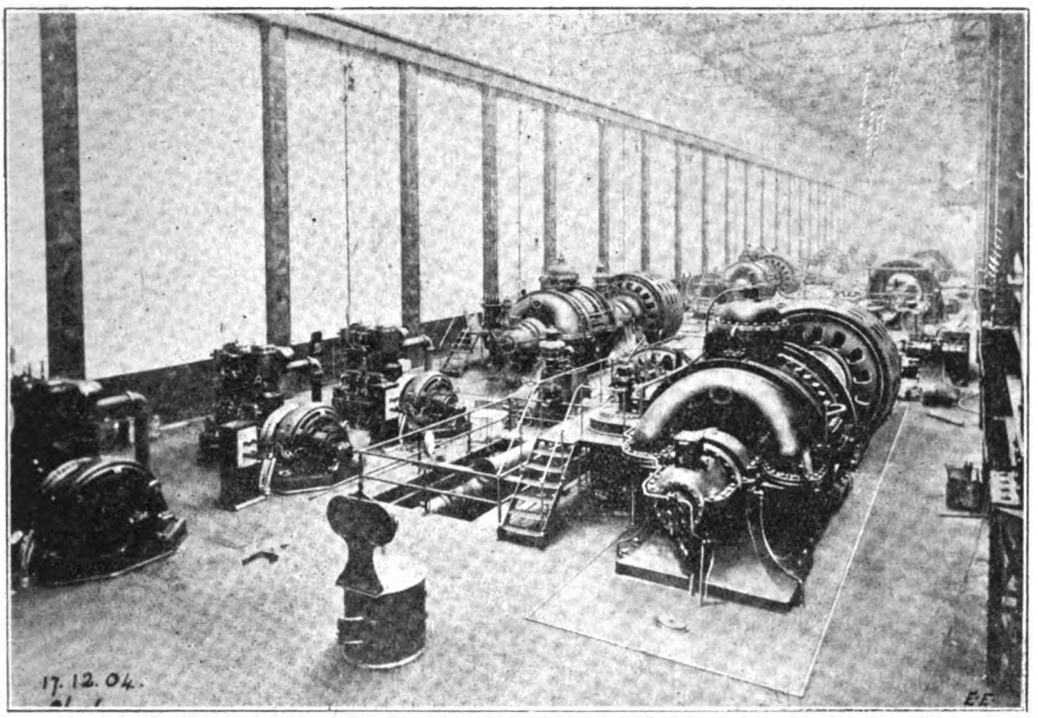

FIG. 5.—The Engine Room at Lots Road, showing 5,000-kw. Turbo-Generators.

trolled from a small pilot switchboard. These were supplied by the British Insulated and Helsby Cables, Limited, and are laid in Doulton stoneware ducts. There are 24 sub-stations on the line, to each of which a duplicate feeder is run; 64 ducts have therefore been laid, which allow for some extension. The feeders are carried through the

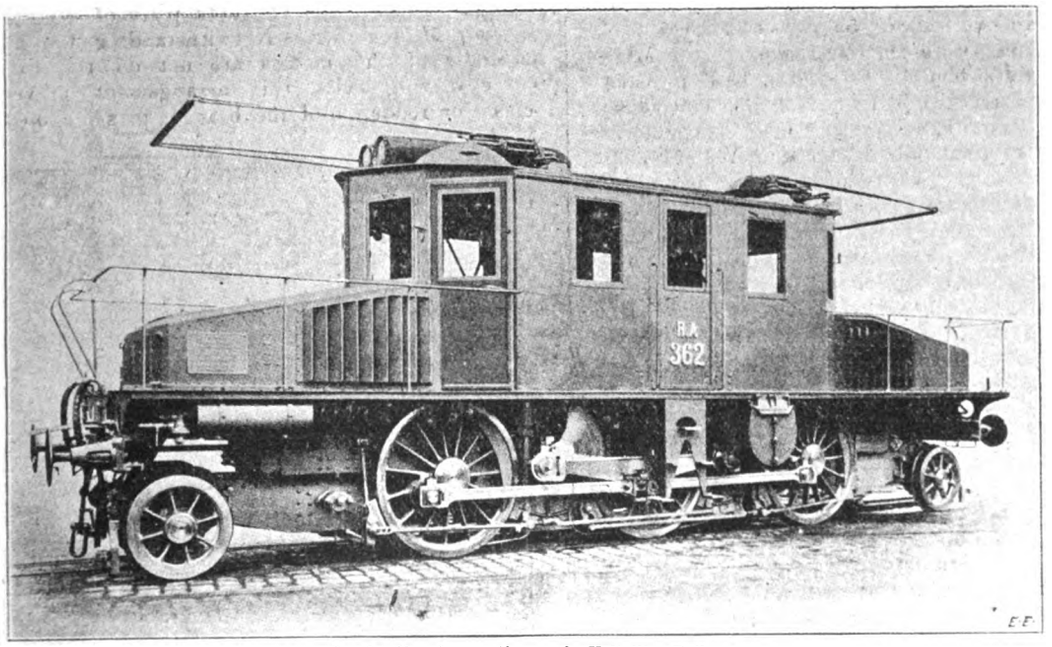

FIG. 1.—New Locomotive on the Valtellina Railway.

streets to the Earl's Court Station of the District Railway, which is the nearest point to Lots-road.

*(To be continued.)*

## NEW LOCOMOTIVES ON THE VALTELLINA RAILWAY.

Some interesting particulars of the new locomotives electrically equipped by Messrs. Ganz and Co., of Budapest, for the Valtellina Railway are contained in an article contributed by Béla Valatin to our contemporary, *Elektrische Bahnen u. Betriebe*. These locomotives are designed to haul heavy trains, and may be said to be the outcome of the great increase of traffic which has taken place since the line was equipped for electric traction, while, at the same time, their design partakes somewhat of the nature of an experiment, in view of the contemplated conversion of the main line Milan-Lecco for electric traction. It was specified that the locomotives should be built for two dominant speeds, the higher to lie between 60 km. and 70 km. and the lower between 30 km. and 35 km. per hour. That they should be driven by polyphase motors, wound for 3,000 volts terminal potential and a frequency of 15, capable of exerting a normal tractive effort of 3½ tons continuously at the circumference of the driving wheels for the higher speed, and of six tons similarly for the lower speed, the drive not to be transmitted from the motors to the axles of the locomotive through the medium of toothed-wheel gearing. It was further required that the locomotives should be able to accelerate a train weighing 400 tons on a gradient of 1 $^{0}/_{00}$ from a position of rest to a speed of

Digitized by Google

30 km. per hour in the space of 55 seconds, or a train of 250 tons weight on the same gradient from rest to a speed of 60 km. per hour in 110 seconds. These accelerations correspond to about 1½ times the normal tractive efforts mentioned in the foregoing. Also that the above results should be obtained notwithstanding a drop in the line pressure from 3,000 to 2,700 volts. Moreover, each locomotive was to be able to start on a gradient of 20 $^0/_{00}$ with a train weighing 250 tons. The motors and other electrical equipment were to be capable of starting a train weighing 400 tons up to a speed of 30 km. per hour on a gradient of 3 $^0/_{00}$ thirty times without undue heating, an interval of two minutes being allowed between each stop and start. A further stipulation was that the motors should be capable of running 10 hours at both the designed speeds, with the above-mentioned normal load, without the temperature of any part rising to more than 60deg. C., and be able to withstand an overload of 100 per cent. for 200 seconds without heating to more than 40deg. C., and an overload of 50 per cent. for a period of one hour. These were the conditions which Messrs. Ganz and Co. were bound by. They had previously designed and constructed a four-axled locomotive with motors coupled coaxially, as in the case of the motorcars and locomotives originally built for the Valtellina line, which have continued to give complete satisfaction to date.

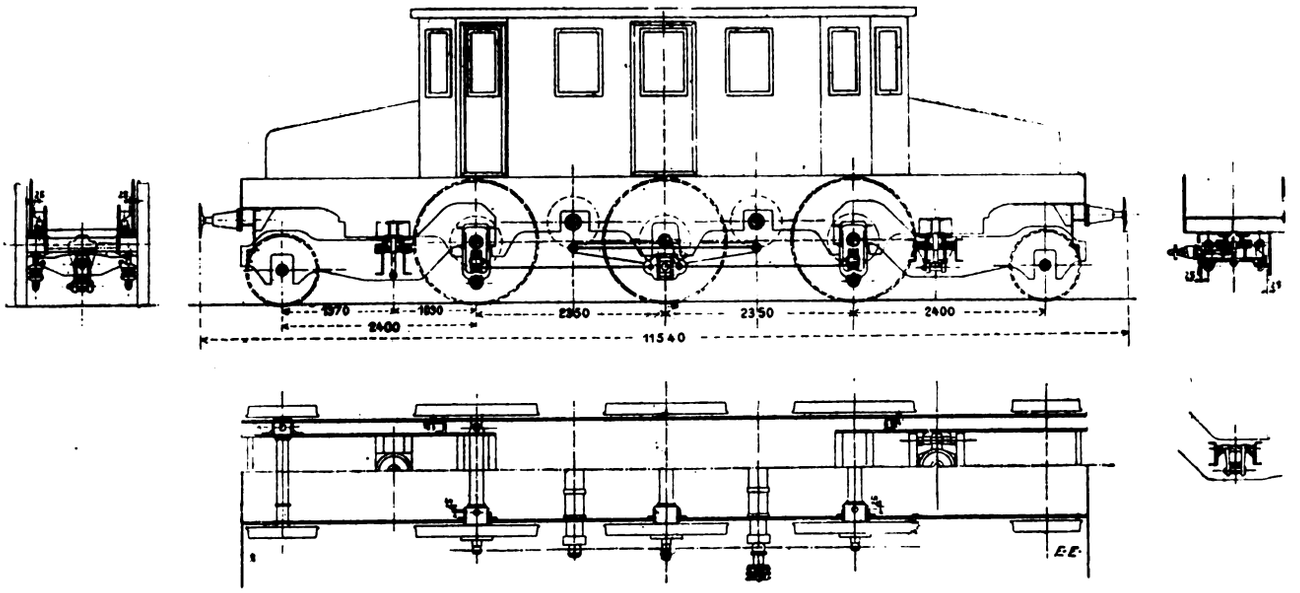

FIG. 2.—Details of New Locomotive on Valtellina Railway.

Each of the new locomotives was to have four motors, two wound for high tension and two for low tension, the latter to be employed only in cascade. The railway engineers did not favour the coaxial arrangement of the motors, despite its advantages. It certainly has the disadvantage that every repair required in the interior of the motor involves the removal of the wheels from the shaft which it drives. The idea of a new solution was arrived at almost simultaneously by the engineers of the Adriatic Railway and Mr. Karl Gölsdorf. This was subsequently elaborated and carried into effect by Messrs. Ganz and Co. and the Hungarian Government locomotive factory, the latter being responsible for the construction of the mechanical parts of the locomotives from designs furnished by the engineers of the Adriatic Railway. Referring to Figs. 1 and 2, the departure which the design marks from the usual practice will be at once seen. It consists in that the motors, although they perform the same number of revolutions per minute as do the driving wheels, are not direct coupled, but placed between the driving wheels, being carried independently by the frame of the locomotive, and driving the wheels through a system of cranks and connecting rods. Thus the motors can at any time be easily detached bodily and replaced. It will be seen from Fig. 2 that the locomotive has five axles in all—three driving axles in the middle and a running axle at either end. The locomotive can be driven at full speed in both directions, and is provided with two drivers' platforms. Its total weight is 62 tons, with 42 tons on driving axles. The extreme length of the locomotive is 11,540mm. (38ft.), the wheel base between each two adjoining pairs of driving wheels being 2,350mm. (7ft. 9in.), and that between an end driving wheel and running wheel 2,400mm. (7ft. 10in.). The diameter of the driving wheels is 1,500mm. (4ft. 11in.) and that of the running wheels 850mm. (2ft. 9½in.). The locomotive is equipped with two double motors, which will be described later on. The power from these motors is transmitted through cranks of 12½in. radius to a driving rod carrying a third bearing in its centre, which in turn is connected with the crank of the middle driving wheel. This bearing is of the peculiar construction shown in Fig. 3, and allows free movement between crank and driving rod in a vertical direction, to relieve any shocks received by the wheel. At either side of this bearing the driving rod is provided with a pivot which engages with one end of a connecting rod, the other end being connected to the crank of one of the two remaining driving wheels. Thus all three pairs of driving wheels are coupled together. Notwithstanding the fact that the shafts of the motors are not on the same level as the driving axles, this arrangement prevents any increase or reduction of the bearing pressure on the rails

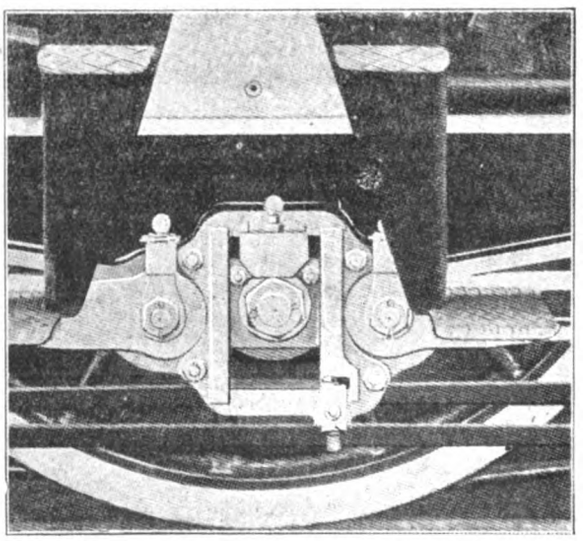

FIG. 3.—Details of Bearing in Centre of Driving Rod.

by vertical components of the driving forces There is an angular displacement of 90deg. between the cranks on the opposite sides of the locomotive so as to avoid a dead centre. It will be seen on referring back to Fig. 1 that the different parts of the system of cranks and connecting rods described are balanced by counter-weights, some of which are cast on the centres of the driving wheels and others bolted to the cranks of the motors. The truck of

Digitized by Google

the locomotive is composed of two main girders of sheet steel construction, with cross braces riveted on. Of the three driving axles only the centre one is allowed no end play, the other two being able to slide in bearings through a distance of about 1in. The truck rests upon two turning centres, which serve as pivots for two bogie trucks of special

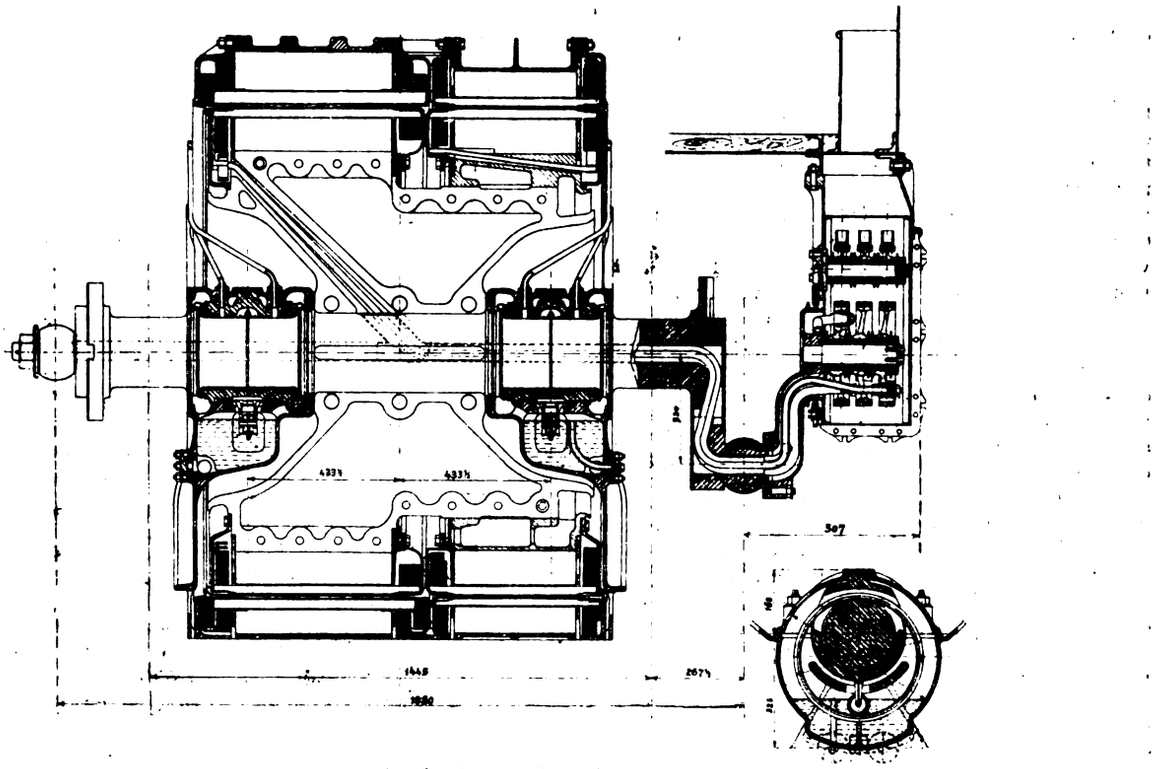

FIG. 4.—Details of Double Motor.

construction. The wheel base of the locomotive is really the distance between the centre driving axle and the centres about which the bogie trucks turn. This type of construction had previously been adopted for steam locomotives on the Adriatic lines with satisfactory results. The transference of the weight on to the bearings of the bogie trucks takes place through the turning centres and longitudinal girders of the trucks, thus ensuring an even distribution of the load.

## ELECTRICAL EQUIPMENT.

Each locomotive is equipped with two polyphase motors of equal power. The special feature in regard to these driving units is that each combines a high-tension motor with a low-tension motor on a common shaft. The low-tension motor is used only in cascade—that is to say, for the slower speeds. On test these motors repeatedly worked up to twice their rated output with a potential drop of 25 to 30 per cent. below the normal. Each side of the combination has eight poles, a synchronous speed of 225 revolutions per minute being attained with the high-tension motor working alone, and 112·5 per minute with the two sides in cascade. The stator windings are arranged as shown in Fig. 4, the separate cast-steel frames which support the respective cores and windings being ribbed externally, and held together by means of a cast-steel ring provided with flanges for bolting through.

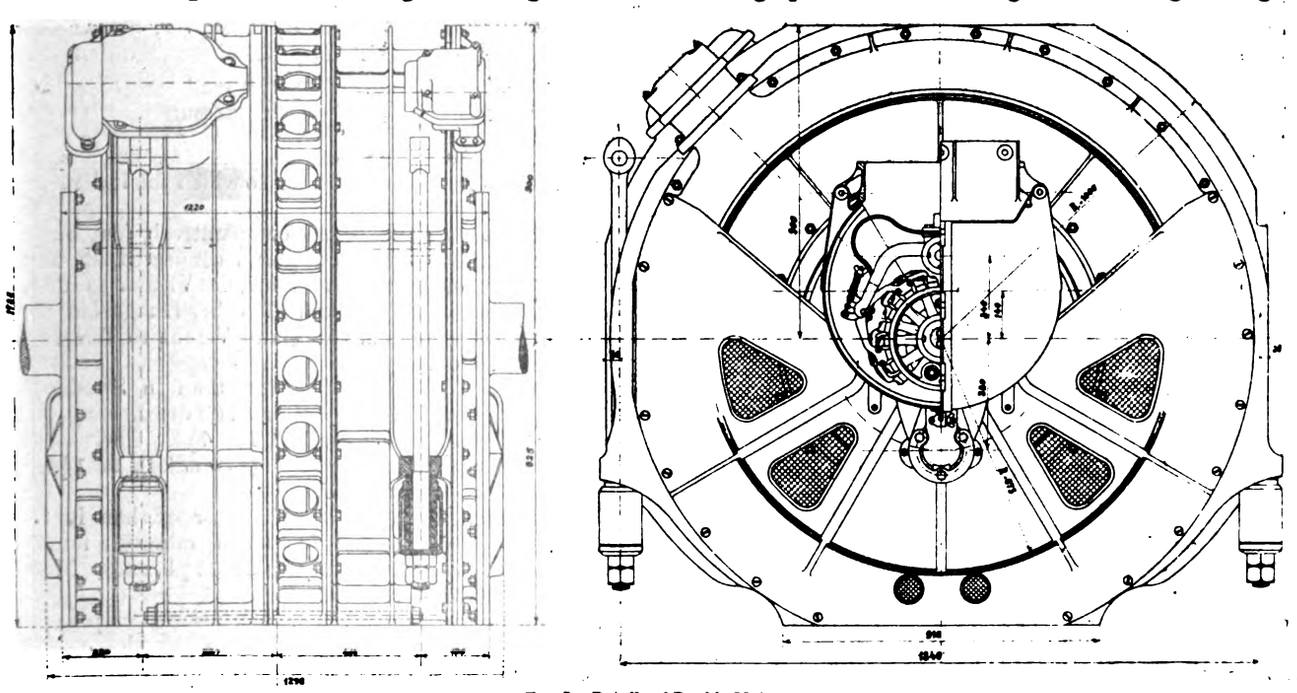

FIG. 5.—Details of Double Motor.

The maximum diameter of the frames is 6ft. 7in., but it will be seen on referring to Fig. 5 that the casing has been cut away in places so as to clear respectively the driver's platform above, the nearest driving wheels at the side, and to come within the minimum clearance allowed between the upper surface of the rails and lowermost portion of the motor. As a matter of fact, so much has been cut away below as to involve not only

Digitized by Google

the ribs and frames proper, but also a portion of the core in each half of the motor. It has, therefore, been necessary to modify the slots and stator windings at this point. The windings are completely boxed in with a metal shield, being thus protected from both damp and oil.

The shaft of the double motor is forged in one piece, with a crank at either end for the two driving rods. In consequence of this, the hub of the motor consists of two parts, which are bolted together. The core plates and rotor windings of the high-tension motor are built up on this hub, but the rotor of the low-tension motor is built up on a special centre and afterwards forced as a whole on to the main hub. The high-tension current is supplied only to the stator belonging to the larger part of the motor, the windings of the second stator, as well as those of the corresponding rotor, being designed for a pressure of 400 volts. The high-tension windings were tested with 15,000 volts, and the low-tension windings with 1,200 volts. The windings of the two rotors are interconnected and protected from damp or oil by metal casings. Each double motor has four bearings. The two inner bearings are supported by cast-steel end plates bolted to the stator, and serve to maintain the rotor in its correct position relative to the stator, which must be exact in consequence of the small clearance in the polyphase motor. Referring to Fig. 4 it will be seen that neither the end plates supporting the inner bearings nor the bearings themselves limit the width available for windings, the distance between the longitudinal girders of the locomotive truck being, therefore, fully utilised for the motor. The method of construction described enables the motor to be detached from the locomotive bodily—that is to say, without dismantling any part. The two outer bearings are carried by the frame of the locomotive. The whole motor is further supported by means of four spring suspension bolts. Spring suspension is necessary, notwithstanding the fact that the outer bearings are rigidly fixed, in order to reduce the shocks due to the mass of the connecting rods and the working of the motor on the track. The details of the inner bearings of the motor are shown in Fig. 4. These bearings are fitted with ring lubricators. The leads connecting the slip-rings and rotor windings are enclosed within the hollow shaft of the motor. Instead of being inside the motor, the slip-rings are arranged outside the frame of the locomotive and driving crank, being attached to a returned crank arm in line with the shaft axis. It may be mentioned that the whole crank is made hollow to contain the connecting leads. There are only three slip-rings to each double motor, since the two rotors are permanently connected together. These slip-rings are used when the high-tension motor is working alone; they are not required when the two motors are in cascade.

The brush-holders are enclosed in a wrought-iron box which covers the crank extension. This box is suspended from the truck of the locomotive. The two parts of which it consists are hinged so as to enable ready access to the brushes at any time. Carbon brushes are used.

*(To be continued.)*

## TELEPHONE TRUNK-LINE CHARGES.

BY ALFRED R. BENNETT, M.I.E.E.

In my article on Jan. 6, on "The Proposed Telephone Deal," I remarked that as the trunk lines have practically been paid for twice over, it is not surprising that the Post Office finds it necessary to charge trunk rates about twice or thrice the amount levied by Continental telephone administrations. I made that statement on information gleaned several years ago, and in order to be sure that no change has occurred since, I communicated last month with the British consuls in the various European capitals, and from information supplied by them have satisfied myself that the statement still tallies with the facts. It even seems that in using the words "twice or thrice" I was guilty of an under-estimate, for it now appears that British Post Office charges are sometimes even four or five times as high for corresponding distances as some of the Continental ones. In Germany the trunk-wire system has received very great extension, and the present tariff is, for three-minute talks:

| | s. | d. |
|---|---|---|
| Up to and including 15 miles | 0 | 2½ |
| ,, ,, 31 ,, | 0 | 3 |
| ,, ,, 62 ,, | 0 | 6 |
| ,, ,, 310 ,, | 1 | 0 |
| ,, ,, 621 ,, | 1 | 6 |
| Exceeding 621 ,, | 2 | 0 |

This covers the whole of the German Empire, and as distances are long it is obvious that the telephone trunk system is exploited with an eye to the benefit of the commercial needs of the country. A German merchant or manufacturer can talk from Berlin to Memel (400 miles), or from Frankfort to Danzig (535 miles), or from Aachen to Hamburg (500 miles) for 1s. 6d.; or from Aachen to Memel (740 miles) for 2s. The same distances in Great Britain would cost from three to four times these amounts.

In France the trunk-line tariffs are based upon the distances between Paris and the various departments, and for three-minute talks work out as follows:

| | s. | d. |
|---|---|---|
| 40 miles | 0 | 4 |
| 100 ,, | 0 | 4½ |
| 200 ,, | 0 | 9½ |
| 260 ,, | 1 | 2½ |
| 377 ,, | 1 | 7 |
| 435 ,, | 1 | 9½ |
| 453 ,, | 2 | 0 |

One can talk from Paris to Lyons (250 miles) for 1s. 2½d., to Bordeaux (310 miles) for 1s. 5d., and to Marseilles (420 miles) for 1s. 9½d. The highest charge is from Paris to the Pyrénées-Orientales—2fr. 50c., or 2s. The corresponding British charge would be from 3s. 4d. to 5s. 6d.

Distances are very long in Sweden, but the trunk-line tariff is very cheap. Three-minute talks are charged as follows:

| | s. | d. |
|---|---|---|
| 25 miles | 0 | 1½ |
| 110 ,, | 0 | 4 |
| 260 ,, | 0 | 6½ |
| 380 ,, | 1 | 1 |
| 490 ,, | 1 | 7½ |
| 620 ,, | 1 | 11 |

In England three-minute talks from London to Birmingham or Nottingham cost 1s. 9d. In Sweden, corresponding distances, say Stockholm to Orebro, cost 4d. London to Dublin (491 miles) costs 7s.; Stockholm to Haparanda (525 miles), 1s. 11d.; London to Edinburgh (340 miles), 4s. 6d.; Stockholm to Umeä (335 miles) 1s. 7½d.

In Italy one can speak from Rome to the principal towns for 1s. 2½d. up to 150 miles (Rome to Florence), and for 1s. 7d. up to 380 miles (Rome to Messina), which appears to be about the greatest distance to which the Italian trunk lines reach.

In Austria trunk lines are comparatively few, but you can speak to the most distant places connected, about 220 miles, for 2s. 6d. for three minutes. Vienna to Prague, Cracow, Fiume, Budapest, and all other Hungarian towns costs 1s. 10d. for three minutes, and Vienna to Trieste (220 miles) costs 2s. 6d.

In Norway distances are shorter than in Sweden, the longest trunk lines being from Christiania to Levanger (265 miles) and Namsos (315 miles), 1s. 4½d.; Christiania to Stavanger (180 miles) and Bergen (175 miles), 1s. 1¼d. The shorter distances cost from 3½d. to 6½d.

In Russia trunk charges are also cheaper than in Great Britain, for one can talk for three minutes from St. Petersburg to Iver (298 miles) for 2s. 11½d., and to Moscow (402 miles) for 4s. 4d.

In the smaller countries the distances are comparatively short. Over the longest lines in Denmark the charge is 1s. 8d. for three minutes; over the shorter much less. One can talk all over Belgium for 1fr. (9½d.) for three minutes. In Holland 10d. for three minutes is the maximum charge. In Switzerland I cannot find that any fee exceeds 7½d. for three minutes, while most of the towns can be spoken between for 30 centimes or 50 centimes. Between Berne and Zürich (60 miles) the charge is 4½d., and from Berne to Geneva (80 miles) 7½d.

For the purpose of contrasting the great difference between the British Post Office charges and those in the larger countries named I have constructed the accompany-

| From London to Birmingham | 105 | 1 6 | 0 3 | 1 9 | 1 0 | 0 4½ | 0 4 | 1 2½ | — |
| From London to Nottingham | 110 | 1 6 | 0 3 | 1 9 | 1 0 | 0 4½ | 0 4 | 1 2½ | — |
| From London to Manchester | 165 | 2 0 | 0 4 | 2 4 | 1 0 | 0 7½ | 0 6½ | 1 2½ | 1 10 |
| From London to Swansea | 170 | 2 0 | 0 4 | 2 4 | 1 0 | 0 7½ | 0 6½ | 1 2½ | — |
| From London to Liverpool | 180 | 2 0 | 0 4 | 2 4 | 1 0 | 0 9½ | 0 6½ | 1 7 | — |
| From London to Plymouth | 200 | 2 6 | 0 4 | 2 10 | 1 0 | 0 9½ | 0 6½ | 1 7 | 1 10 |
| From London to Newcastle-on-Tyne | 260 | 3 0 | 0 4 | 3 4 | 1 0 | 1 2½ | 0 6½ | 1 7 | 2 6 |
| From London to Edinburgh | 340 | 4 0 | 0 6 | 4 6 | 1 6 | 1 7 | 1 1 | 1 7 | — |
| From London to Glasgow | 365 | 4 6 | 0 6 | 5 0 | 1 6 | 1 7 | 1 1 | 1 7 | — |
| From London to Dundee | 377 | 4 6 | 0 6 | 5 0 | 1 6 | 1 7 | 1 1 | 1 7 | — |
| From London to Belfast | 404 | 5 6 | 0 6 | 6 0 | 1 6 | 1 9½ | 1 7½ | — | — |
| From London to Aberdeen | 436 | 5 0 | 0 6 | 5 6 | 1 6 | 1 9½ | 1 7½ | — | — |
| From London to Inverness | 453 | 5 6 | 0 6 | 6 0 | 1 6 | 2 0 | 1 7½ | — | — |
| From London to Dublin | 491 | 6 6 | 0 6 | 7 0 | 1 6 | — | 1 7½ | — | — |
| From London to Cork | 619 | 8 0 | 0 6 | 8 6 | 1 6 | — | 1 11 | — | — |

ing Table A. It must be understood that there are no terminal charges on the Continent, but such a large proportion of trunk-line calls made in Great Britain are subject to terminal fees that in order to make a proper comparison it is necessary to include the terminal charge with the trunk-line charge, and this has accordingly been done. Up to 100 miles the table gives the comparative tariffs on distances alone; above that distance the British charges between London and the chief centres in the United Kingdom are first given, followed by the foreign charges for corresponding distances.

It is necessary to mention that in some of the Continental countries the already moderate rates are considerably reduced after business hours. Thus in Holland the 10d. rate applies only between 11.40 a.m. and 3.40 p.m.; for the rest of the day it is only 5d. In Denmark the rates are reduced by about one-third between the hours of 6 p.m. and 9 a.m. and all day on Sundays and holidays.

The result of my investigations is to thoroughly confirm the opinion that the British trunk telephone service is by very far the most illiberal in Europe. It even dawdles behind Russia. To what must we ascribe the fact? Why should the department to which the telegraphs were confided, in order that they might be worked for the benefit of the community, impose such an unwarrantable tax on British industry—such a strong restraint on the trade of the country? The trunk lines between all the great English and Scotch centres ought to be kept humming with commercial and industrial traffic, as those on the Continent are, but the rates are so prohibitive that the longest lines are used almost exclusively by stockbrokers, who alone can afford them. The answer is, I apprehend, three-fold: (1) the existing trunk lines have cost the Post Office at least twice, and probably three times, their real value considered as plant; (2) the expensive methods of working characteristic of the Post Office; (3) the desire to protect telegraphs, as distinguished from telephones—*i.e.*, to defy and work against the law of the survival of the fittest. For the purpose of hampering telephone development the Post Office got the telephone declared a telegraph, but now that the telephone challenges the supremacy of the telegraph for long distances, a new attitude is assumed—that they are not only distinct but hostile units, one of which must be suppressed as far as possible in favour of the other. It is not seen that it would pay to encourage the use of long telephone lines, as is done on the Continent. Probably, if they were asked, the Post Office officials would say that a 6d. telegram from London to Glasgow, Aberdeen, or Dublin does not pay, and that the State loses on every one dispatched. They would probably agree that a 6d. telegram rate pays up to 100 or 150 miles, after which every message represents a loss; but if the telephone rate from London to Glasgow, etc., were 1s. 6d. for three minutes (as for the same distance in Germany), they could afford to lose three 6d. telegrams for every telephone call. These calls would multiply exceedingly, and in the end the revenue earned would very likely be larger from telephone calls than it now is from telegrams. This is how it works out on the Continent, for it is impossible to believe that Continental governments, even the Russian, continue year after year to work their telephone trunk lines at a loss. Such a contingency is inconceivable, because they *all* are cheap, and only the British is dear. If one or two only were cheap it might be suspected that they were so from some special reason, such as subsidising intercommunication for commercial purposes within their own borders. But all are not likely to be smitten by the same fad. If the Continental rates are not only low, but sufficient, given good management, then the existing state of matters in Great Britain amounts to nothing less than a scandal. As I stated in my former article, there is great danger of the excessive charges made for trunk communication finding a counterpart in local telephone rates if the Post Office is allowed to purchase the National Telephone Company without proper supervision and without proper enquiry in advance as to probable results. Surely this trunk-line fiasco is an object lesson which cannot be ignored.

## CROYDON PUBLICITY DEPARTMENT.

In our issue for Jan. 20 we announced that Mr. G. R. Pepper had been appointed head of the publicity department in connection with the electricity supply system of Croydon. Through the courtesy of Mr. Alex. C. Cramb, the borough electrical engineer, we are now able to give full details of the work which will fall to this department, and the importance of which cannot be over-estimated. In those electrical supply undertakings where there is no opposition, the engineer and manager is apt sometimes to disregard the feelings of the consumers and to treat them in an autocratic way, which does much harm to the undertaking. We know of instances in which the dissatisfaction arising from such treatment has led to a great falling off in the demand, which could have been prevented had some such department as that now organised by Mr. Cramb been instituted. It is not enough nowadays for the supply undertakers to give a supply as authorised by their provisional orders, but they must also ensure that they give such satisfaction to the consumers that rival illuminants and suppliers of power are fought on at least equal terms. The expert supervision which the new Croydon department will exercise over the working of consumers' apparatus is one point greatly to be commended, and we trust that the vexed question of the quality of incandescent lamps used will be gone into as thoroughly as the adjustment of arc lamps. At first there may be a few of the

Digitized by Google

local contractors who may object to the department in question, but in the long run it will assist these contractors quite as much as it will the Croydon consumers. The following is Mr. Cramb's letter to us explaining the lines on which the department is organised. We wish every success to this new departure.

"Dear Sir,—In reply to your letter of the 18th inst., the reason why I propose starting a separate publicity department is the evident necessity of the business of a supply company or corporation being sufficiently pushed. If a firm sells any line of goods, they do not expect to do a large business unless they put travellers on the road who bring before the people the advantages of same, and, in a similar way, a supply company or corporation which is anxious to sell electricity should, it seems to me, adopt a similar course. In those places, such as Durban, where there is no rival illuminant, the engineer has merely to order more plant to meet the increasing demand, but where one has a rival illuminant, which is very actively pushed, it is only by proper organisation and advertisement that there can be a hope of increasing to any considerable extent the business after the first rush of consumers have been connected.

"The lines upon which I intend eventually to run this department are somewhat as follows: There will be a departmental head, the same as in the other departments, who will deal with the question of present and prospective consumers. He would either personally, or by means of his staff, keep in touch with the consumers, and take in hand any complaints there may be made from time to time, as not only would new consumers be gained, but the present consumers would be kept in a state of content, and thereby kept from reverting to a rival illuminant. The gas company have found it good policy to inaugurate such departments; these departments have gone on somewhat similar lines to those indicated, and what has been found satisfactory with gas should undoubtedly be satisfactory with electricity.

"The manager of an electric supply undertaking, of course, relies to a certain extent, on the contractors, and in working harmoniously with them a considerable amount of business can be obtained. On the other hand, there are, unfortunately, contractors who, either from lack of knowledge or want of foresight, do not trouble to see that their customers are left in a satisfied and satisfactory condition. For instance, I received a complaint about certain arc lamps belonging to a consumer in this town that they were very costly. A casual examination of these lamps showed that they had been left by the contractor working with 15 amperes, instead of 10 amperes as they were rated. By sending one of my men to adjust these lamps, and reducing the current consumption, the noise which was previously quite noticeable ceased, the light was just as satisfactory, and the cost was a great deal less. It is these cases that the manager of a publicity department might be able to take in hand, and often prevent the loss of a consumer. It seems to me that every electric light undertaking which can possibly afford it should run a showroom, and this, of course, would be the headquarters of the publicity department. Exhibitions should, moreover, be held from time to time.

"The manager of a municipal undertaking is much handicapped from doing many things in furthering the business for which he is responsible owing to the questions of municipal trading and jealousies of the local contractors. I think it is a great pity that there is not a better understanding between the contractors and the supply companies. The interests of the two are, in the main, identical, and every contractor who does good work and shows proper consideration to his customers must be considered by the manager of a supply company as a friend and a helper in the promotion of his business.

"Among the contractors who have been properly trained as electrical engineers, and understand fairly well the connection of their work, there seems very little difficulty in working in harmony; but it is the men who have taken electrical work as an auxiliary to their main work, and who have not been trained thoroughly, who seem to look upon the supply manager as someone who is anxious to interfere with their business.—Yours faithfully,

"ALEX. C. CRAMB, Borough Electrical Engineer."

## BIRMINGHAM LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

On Jan. 25 Dr. D. K. Morris, associate member, read an interesting paper, fully illustrated by lantern slides, on "The American Visit of the Institution of Electrical Engineers," of which the following is an abstract. The first portion of the paper consisted of a brief outline of the tour. The Institution party landed at Boston, and proceeded to St. Louis *vid* New York, Schenectady, Montreal, Chicago, and Springfield. After about a week's stay at St. Louis, the party returned to New York, visiting *en route* Pittsburg, Washington, and Philadelphia. At each of these towns they were met by a local committee of the Institution of Electrical Engineers, who received them most cordially. No pains were spared or cost stinted. The hand-books which were presented to each member by the local committee contained a guide to the city, and a detailed description of all the electrical undertakings to be found there.

Proceeding to technical details, the author first dealt with central stations having steam generating sets. Of these they saw a large number, more especially in New York. This city possesses five huge central stations, in addition to a number of smaller ones in outlying parts. The former are: (1) The "Waterside," or Thirty-eighth-street station of the Edison Company, built for an output of over 75,000 kw. This station deals with most of the lighting of the city on the 110-volt three-wire system. (2) The Ninety-sixth-street station of the street railway or tramway system of 40,000 kw. (3) The Kingsbridge station, also working mainly on tramway load, and capable of an output of 30,000 kw. (4) The Seventy-fourth street station, which supplies the power which operates the New York Elevated Railroad. This is found to require at times a total of 50,000 kw., which is at least 5,000 kw. in excess of the station capacity. This excess is provided by the Fifty-ninth-street station. (5) The Fifty-ninth-street station was built to supply power to the recently opened New York Subway, and equipped with plant of more than 50,000 kw. capacity. A station of 60,000 kw. ultimate output is also being equipped in Brooklyn. The above shows the enormous demand for electric power in New York. Boston and Chicago have each two stations of similar output, and other great cities are proportionally equipped.

The standard size of unit is 3,500 kw. in the older to 5,000 kw. in the newer stations. A temporary overload capacity of even 50 per cent. on these figures is occasionally demanded. The generators are alternating current and wound three-phase for 6,600 or else 11,000 volts, speed 70 to 75 revolutions per minute, frequency 25. The maximum efficiency of such generators is high—over 97 per cent. The engines are largely of the vertical cross-compound condensing type with Corliss gear. In some cases the two high-pressure cylinders were placed horizontal and the cranks at 135deg., thus securing eight impulses per revolution. This facilitated parallel running. In most of the newer stations steam-turbines and high-speed alternators are being put down. Many stations obviously designed and built for large slow-speed engines had been installed with turbine sets. Stations designed at the outset for vertical-shaft Curtis turbines were, however, to be found at Boston and Chicago. Here the standard turbine set was of 5,000 kw.; output, 500 revolutions per minute. The floor space occupied is less than half that of one of the old 1,500-kw. slow-speed engine sets. In Boston the turbine-generators were three-phase, 7,500 volts, 60 cycles.

Beside the Curtis turbine, which is manufactured by the General Electric Company at Schenectady, the British Westinghouse Company do a large business in the Parsons type. The author had, however, gained the impression that the small vanes and high speed of the latter did not lead to such good results as with the Curtis type.

The most noticeable feature in connection with the switchgear was the motor-operated high-tension switch. It was common practice to place these switches in a separate building, in order to minimise fire risks. Small direct-current motors are used to compress springs which open and close the main switches. The motors themselves

Digitized by Google

are controlled from the generating station, the switchboard for the purpose being frequently arranged on a sloping table. A red or green light shows whether the main switches are on or off. The relay motor may be supplied either from the exciting circuits or off a special 110-volt battery. Sub-stations are usually equipped with 1,000-1,500-kw. rotary converters running at 115 revolutions per minute, and having an efficiency of about 97 per cent., to suit which the pressure is transformed down to 175 volts. Sub-stations were usually provided with batteries.

Dr Morris then described the central stations visited in which water power was used. These were at Niagara and Shawinigan. The large and now well-known stations on the American side of the Niagara Falls are small when compared with the vast schemes on the Canadian side. (1) The Canadian Niagara Falls Company are building a 110,000-h.p. station; (2) the Electric Development Company, of Ontario, one of 125,000 h.p.; (3) the Ontario Power Company is starting a 135,000-h.p. scheme. The greater portion of this power will be taken by Toronto, 60 miles distant. The pressure of transmission is to be 60,000 volts. The lesser known falls at Shawinigan proved fully as interesting to the party as did Niagara. The power station is situated at the foot of the falls, and is of 30,000 h.p. capacity. Directly above the station, at the head of the falls, is a large aluminium works, to which low-tension direct current is supplied, two sets of aluminium rods of 22 square inch combined section being used for the short transmission. With the exception of this direct-current set the generators are two-phase 2,200-volt Westinghouse and Dick-Kerr types. The current is transformed, as in the older stations at Niagara, to three-phase by means of Scott connected transformers. The power is transmitted at 50,000 volts to Montreal, 83 miles distant. There are three $^{7}/_{7}$ aluminium wires, 60in. spacing, the pressure drop being 18 per cent. for 5,000 kw.

The author then dealt with electric traction methods, mentioning many interesting details. He was much struck by the amount of time and labour that the firms in America were devoting to the single-phase traction problem.

In conclusion, he considered that in nearly every case the greater advances made in electrical engineering in America compared with this country were due to the larger scale upon which necessity compelled them to work. The presence of ample water power great distances from the large industrial centres gave rise to large power long-distance systems of transmission. Their traction schemes were on a large scale. There were disadvantages in connection with the possession of such large organisations as the General Electric and the Westinghouse Companies There was a tendency to retain well-tried but partially obsolete methods, the persistence of two-phase plants in certain types of installation being a case in point. There were, however, many advantages, the most real being the enormous resources which can be directed to the development of great new problems, such as the perfection of the steam-turbine, the improvement of single-phase traction methods, and the working at the highest voltage limits in power transmission.

The following is a brief abstract of the discussion:

**Mr. Vaudrey** called attention to the immense size of all the electrical undertakings mentioned. Stations having a capacity of 100,000 h.p. could not be approached in this country. The combined capacities of London, Manchester, and Birmingham could scarcely touch it. It seemed to show that there was still an immense field open for electrical undertakings in this country.

A second speaker asked Dr. Morris for information as to the average charges for lighting and power made by the large supply companies.

**Mr. Taylor** asked for information as to the length of time which the 50 per cent. overload mentioned by the author could be maintained. The efficiency figure of 97 per cent. seemed high. He understood from descriptions of recent tests made on large sets in New York that the maximum figure reached was 96 per cent. He would like to know if the exciting current had been included. The frequency of 60 cycles per second mentioned in connection with turbine sets seemed to him excessive. He would like to know what was being done in the way of using rotary converters for lighting work in America. With reference to the use of batteries in sub-stations, he had not gathered whether the sub stations referred to were those of the Edison Lighting Company or of the large power companies. Was the battery used for night supply or to take up the peak of the load?

**Mr. Groves** asked Dr. Morris if he could give any reason for the continued use of 110-volt direct-current supply for lighting.

**Mr. Holden** would be glad of information as to the types of meters used in America. We have American-made alternate-current meters over here, but none for direct current.

**Dr. Morris**, in replying, said that the price at which current was supplied for lighting in America was often comparatively high—about 6d. to 8d. per unit. But for power it was about 1½d. per unit, leaving out of consideration exceptional cases like Montreal, where, subject to a restricted hours' clause, the charge did not work out to more than ½d. per unit. In connection with prices, however, it should be remembered that the purchasing value of money was about two-thirds that of the same amount in this country. That probably accounted for the high rate. In reply to Mr. Taylor, the 50 per cent. overload capacity he had mentioned was not specified to be maintained for any long period. It might safely be applied for five to ten minutes. The efficiency figure of 97 per cent. was for a very large generator. At 25 per cent. overload the efficiency was 97·2 per cent. Sixty cycles per second was the frequency of the generators for the lighting system at Boston, but the actual lighting was mostly direct current. Twenty-five cycles was the standard for the alternating-current transmission. When talking of the employment of batteries in sub-stations he had considered it more in connection with lighting than power. They were usually kept floating on the mains, and were thus used for the peak load. In reply to Mr. Groves, there were fairly good reasons for retaining the 110-volt system of supply for lighting. It had established itself as the standard voltage of the Edison combination. When the supply companies introduced high-tension alternating-current transmission, they found it as easy to transform down for 110 volts as for 220. The closeness of the converter sub-stations, due to the congested districts supplied, brought the areas well within the range of 110-volt distribution. In reply to Mr. Holden, the Edison illuminating companies used the General Electric Company's watt-hour meters almost exclusively. Quantity meters were very little used, if at all.

**Dr. Sumpner** (chairman) then moved that the cordial thanks of the meeting be accorded to Dr. Morris for his interesting and instructive paper.

## FORTHCOMING EVENTS.

FRIDAY, FEB. 3.

**Junior Institution of Engineers.**—At 8 p.m., "Recent Developments in Electric Lighting," by Prof. H. T. Davidge.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "The Electric Equipment of Automobiles."

SATURDAY, FEB. 4.

**Institution of Electrical Engineers (Glasgow Section).**—At 7.30 p.m., annual smoking concert at the Grosvenor Restaurant, Glasgow.

**Institution of Electrical Engineers (Students' Section).**—Visit to Messrs. Evershed and Vignoles's works.

**Glasgow Technical College Scientific Society.**—"Kathode Rays and Allied Phenomena" by Prof. Blyth.

MONDAY, FEB. 6.

**Society of Engineers.**—At 7.30 p.m., presidential address.

TUESDAY, FEB. 7.

**Institution of Civil Engineers.**—At 8 p.m., further discussion on Mr. L. E. Clark's paper, "Floating Docks"; and, time permitting, the following papers will be read: "Alfreton Second Tunnel," by Mr. E. F. C. Trench; and "The Reconstruction of Moncreiffe Tunnel," by Mr. D. McLellan.

WEDNESDAY, FEB. 8.

**Tramways and Light Railways Association.**—At 3 p.m., visit to the works of the London United Tramways Company.

**The Dynamicables.**—Dinner at the Trocadero, preceded by a council meeting.

**Association of Engineers-in-Charge.**—At 8 p.m., "Belt Driving," by Mr. J. Tullis.

THURSDAY, FEB. 9.

**Institution of Electrical Engineers.**—At 8 p.m., "Fuel Economy in Steam Power Plants," by Messrs. W. H. Booth and J. B. C. Kershaw (conclusion of discussion); "The Value of Overhead Mains for Electric Distribution in the United Kingdom," by Dr. G. L. Addenbrooke.

FRIDAY, FEB. 10.

**Olympia.**—Opening of motor exhibition.

**Physical Society.**—At 8 p.m., "Radiation Pressure," by Prof. J. H. Pointing.

**Institution of Civil Engineers (Students' Section).**—"The Reconstruction of the Santa Lucia River Bridge, Uruguay," by Mr. P. J. Risdon.

**Tramways and Light Railways Association.**—At 8 p.m., annual meeting.

SATURDAY, FEB. 11.

**Junior Institution of Engineers.**—At 7 p.m., coming-of-age dinner at the Hotel Cecil.

**Birmingham Electric Club.**—At 7.30 p.m., "Lightning Conductors," by Mr. W. H. Whitehouse.

---

**Institution of Electrical Engineers (Manchester Section).**—Messrs. S. L. Pearce and H. C. Gunton will read their paper on "Manchester Tramways Power Supply" on Feb. 21, instead of Feb. 14.

*Bound Volumes of* "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, July to December, 1904, now ready.*

## MOTOR 'BUSES—OR WHAT?

It is just possible that the era of motor vehicles is nearer than is usually supposed, for the London County Council has had suggested to it by the Shoreditch authority the idea of such vehicles running on the existing system of old rails instead of electrification for the northern districts. It is estimated that a saving of nine hundred thousand pounds would take place were such a scheme adopted. There is no question as to the value of tramways when the conditions are favourable, but they are a nuisance when the conditions are unfavourable. Still, before adopting a scheme of motor traction, a good many things ought to be considered, and a pause made rather than a hurried acceptance. The conditions of town life are not good for the nerves, and doctors tell us that nervous complaints are increasing both in number and in intensity. Noise is a condition too prevalent. To obviate it in some measure various kinds of pavements have been adopted, and solid rubber or pneumatic tyres applied to vehicles. Can it be said that any of the motor 'buses at present running in the streets decrease the nuisance of noise? Rather do not these and the heavy motor engines conduce to a pandemonium that, if increased very largely, would drive half the population into lunatic asylums and the rest into the wilds of Canada? We are a curious nation. On the one hand, we spend extra thousands to get rid of noisy granite, while on the other encouraging the use and construction of noisier vehicles than the old broad-wheeled wagons. The result is very much as you were. There is a great lack of scientific imagination among the rising generation and the agitating section of the community, or we should long ago had in constant use a "unit of noise." Of course, we do not know its definition, or how its measure would be propagated, or we should have read a paper before some institution claiming two-and-twenty members, and our name would have had a chance to be remembered for more than nine days. However, there is hope yet. What cannot the student do when shown the way? A unit of noise. An Act of Parliament to prohibit anyone personally or by his vehicle or machine from producing more than $x$ units of noise at distance $y$ from any other living being. Pray, therefore, Mr. Councillor, reflect as to this question of noise before adopting for use motor vehicles which are promised for the future, but which do not exist in the present. We are credibly informed—indeed, it has been publicly announced at shareholders' meetings—that motor 'buses are soon to be running in considerable numbers in our streets. They are practical, have been successfully tried in units, and must come—so say the advocates. We have occasionally in our walks abroad met one of these monsters, but never when a second was within sight. One is quite enough, and we strongly fancy that when fifty or a hundred are found running within the length of the Strand they will be treated as an enemy within our gates, and destroyed without compunction or even a tear, unless the noisiness of the multitude is different in degree to that of the unit and considerably less. That practically noiseless motor carriages can be produced is certain. They can be seen daily in any part of the city. It is of the larger and more cumbersome vehicles, however, that we are speaking. Another nuisance is the stink. Multiply some motorcars in a crowded busy street, and the street would be unendurable. Still again a sign of the practicalness of the English. They multiply their sanitary "don'ts" on the one hand, and introduce a stinking, semi-combusted exhaust into the nostrils of every follower within a hundred yards or so. Mr. C. B. Fry

Digitized by Google

says 'tis healthy to breathe long breaths of fresh air. Let him try it on the Embankment some fine morning when there is a slight block and the exhausts of half a dozen slowly-moving motors just in front. There are incidents in life which conduce to vulgarity and the use of language. One of these is being in the redolent track of a badly-designed motorcar. But we must put up with all these little inconveniences because the question is progress, and it savours of frivolity to make silly complaints when it is known that "use is second nature," and men can sleep in the middle of an engineering factory, so familiarity will soon breed contempt of the noise of the rambackle traction engine and the box of mechanical tricks of the motor 'bus. The time of the motor 'bus will come, but the type as at present illustrating that useful vehicle will soon, if adopted, be a candidate for the scrap heap, and this is our moral. Electrical engineers and municipal authorities have been nauseated with recommendations to scrap, scrap, scrap, and renew with more modern machinery. What is the probability of the London County Council having to scrap its motorcars if the samples at present on show are really samples of the bulk? The motorcar, with its flexibility and half a score other advantages, is not quite proved. If it were, we could not suggest pause before accepting the proposal. What might with a certain degree of force be suggested is that the London County Council go gently with their tram schemes in all parts not favourable, and be satisfied for a while in developing those lines already constructed, and restrict further constructional work to any change over from horse to electricity, leaving new constructional work till after a little more experience is gained in motor-'bus work. It ought to be emphasised that the Shoreditch suggestion is not of a flexible system; its cars would be fixed to the tramlines, and the greatest advantage of motor traffic—capability of passing—would be lost.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### TELEPHONE RATES.

SIR,—Rejoinder to the reply to a reply:

1. If this definition of an editor's job is correct, no wonder that some editors perennially *are* in queer street.
2. The consideration of differing conditions in comparisons of telephone rates is the whole point. It is a consideration that is usually ignored.
3. The whole of the paragraph, of which you quote only a mutilated sentence, shows clearly that my statement that £5. 10s. was the pivot of the argument was correct, and that your statement that £5. 10s. was a figure "merely assumed for argument's sake" was incorrect. The argument was that a rate of between £5 and £6 was the standard to go by. £5. 10s. is exactly in the middle between £5 and £6.
4. Absence of comment does not necessarily imply agreement; it may imply mere weariness of spirit.
5. If you take out the fixed amount, £5 10s., or some other figure between £5 and £6, you destroy Mr. Bennett's whole argument. If you agree that it is a debatable matter whether a flat rate or some other form of payment should form the basis of calculation, you attack all Mr. Bennett's arguments, past and present.

As for my final remark, it was obviously based on your final remark of the previous week, in which you gracefully announced that telephonic up-to-dateness might be discussed till all was blue for aught you cared.

You are good enough to say that I think to little purpose. Doubtless if I had always been able to think with the amount of purpose that vitalises the air of Salisbury-court, and to express my thoughts with the clearness and force (not to mention the grammar) which distinguish the editorial columns of the *Electrical Engineer*, I should long ago have been rich and beyond need of thinking—except how to amuse myself.

You claim to have devoted more attention to telephonic matters than all the other English technical papers combined. All the other English technical papers combined might be inclined to contest that statement. But what *kind* of attention to matters telephonic have you paid, Mr. Editor? I have read some of the articles on telephony published in the *Electrical Engineer*, and I have some thoughts on them. Those thoughts may be purposeless, but I desire to express them. There was a series of articles on "Independent Telephony in Great Britain." It would be unkind to comment seriously on these, as they were too obviously the product of youth and inexperience. Besides, I am always glad to see telephone men sufficiently interested in their work to want to write about it. But the elementary nature of the information was more suitable to the columns of the *English Mechanic* or the *Amateur Electrician* than to those of a serious technical journal.

Other articles have appeared in your columns describing in all seriousness the systems recently installed for some of the British municipalities. These descriptions are interesting, because one is glad to have a record of the kind of technical work done in the municipal telephone systems. But frankly, Mr. Editor, to telephone men who know their business, and know the state of the art of telephony, the class of telephone work described in these articles is what whist players would call "bumble-puppy."

The writer of these articles (can he be my talented friend "W. O. T."?), in a description of a particularly foolish switchboard installed at Brighton, published in your columns last year, displayed his ignorance of modern telephone practice by a single remark. He spoke scornfully of the *many* disadvantages (the italics were his) of relays in telephone work. Now, sir, relays have been used in telephone work for many years. At the time your contributor published his sapient remark relays were in use on telephone circuits literally by the million. In cities in all parts of the world, from Japan to Portugal, from Scandinavia to California, relays do their daily work swiftly and accurately on millions of telephone calls. Are the great majority of telephone men ignorant of their business that they use many relays, with their *many* disadvantages, or did your contributor simply make a foolish statement based on ignorance and prejudice?

It seems to me that the amount of attention devoted by a journal to a given subject is of less importance than the quality thereof.

Let us turn to lighter subjects. I am glad to have amused Mr. Bennett. He must have perplexities enough. His other remarks suggest a parallel drawn from the past. Just about a hundred years ago the nursemaids of England, especially along the South Coast, used to frighten their small charges by threatening that "Boney" would come over and eat them up. Similarly, when anyone interested in the existing municipal telephone system hears any criticism of the theory and practice which governs those systems, he turns pale, and, in a frenzy of horror, says, "Oh! My God! National!"

Why, when municipal telephone work is stated by its supporters to be everything that is up to date and flourishing, the very name of the National Telephone Company should be such an awe-inspiring bogey passes my understanding. But so it is.

Mr. Bennett credits me with a range of operations that even the activity arising from the possession of a sound digestion and a fairly long pair of legs is hardly equal to. But, at any rate, he will agree that such advice as I have given the National Telephone Company has had quite successful results. Whereas, according to Mr. Bennett's figures, the municipal systems in competition gained only 4,687 stations in 1904, the National systems in the same places gained 8,074 exchange stations. In Glasgow, where the competition has waged the longest, the National gain was 5,232 exchange stations, as against 1,504 stations of all classes gained by the municipal system. At Glasgow,

Digitized by Google

therefore, the National rate of gain is 3½ times that of the municipal system, which shows pretty clearly how things are going, and indicates one reason why the Glasgow Corporation are obliged to consider rebuilding their telephone system.

I am frank to say that I should derive more pleasure from Mr. Bennett's communications to the Press if they were generally more logical and composed with greater respect for such details as grammar and spelling. The variety of work his lively imagination assigns me is obviously incompatible with an eight-hour day. Besides, when I "vilify," I never do it with more than one "l." (Happy thought: What length of praise is one ell of vilification equal to?) Mr. Bennett is very fond of criticising the work and ideas of others. Why should he be so susceptible and fly so readily to the use of hard words when his own work and ideas are criticised.—Yours, etc.,

HERBERT LAWS WEBB

[Mr. Webb is impulsive, and has to learn that abuse is not argument, but is regarded in legal circles as the refuge of the destitute. There are only two points in this very long letter that we care to touch. For the edification of Mr. Webb, the writers are not the same. Once more this £5. 10s. and argument. In our last issue we called attention to Mr. Bennett's article of Jan. 6, which was being criticised (save the word) by Mr. Webb in our issues of Jan. 20 and 27. We said that £5. 10s. was assumed for the sake of argument by Mr. Bennett, and that the argument would not suffer had the figures been £6. 10s. or £60. 10s. What Mr. Bennett's argument was, and, we presume, still is, is one easily put into abstract shape. Thus, American, Continental, British municipal, and certain of the National Telephone Company's concerns pay with a rate from $a$ to $b$ pounds per year; hence the Government in purchasing should not purchase at a price that when the system is made up to date should necessitate a rate more than $\frac{a+b}{2}$ pounds. If American, etc., practice had proved any other rate than $a$ to $b$ remunerative—say $x$ to $y$ pounds—then the factor before the Government would have been $\frac{x+y}{2}$ instead of $\frac{a+b}{2}$. The guide to Mr. Bennett was ascertained figures—the exact value of the figures not being necessary for the validity of the argument. The ascertained figures gave him £5. 10s.; it was not £5. 10s. that gave him the American, Continental, etc, figures. Mr. Webb is quite welcome to think the elimination of any special figure destroys an argument; it only shows that he needs very much to ponder Herbert Spencer's remarks: "We too often forget that not only is there a soul of goodness in all things evil, but very generally also a soul of truth in things erroneous. While many admit the abstract probability that a falsity has usually a nucleus of reality, few bear this abstract probability in mind when passing judgment on the opinions of others."

We have come to the conclusion that Mr. Webb's communications are not criticism—they certainly are not edifying, and unless he can restrict himself to the discussion of specific points of practice or organisation, leaving aside the absurd remarks which try to fashion a simple printer's error into personal inability to spell or write correctly, our columns are closed to him. We would suggest, if he is really in earnest, to give information and not vituperation, that he should amplify his views *re* flat rate or otherwise as a basis of calculation. If his otherwise does not involve a flat rate, direct or indirect, we shall be surprised—and edified.—ED. *E. E.*]

---

SIR,—I observe in your issue of the 20th inst. a letter by Mr. H L. Webb on telephone rates, in which he refers to the contemplated rearrangement of operating service in Glasgow. Permit me to state that Mr. Webb's remarks as to the necessity of rebuilding plant are entirely incorrect, as no rebuilding of plant will be necessary. His further remarks regarding the probable cost and the so-called telephone muddle, which appear to be the outcome of a prejudiced imagination, are too ridiculous for comment.—Yours, etc.,

JOHN MACFEE.

Glasgow, Jan. 25, 1905.

## ALUMINIUM.

SIR,—May I point out a slight error which I notice in Mr W. Smith's paper on aluminium, printed in your issue of Jan. 27.

Comparing the relative advantages of aluminium and copper conductors, Mr. Smith shows that the diameter of an aluminium conductor must be 1·3 times the diameter of a copper conductor of equal conductivity. In order to have the same leakage current in both cases, the thickness of the insulation must be proportional to the leakage area. Now, this leakage area is proportional to the diameter of the conductor, not to its area, so that we ought to have

$$\frac{\text{Insulation on Cu.}}{\text{Insulation on Al.}} \propto \frac{1}{1{\cdot}3}, \text{ instead of } \frac{1}{1{\cdot}69}.$$

—Yours, etc.,

R. T.

Jan. 25, 1905.

---

## THE METRIC FALLACY.

SIR,—Will you allow me to correct a few errors into which a recent letter of Mr. E. Johnson, secretary of the Decimal Association, indicates he has fallen regarding American weights and measures? He says: "Within the last few years the United States have adopted a ton of 2,000lb, and have adopted a yard derived from the metre."

I did not expect, in exposing the metric fallacy, to have occasion to defend the 2,000lb. ton against the charge of extreme youth. The following extract from the report on the metric system by John Quincy Adams, sent to Congress in 1821, shows not only that this ton was an established standard then, but also calls attention to some useful relations between our standards, which those who are accustomed to vilify the British system might study with profit: "There are, nevertheless, very useful proportions in our existing weights and measures, one of which is the ton measure of water and the pound avoirdupois. As 1,000oz. avoirdupois weigh exactly one cubic foot of water, it follows that the ton of 2,000lb. weight is the ton of 32 cubic feet measure. The other is between the pound avoirdupois and the pound troy; the former consisting of precisely 7,000 grains troy. The pound avoirdupois is, therefore, the connecting link between weight and linear measure."

The 2,000lb. ton is the popular standard for heavy weights in the United States. The 2,240lb. ton is used for mining, wholesale trade in coal, and some other purposes; it is called the gross ton to distinguish it from the other, and its use is decreasing as compared with the more convenient 2,000lb. ton.

In a former letter I referred to the pretence that our yard is derived from the metre, and will add here that the supposed verification of our yard bar at Washington by comparison with the lines on the metre bar is merely an approximation, because the yard is incommensurable with the decimal divisions of the metre, the ratio between the two, as determined by Kater, being 1·093633056. This claim of a yard derived from the metre is thus a fallacy based on a myth.

Mr. Johnson is also in error regarding the size of our gallon, which is the same as the old English wine gallon. It is one-sixth smaller than the British gallon, not one-fifth as he states. It is fortunate, however, not only that the difference between the two gallons is expressed by such a simple ratio, but that this, the only discrepancy in Anglo-American conformity, is found in liquid measures, where it causes less trouble in international transactions than in any other class of standards. The difference between the two gallons will not be without compensation if it serves as an awful warning against allowing further variations to arise.

Mr. Johnson's belief that it is only the names of the old standards that survive in some parts of France is not confirmed by French manufacturers. Thus Lamoitier, in *l'Industrie Textile*, Paris, October, 1902: "We are as much in the anarchy of weights and measures for the textile industry as at the time of the Revolution. . . . After having established the metric system, is it not truly ridiculous that more than 110 years later we should be still using the English yard, the old or French pound, the denier of Montpellier or of Milan, the ancient aune, the many different skeins, etc?" Greece is another example of

Digitized by Google

the "majority of nations" that, according to Mr. Johnson, have "adopted the metric system" Greece adopted the metric system in 1834, being the first to take such action after France. Last year, or just 70 years later, a semi-official chart of Greek weights and measures was published. From beginning to end it is confusion worse confounded of old and metric measures.

Mr. Johnson asks if the survival of "customary" British standards is to be accepted as an argument against the British system of weights and measures Not an argument against the British system, but it is an unanswerable argument against any attempt to introduce the metric system If the "customary or illegal" units have survived, how can it be possible to sweep away the entire British system and supplant it with the metric? The metric proposition hinges on that question, and no satisfactory answer to it has been made on either side of the Atlantic. The introduction of the metric system means chaos for English-speaking countries, because the English system in use as a single standard by a rapidly expanding population of 140,000,000, inhabiting or controlling 14,000,000 square miles of territory, cannot be abolished. Such a proposition is an absurdity.

The greatest error Mr. Johnson makes is in thinking that "America is no longer with you." America is with you in language, common law, weights and measures. They are her birthright, which she is not likely to sell for a mess of metric pottage.—Yours, etc., SAMUEL S. DALE.

Boston, Mass., Jan. 20, 1905.

## THE LAY OF THE SPIDER.

### A Pathetic Ballad.

BY SIMPLEX.

NOTE.—*The Next Thing in Advertisements*—Shift engineer wanted for large generating station. Good mechanical training and previous experience in high and low tension electrical work essential. Salary, 10s. per week. Promotion according to ability. Free air and scenery provided. Write early and avoid the crush.

The Engineer (Junior) flung himself down
In a lonely mood, to think.
He'd searched all his pockets and hadn't a brown,
Or else he'd have taken to drink.

He'd wrestled with switches and battled with Fate;
He'd shifted a shift by himself;
He'd tended the voltmeter early and late;
He'd a pitiful absence of pelf.

He'd written for jobs by the dozen or score;
He'd petitioned the Chief for a rise—
The meek applications were heard of no more,
And the Chief had (beg pardon)-ed his eyes!

When lo! A big spider came down on a thread
And crawled from the 'bus bars to earth;
And that horrified spider curled up and was dead
(Which isn't a subject for mirth).

The Engineer (Junior) sprang up with a cry.
"That spider," quoth he, "shows the way!
There's a glut in the market! 'Tis for me but to die.
Let anyone else have my pay!"

He wrote to the Chief, with a tear in his eye,
A letter which caused Him surprise.
And then he sat down on the H.T. Supply—
Immediately getting a rise!

## FUEL ECONOMY IN STEAM POWER PLANTS.

A paper on this subject was read before the Institution of Electrical Engineers by Mr. W. H. Booth on the 12th ult., and elaborated by his co-author, Mr. J. B C. Kershaw, with experiments, on the 26th ult. The paper was divided under seven headings, any one of which was sufficient for a full paper if exhaustively treated. The seven headings were: feed water, fuel, air, boilers and furnaces, steam, waste gases, and draught and regulation of air supplies. It is under the third heading—boilers and furnaces—that the most valuable information is given, but here, again, the authors were evidently handicapped by the limited space at their disposal. Their remarks as to the design of furnaces for burning particular kinds of fuel with the three principal types of boilers will repay careful reading, and we regret that we cannot reproduce in full this section of the paper.

The paper concludes thus: "Finally, may the authors point out that the best results can only be attained if scientific methods of control are employed in relation to feed water, fuel, waste gases, and draught. Automatic apparatus for testing flue gases or any other product can never take the place of the trained chemist; for an automatic apparatus demands not less but more skill in its control and management than ordinary apparatus, if the records obtained by it are to be of permanent value. The results now being obtained by $CO_2$ recorders in many electricity works are, in the authors' opinion, of doubtful value, owing to the lack of trained expert assistance in their management. Automatic apparatus of all kinds is, we admit, of great service, but not in the direction popularly supposed. It enables one skilled and efficient man greatly to increase the number and extent of his duties, and practically to treble or quadruple his efficiency; but it does not, and cannot, give accurate and valuable records when placed in the hands of untrained men. It is remarkable that engineers, after their long experience of automatic stoking appliances, should imagine that automatic testing apparatus will achieve the impossible. In each case the best results can only be attained when the automatic apparatus is under expert supervision and control; and for testing apparatus, the expert control required is that of a specially trained and skilled chemist. In the working of a large modern boiler plant the chemist is, in fact, as much in place as in a chemical works, and the recognition of this truth will undoubtedly promote the economical working of such plants.

"The following words, written over 60 years ago by the pioneer in the movement to obtain more scientific use of coal and fuel in steam-raising—we refer to that remarkable man, C. Wye Williams—are still applicable to the position in this year, 1905, and there are few present who would guess that they were a quotation from a book entitled 'The Combustion of Coal,' published in the year 1841 in Liverpool, and dedicated to the proprietors of the City of Dublin Steam Packet Company: 'It may be asked how it has happened that hitherto the smokeless combustion of fuel has not been effected. I answer, because the *chemistry* of combustion has been neglected, not in the laboratory, but *in practice*, and because the construction of our furnaces has been too much left to those who know little of the chemical properties of the materials which are consumed in them.'"

The following is a summary of the discussion:

**Colonel Crompton** prefaced his remarks by stating that electrical engineers scarcely appreciated how much their interests were bound up in the subject of the paper, which was a most opportune one. He entirely agreed with the authors in regard to flame temperature and the cooling effect of the boiler surfaces. The method introduced in this country when water-tube boilers were first used of putting the furnaces very close to the cooling surface of the tubes was a barbarous one. The technical Press had urged that you could not prevent or consume smoke without loss. So long as there was an excess of air that view was to a certain extent correct, but the authors' method of deflecting the gases on a firebrick lining was the remedy for preventing smoke. Instead of causing loss, this method, properly worked, would give a higher economy. At Calcutta he had introduced water-tube boilers against the advice of all the practical engineers there, but the Calcutta electricity supply undertaking was virtually the only smokeless establishment in the district. He considered that thermal storage had not only come to stay, but would prove to be one of the greatest benefits ever introduced into power stations, particularly where there was a peak load. Not only did it signify economy in boiler plant, but there was an economy of a kind which could not be explained at the present time, as the energy became multiplied by some unknown means. On this point he did not agree with the authors that you must wait to ascertain the cause before utilising thermal storage; the effect was known, and that was sufficient. Mr. Booth still had an affection for the Lancashire boiler, but Colonel Crompton was glad to see that he now received water-tube boilers with toleration. With the latter you could arrange to have a superheated coil put in the right place, and you could have the superheater surfaces brought as near as possible to the hottest part of the fuel, which was almost impossible with the Lancashire boiler. Regarding furnaces, this was a question of fuel. When fuels with varying percentages of ash were

Digitized by Google

used, a moving furnace was an enormous advantage, because it could be run at varying speeds to suit the varying percentages of ash. In regard to the inclined grate, the party which recently toured the States had several opportunities of seeing the Rooney type, but after extensive enquiries Colonel Crompton had come to the conclusion that the results were not comparable with those obtained with the flat grate worked on the chain or similar principle. Colonel Crompton spoke enthusiastically of superheated steam. When in America he discussed this very fully with Dr. Elihu Thomson, who considered that the steam-engine would be kept on a level with the internal-combustion engine, and in some respects surpass it, "if we have the pluck to go high enough in temperature." He hoped engineers would not accept the authors' view that the only advantage of superheating was to dry the steam. Superheating gave thermodynamic advantages the whole way up the scale. By its means Dr. Thomson and others had obtained results only to be accounted for by the third law. Superheating had been unjustly criticised because it was supposed to score the cylinders and to evaporate the lubrication. Colonel Crompton had satisfied himself by experiments that this did not occur when the boilers were properly worked. The gain amounted to between 30 and 40 per cent., not 15 per cent. as stated by the authors. He was sorry that in an otherwise excellent paper the authors did not give credit under this head to Profs. Callendar and Nicholson, who read a paper on the subject in 1898. Colonel Crompton was convinced that a new practice in steam engineering could be developed with quite as bright a prospect of profitable results as from internal-combustion engines.

**Mr. H. P. Boot** (Tunbridge Wells) said that his experience in regard to the separation of oil and grease from condensed water was that there was no trouble at all, provided the grease was put in the proper place and arranged at the right level. In regard to feed-water heating, he had for some time been trying a method of passing the water from a hot-well, after it leaves the economiser, into an arrangement of trays in the heat space of the boiler. This answered its purpose well, but it was necessary to provide for the contraction and expansion of the trays. He had been surprised to hear Colonel Crompton speak somewhat disparagingly of the Lancashire boiler. He considered the central-station engineer's lot was a happy one where a combination was in vogue, the Lancashire boilers being of great value in the daytime. The water-tube boilers were certainly very valuable for rapid steam-raising. As to refractory furnaces, it was a subject of surprise to him that makers of water-tube boilers should still go on constructing the old-fashioned type of chamber. As to the most economical class of fuel, it depended entirely on the location of the town, railway carriage being the determining factor. He had never been able to exceed 18 per cent. in the saving by superheated steam, but that figure was a good reason for adopting superheat.

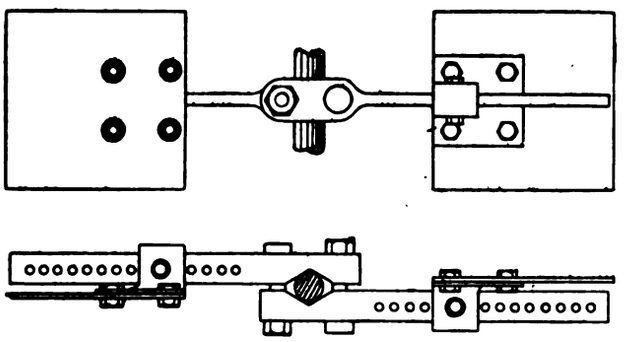
**Mr. Dale** (of Messrs. Crossfield, Warrington) said that his experience confirmed the authors' view as to the possibility of obtaining better fuel economy. As to the frequency of the analysis of the water, this depended upon local conditions. He agreed with the authors' view generally, but as the hardness of the water his company obtained from the Mersey fluctuated a good deal and was sometimes abnormal, it necessitated a certain amount of extra analysis. Great care should be taken to exclude animal oils from the feed water. In regard to firing, hand stoking introduced an element of irregularity, whereas with a first-rate mechanical type practical uniformity was obtainable. Respecting sampling and analysis of fuel, he agreed that as a general rule an approximate analysis was quite sufficient, and the calorific value could be calculated from this. In some cases it might be desirable to conduct an ordinary calorimeter test. With regard to superheating, Mr. Dale described a method employed at his company's works. Most of their Lancashire boilers were 30ft. by 9ft., and instead of covering the top with non-conducting material, they utilised it as heating surface, and over this were fixed two horizontal tubes. A gain of 7deg. to 8deg. of superheat was obtained, which, though not great, was uniform.

**Mr. Druitt Halpin** quite agreed with the authors' views about batteries. If a good battery were obtainable at moderate cost, it would be a boon. In regard to the boilers, he emphasised the need of getting rid of the dirt before the feed water could carry it into the interior. Regarding lubrication, animal oils had practically ceased to be used. In regard to fuels, he thought it as well to use the best where the prices were anything like proportionate, but did not believe in burning the best Welsh when the price was abnormal. Fans were the best method of improving chimney draught. He agreed with the authors that it was folly to have cheap engines to tide over the peak load. He favoured the water-tube boiler for all-round efficiency.

## TRADE NOTICES AND NOVELTIES.

### Absorption Dynamometer.

The dynamometer illustrated herewith has been designed by Mr. W. G. Walker, A.M.I.C.E., M.I.E.E., of 47, Victoria-street, S.W., for measuring the horse-power of electric and other motors. It will be seen from the illustration that it is of the absorption type, the energy produced in the motor being expended by the vanes revolving in air. Mr. Walker has designed such a dynamometer with a range of from $\frac{1}{4}$ h.p. to 20 h.p. For this range three different sizes of air-vanes are provided. The radial arms can be clamped on to shafts varying from $\frac{3}{4}$in. to $1\frac{3}{8}$in. in diameter. The weight complete of the whole apparatus, including the box, is about 22lb., and the over-all dimensions of the box is 24in. by 9½in. by 6in. The method of using the dynamometer to ascertain the horse-power of an electric or a petrol motor is as follows: The radial arms are clamped on to the spindle of the motor to be tested, and the vanes adjusted to such a radial position that the motor runs at the required speed under load. Knowing the speed and the position and size of the vanes, the horse-power is obtained from tables of results which are supplied with the dynamometer. There is no doubt that such an apparatus can be easily



Walker's Absorption Dynamometer.

fixed to a motor for testing purposes, but we are inclined to think that the reading of horse-power obtained will be considerably varied by the position of the motor relative to the floor, walls, or other surrounding objects. We presume the designer has looked into this and may be able to give some corrections to be applied in extreme cases.

### E.C.C. Machines of Recent Design and Construction.

Through the courtesy of the Electric Construction Company, Limited, Wolverhampton, we are able to illustrate herewith

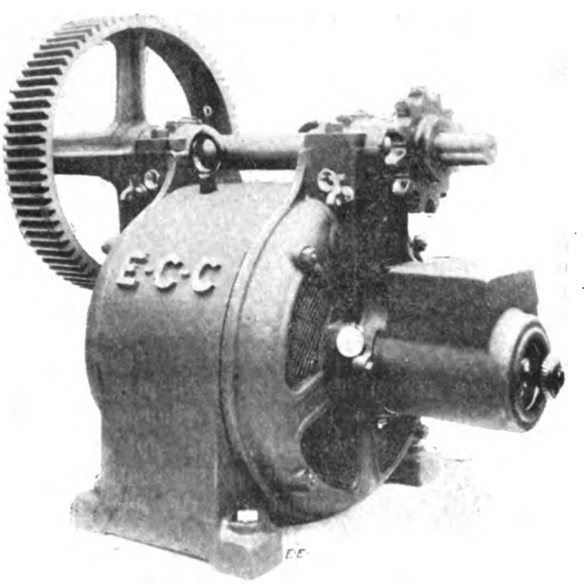


FIG. 1.—E.C.C. Standard Slip Ring Induction Motor.

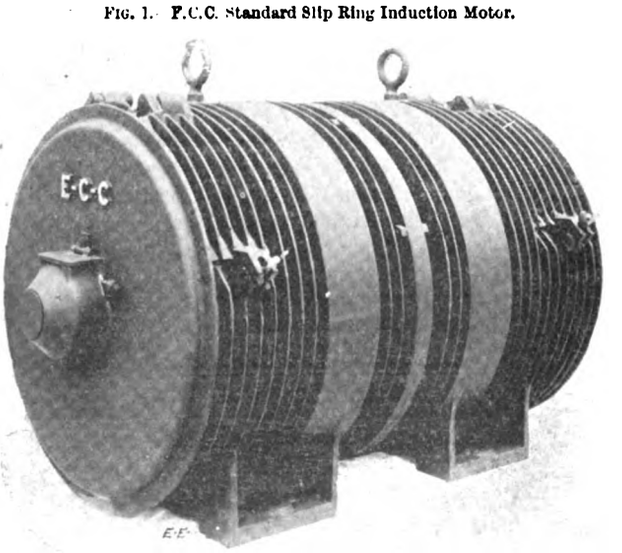

FIG. 2.—E.C.C. Enclosed Motor-Generator.

some of the machines recently manufactured by them. Fig. 1 shows one of the firm's standard induction motors, with brushes

Digitized by Google

and slip-rings enclosed in a cast-iron ventilated cover. The brushes are of carbon, and the motor is provided with a short-circuiting and brush-lifting arrangement. The particular machine illustrated has an output of 15 b.h.p. when running at 720 revolutions per minute. It is wound for two-phase currents at a potential of 200 volts, and is geared by means of a raw-hide pinion and cast-iron spur wheel down to 240 revolutions per minute, the drive being then transmitted with further reduction to the countershaft through the medium of chain gear. Referring to the illustration, it will be seen that the starting resistance and switch are carried at the end of the shaft and completely enclosed. This arrangement saves the ohmic loss in leads which would be entailed by a separate starter, while it effects at the same time a saving in the initial cost, and renders the whole more efficient. The bearings for the countershaft are cast on the end casings. This construction, apart from the great stiffness obtained, is much preferable to the practice of bolting the bearings for the countershaft on to the motor case, since it ensures accurate pitch. It will also be noticed that the construction employed enables the end covers to be moved round bodily, with their respective attachments, to different points, so as to adapt the motor for any position. Thus it may be belted either to the floor, wall, or ceiling, as may be required, without difficulty. The countershaft bearings have very little overhang. Fig. 2 represents one of a number of motor-generators for a Government contract. This machine has an output of 50 amperes at 15 volts when running at 1,200 revolutions per minute. The motor and generator are direct coupled, the whole being completely enclosed in a cast-iron case ribbed externally, as shown, in order to obtain a greater heat-radiating surface. Sections of the casing are hinged to permit of ready access to the brushes. Fig. 3 illustrates a 220-kilo-volt-ampere motor-generator running at 428 revolutions per minute.

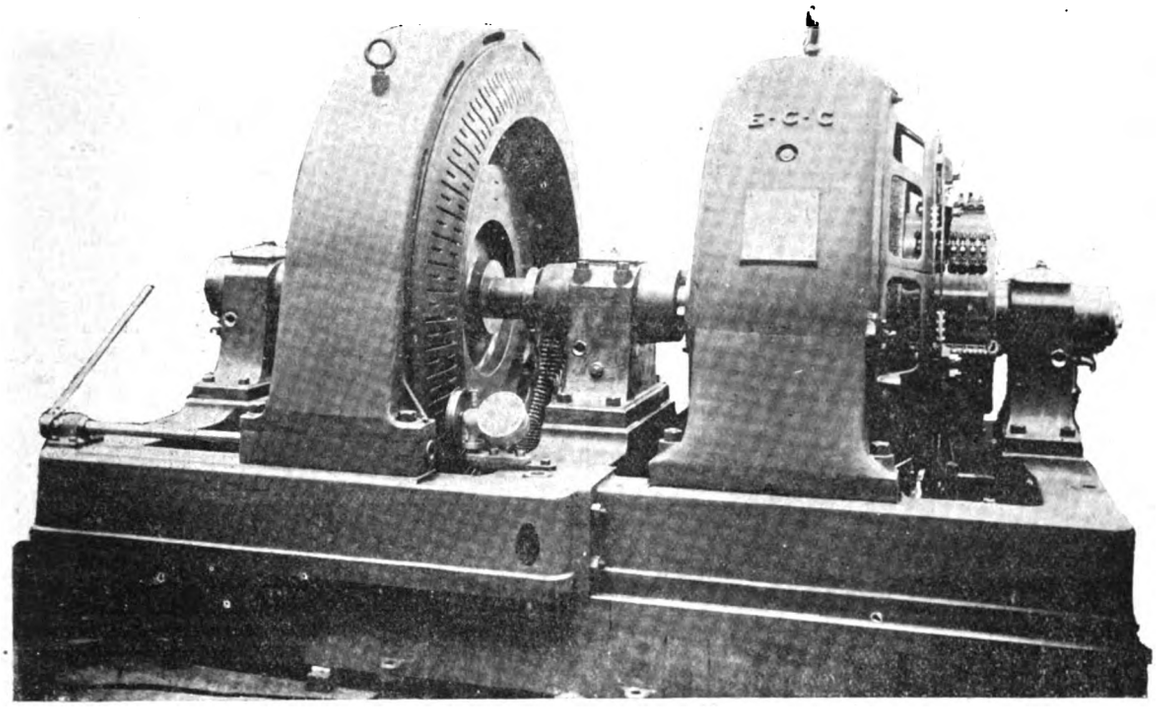

FIG. 3.—E.C.C. Motor-Generator.

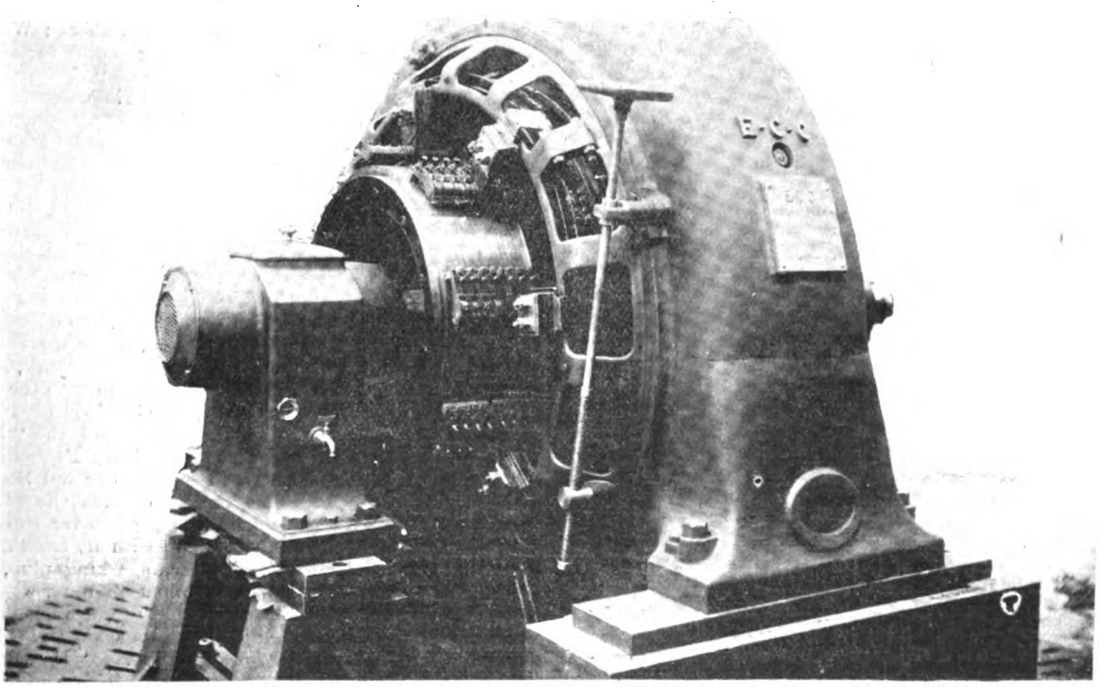

FIG. 4.—E.C.C. Traction Generator.

The motor half of this combination is shunt wound for 440 to 450 volts, and is supplied with current from tramway generators. It is direct coupled to a three-phase machine wound to generate current at 3,000 volts terminal potential. Thus the combination is the reverse of the usual order of things. The last of the accompanying illustrations (Fig. 4) shows a 375-kw. compound-wound traction generator of the firm's latest type of

Digitized by Google

construction, designed for a speed of 350 revolutions per minute and a terminal potential of 500 volts. No better proof of the E.C.C.'s successful efforts to maintain a leading position in regard to the design and manufacture of modern electrical plant could be afforded than these illustrations, and we must compliment the firm upon their steady progress with the times.

### Steam.

Messrs. Babcock and Wilcox, Limited, of Oriel House, Farringdon-street, E.C., have sent us a copy of the fifth edition of their book entitled "Steam." In the new edition of this well-known work of reference no less than 180 pages are required to contain the information given. This book, which was first issued in the United States, gives concisely the history of the Babcock and Wilcox boiler since its inception in 1867. The development of these boilers, which now have reached the aggregate output of 4,700,000 h.p., has coincided with a great advance in the economical production of steam. It follows also that the company responsible for the manufacture of such a large number of boilers must be intimately in touch with every feature in connection with steam production. The book before us is evidence of this, and, quite apart from the descriptions given of Babcock and Wilcox apparatus, it contains data which is unprocurable elsewhere, and is invaluable to engineers. With the early part of the present edition we do not propose to deal, but must call our readers' attention to the valuable tables that are given from p. 63 onwards as to the theoretical heating values of the coals of the world. In this section information is given as to the calorific values of coals obtainable in Great Britain, the United States, Germany, France, and most other Continental countries. These figures are followed by useful information as to the Australian coals and the products of the coal mines in South Africa, Japan, etc. In places where fuel other than coal is found more economical, special furnaces are needed, and here, again, the information given in "Steam" will be invaluable to engineers having an export practice. The superheating of steam is now adopted in all new electricity works, and a number of our older stations have found it advisable to add independently-fired superheaters. This branch of steam engineering is much more fully dealt with in the present edition than in the earlier issues of this publication. Both the superheater worked as a part of each boiler and the independently-fired superheater are discussed. There has been in the past considerable trouble with the latter type, owing to the fact that there is no automatic relation between the heat produced by the furnace and the quantity of steam which is passed through the superheater tubes. If, however, the essential conditions which are laid down for the design of such superheaters are followed, the burning-out of tubes and other troubles will be avoided. It is essential that the tubes should not be subjected to the direct impact of the furnace gases rising from the firebars. They should instead be placed in a chamber completely filled with burnt gases of as low a temperature as practical to ensure the final superheat required. This involves a large heating surface, which is more than repaid by the increase of life of the superheater and the decrease in trouble and cost of repairs. The other details, such as ensure freedom of expansion for the tubes and tight joints between the tubes and the manifolds into which they are secured, should receive the attention of engineers when deciding between the relative merits of different superheaters. Elsewhere in the volume a considerable amount of new information is given on refuse destructors. The feature, however, of the issue from an electrical engineer's point of view are the illustrated descriptions of large boiler plants in power stations designed for the electrical distribution of power on a scale which was undreamed of when the first edition of "Steam" appeared. In connection with these the automatic coal-conveying installations are worthy of special notice, and automatic stoking is also dealt with. This last edition has also been improved by the inclusion of the results of some recent trials and by a number of additional tables of general interest. The book should find a place amongst every engineer's works of reference.

### Catalogues.

THE SIMPLEX STEEL CONDUIT COMPANY, LIMITED, Birmingham, London, E.C., and Manchester.—Leaflet No. 102 shows important percentage reductions in the price of material which were effected on the issue of their last list. The leaflet deals with light-gauge, heavy-gauge, and oval conduits, fittings, junction boxes, and miscellaneous. The reductions vary from 12·4 to 25·7 per cent., while the average reduction in screwed normal bends amounts to 57·6 per cent.

## AUTOMOBILE SHOW.

A small automobile show is being held at the Crystal Palace, and will remain open until Feb. 4. Perhaps its most interesting feature consists in trials of non-slipping devices, which are being held on a specially-prepared surface in the grounds. We learn that in order to ensure that all the appliances being tested are practical, they will be required to undergo a test of a 50-mile run on the roads. Some of the stands have made extensive use of 2-c.p. and 3-c.p. incandescent electric lamps, arranged in festoons, for effective and decorative lighting. The various tyre and accessory firms have been allotted prominent positions, and have not, as in former years, been hidden away in galleries or other out-of-the-way positions.

Electric carriages are, as usual, very much in the minority. The Kriéger Electric Carriage Syndicate, Limited, 48A, Gillingham-street, Eccleston-square, London, S.W., exhibit front-wheel-driven electric landaulets, coupes, landaus, victorias, 'buses, and delivery vans, all system Kriéger, with two compound 4½-h.p. motors. The following particulars are given: Speeds—six forward, two recuperation, one full brake, and one reverse; transmission—direct by means of pinions keyed to driving wheels; controller—situated below steering handle, and is easily manipulated; brakes—one electric and one mechanical; steering—is very simple, and can be fitted with either wheel or handle bar; chassis—steel stamped; tyres—either pneumatic or solid; accumulator—44-cell battery, which has a capacity of 45 miles on one charge for a four-seated car. The Scheele Electric Carriage Company, 41, Grosvenor-mews, New Bond-street, W., show an electric Victoria brougham having interchangeable bodies, with one chassis, a battery capacity 40 to 50 miles, five speeds forward and two backwards; the speed is given at 14 to 20 miles an hour. They also show an elegant electric private omnibus. Messrs. Glaskin and Co., Grosvenor-mansion, Victoria-street, Westminster, London, S.W., have on view their electric-Stanhope. Messrs. B. Kuettner and MacDonell, 3, Adam-street, Adelphi, London, W.C., have a splendid display of casting machines and moulds, and various types of grids, frames, and plates for accumulator makers for ignition, traction, or stationary work in England; also an electromagnetic sorting machine for separating metal by electricity, and a variety of accumulator accessories. We also noticed a complete outfit for electrically lighting motorcars, electric head, side, and tail lamps, and roof light for covered cars, all run off from one small accumulator battery.

Messrs. David Moseley and Sons, Limited, Chapelfield Works, Ardwick, Manchester, and London, Glasgow, and Birmingham, exhibit their well-known varieties—viz.: Moseley's beaded-edge and new wired motor tyres, Seddon's red tubeless motor tyre, and all rubber accessories for the motor trade. Messrs. J. G. Statter and Co., Newhall-street, Birmingham, show a new electrically-driven valve-grinding appliance for the use of car owners and garages.

Messrs. W. H. Willcox and Co., Limited, motor engineers' stores and lubricating oil refiners, 23 36, Southwark-street, London, S.E., have a fine show of their specialities, including Willcox aluminium-cased "centrifugal" and semi-rotary motor pumps for circulating water in the cooling chambers; Willcox gun-metal "semi-rotary" water-circulating pump for the cooling chambers (in two sizes); several types of "Penberthy" patent injectors, etc. The Gratze Patents and Engineering Syndicate, Limited, 44A, Whitfield-street, Tottenham Court-road, W. show a new speed indicator, which is formed on an altogether new principle of action; the indicating movement is quite distinct, and absolutely disconnected from the rotary portion of the instrument. It has a positive gear drive, thus obviating any slip that would otherwise accompany a friction drive. They also exhibit a type of accumulators suitable for ignition purposes, traction, or lighting—an altogether new formation on the Planté principle, in which the positive plates are not pasted. It appears that the firm guarantee this accumulator to give an output of 18 watts per pound weight, and they claim that it will give one volt even under a dead short-circuit, and that it can be charged at 200 amperes without injury to the plates.

Messrs. G. T. Riches and Co., 4, Gray's-inn-road, London, W.C., are the sole British representatives of the "Eisemann" high-tension magneto-ignition, as used by Panhard, Lavassor (exclusive), Brooke, Daimler, Merryweather and Son, Limited, M. M. C. Wolseley. This machine takes the place of the accumulator and contact breaker, and whatever the number of cylinders used requires only one coil without trembler. High-tension system with ordinary pattern sparking plug, in connection with which they show a combination plug, with porcelain interior, doing away with the trouble of mica heads; Simplex electric ignition (combined coil and sparking plug), and wipe contacts for 6 h.p., 8 h.p., and 9 h.p. "De Dion" (G. T. Riches and Co.'s registered design, guaranteed interchangeable) are also found on this stand. Voltmeters, coils, sparking plugs, accumulators, and ignition sundries of various kinds are also exhibited by Messrs. Alfred Dunhill, Limited, 359 and 361, Euston-road, N.W.; Leadbitter and Co., York-street, Westminster; Peto and Radford, Limited, Hatton-garden, E.C.; Longstreth's, Limited, 427A, Strand, W.C.; Chloride Electrical Storage Company, Limited, 39, Victoria-street, S.W.; C. A. Vandervell and Co., Chapter-road, Willesden, N.W.; and the Magneto Company, Winchester House, E.C.

Digitized by Google

## INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting on Jan. 26 the following candidates were elected :

*Associate Members.*—H. H. Couzens, Corporation Electricity Works, Temple Back, Bristol ; A. Crowther, W. R. Asylum, Menston, near Leeds ; J. N. Dodd, Messrs. Dick, Kerr, and Co., Preston, Lancs. ; D. B. Ingram, Ishapur Rolling Mills, Calcutta ; B. A. Mannerheim, care of Swedish and Norwegian Consulate, Johanneeburg, Transvaal ; W. H. Moore, superintendent-engineer to the Port Commissioners, Calcutta ; A. S. Munro, Corporation Electricity Works, Pietermaritzburg, Natal ; A. Peaker, Ashley House, Lady Pit-lane, Leeds ; F. K. Preston, Bradford Dyers' Association, Limited, Bradford ; T. B. Reader, Electric Lighting Station, Hindhead, Surrey ; T. W. Sampson, 18, Bute-street, Crookes, Sheffield ; W. T. Taylor, Rawhide Gold Mining Company, Rawhide, California, U.S.A.

*Associates.*—L. H. A. Shadwell, Government Harbour Department, Durban, Natal ; T. Wadsworth, 51, Bradbourne-street, Fulham, S.W.

*Students.*—W. Aked, Highfield House, Sutton-in-Ashfield, Notts ; S. M. Andrews, 41, Wellington-road, Old Charlton, S.E. ; J. T. Appleton, 91, Bewsey-road, Warrington ; A. Auer, 35, Victoria-street, Aberdeen ; H. A. Bastable, 41, Wellington-road, Charlton, S.E. ; G. C. Blackburn, 9, Circular-road, Birkenhead ; F. G. Broadhead, 9, Meyrick-road, Stafford ; S. Brooks, 71, Haworth-road, Gorton, Manchester ; T. A. Brown, 90, Hadham-road, Bishop's Stortford, Herts ; W. Browning, Laurel Bank, Mornington-road, Sale, Manchester ; R. P. M. Canty, 24, Woburn-place, W.C. ; H. A. Carney, 59, Marshall-place, Cheetham, Manchester ; L. H. A. Carr, 15, Albert-terrace, North Shore, Blackpool ; A. E. Clarke, 132, Hulton-street, Moss Side, Manchester ; G. W. Cosby, 86, Shrewsbury-street, Old Trafford, Manchester ; P. G. Dani, 5, Girdler's road, Brook Green, W. ; R. E. Dawson, 42, High-street, Southend-on-Sea ; A. J. C. De Renzi, 54, King-street East, Rochdale ; C. H. Dobson, Elmside, Rusholme-road, East Putney ; G. A. Egles, 192, Marylebone-road, N.W. ; C. F. Embleton, 90, Oxford-road, Manchester ; J. G. Farrow, 229, Albion-road, Stoke Newington, N. ; R. A. F. Fawcus, Red House, Altrincham, Cheshire ; H. A. Finlaison, 11, The Park, Eccles, Manchester ; D. Fox, 2, Lindum-terrace, Bradford ; J. W. Fraser, 11, Haverhill-road, Balham, S.W. ; J. P. Garner, Post Office, Spurstow, Tarporley ; W. W. Greenwood, Elsmore Heath Villas, Halifax ; C. H. W. Grimshaw, Fairy Hill, Bray, co. Wicklow ; J. W. Hambleton, 30, Bloomfield-avenue, S.C. Road, Dublin ; C. C. A. Hardie, 7, Melina-place, St. John's Wood, N.W. ; A. W. E. Harris, The Red House, Barnt Green, near Birmingham ; T. Hedberg, 349, Collins-street, Melbourne ; H. Helweg-Larsen, 63, Northern-grove, West Didsbury, Manchester ; P. H. I. Humphreys, Lendal-hill, York ; P. Kemp, 144, Stockport-road, Manchester ; E. W. Lace, St. Leonard's, Ryde, Isle of Wight ; E. Lawson, Scatcherel-hill, Morley, Yorks ; J. H. Lemon, Engineering Apprentices' Club, Stretford, Manchester ; L. J. Lepine, 6, Queen's-road, Loughborough ; A. E. McConnell, Mortimer House, Victoria-road, Stretford, Manchester ; R. L. McCulloch, 56, Aytoun-road, Pollokshields, Glasgow ; J. S. Mail, 1, Bisham-gardens, Highgate, N. ; A. Maling and S. Y. Maling, 11, Derbyshire-lane, Stretford, Manchester ; C. E. May, Treasurer's House, The College, Bromley, Kent ; E. N. G. Morris, Brentford Lodge, Old Brentford, Middlesex ; J. H. Mousley, St. Germains, St. Albans, Herts ; J. H. M. Nichols, 30, Maitland Park-villas, Haverstock-hill, N.W. ; A. E. O'Dell, 9, Gordon-road, Kingston-on-Thames ; W. A. Perry, 59, Wallwood-road, Leytonstone ; K. Preston, 7, Groby-road, Altrincham, Cheshire ; E. S. M. Prichard, 37, Derbyshire-lane, Stretford, Manchester ; V. J. Radbone, 58, Lordship-park, Stoke Newington, N. ; H. S. Rainforth, Central Technical College, South Kensington, S.W. ; N. Ramsay, Cams Hall, Fareham, Hants ; A. Riley, The Poplars, Morley, near Leeds ; J. M. Seddon, 10, Queen's-square, W.C. ; S. Simpson, 119, Earl-street, Horton-lane, Bradford ; J. W. Smith, 16, Gladstone-street, Loughborough ; N. B. Tomlinson, 13, Pembury-avenue, Tottenham, N. ; E. W. Tunbridge, Rocklands, Woodbourne-road, Edgbaston, Birmingham ; W. Turner, Grosvenor Lawn, Newbury, Berks ; G. W. Wadsworth, 13, Glenfield-street, Cloughside, Blackley ; T. F. Wall, 21, Norwood-grove, Liverpool ; J. W. Wheeler, 250, Amhurst-road, N. ; S. M. Wright, 20, Muswell-rise, Muswell-hill, N. ; A. R. Wuest, 17, Amherst-street, Withington-street, Manchester.

## PERSONAL.

Mr. A. A. Blackburn, A.M.I.E.E., who had resigned his position under the Manchester City Council for one with the Belfast Corporation, was on Friday last presented by Mr. Councillor G. T. Jackson, J.P., general secretary of the Tramworkers' Union, and on behalf of that body with a handsomely illuminated and framed address and a gold-mounted umbrella. In doing so, Mr. Jackson said it was one of the greatest pleasures which fell to the lot of a general secretary, for it showed that a happy understanding had existed between the men and Mr. Blackburn, whom they all hoped would continue to rise in his profession, and that however high, or wherever he went, the same happy conditions would exist around him as had prevailed during his 2½ years at Manchester. Mr. Blackburn had been previously presented by the staff and workmen at the Hyde-road shed with a very massive Chippendale drawing-room cabinet, and Mrs. Blackburn with an afternoon tea service and china ornaments. The Queen's-road shed staff gave him a handsome marble clock and pair of Oriental bronze vases to match. At each gathering the men expressed regret at losing so good a superintendent, yet wished him every success at Belfast.

The Electricity Committee of the Manchester Corporation have recommended the appointment of Mr. S. L. Pearce as chief electrical engineer, for a period of three years, on the following terms : salary for the first year at the rate of £900 per annum ; for the second and third years, £1,000 per annum. Mr. Pearce is to enter into an agreement to remain in the employ of the Corporation for three years from Feb. 1, 1905, and to devote the whole of his time to the duties of the position and in carrying out any electrical extensions or works in the future that may be required, the engagement to be subject to any arrangement which the Corporation may from time to time make with consulting engineers.

Mr. E. Hatton, Salford ; Mr. H. E. Yerbury, Sheffield ; and Mr. G. Conaty, Birmingham, are the three selected candidates for the Newcastle tramways managership. We are informed that the appointment, which is worth £700 per annum, will not be made for a month.

Mr. Arthur King, Sheffield, has been appointed overhead construction superintendent to the Belfast tramways. Mr. King was formerly with the British Electric Equipment Company and in the Sheffield Corporation's tramways department.

On Monday night Mr. Sidney Herbert Thomas, the electrician-in-charge of Shoreditch electric lighting department during the absence of the chief, was the recipient of a handsome suitably-inscribed marble timepiece with statuettes in celebration of his marriage a week previously. There was a large attendance of the chief officials of the staff and employés at the depôt, among those present being Mr. George Kemp, A.M.I.E.E., second engineer-in-chief (who made the presentation in the unavoidable absence of Mr. Chas. Newton Russell, engineer-in-chief) ; Mr. Alfred Vincent, general foreman of the station ; Mr. Lawson, engineer-in-charge, Whiston-street, Hackney-road ; Mr. Sydney Fairleigh, inspector of dynamos ; Mr. J. Week ; and Mr. W. G. Hackett, chief attendant of storage batteries.

## LEGAL INTELLIGENCE.

### THE PROPOSED TRAMWAY ON CANVEY ISLAND.

The case of Bruce Peebles and Co., Limited, *v.* Hester came before the Master of the Rolls and Lords Justices Mathew and Cozens Hardy on the appeal of the defendant from an order of Mr. Justice Jelf in chambers.

The plaintiffs, a firm of electrical engineers and contractors, brought the action to recover £3,630 against the defendant as accepter of two bills of exchange, dated June 3, 1904, which bills upon presentation were dishonoured. It appeared that the defendant owned an estate on Canvey Island upon which he wished to have a tramway built, and he entered into a contract with the plaintiffs to do the work. The tramway was to have been completed by June last year, but it was not, and it was agreed that a penalty of £1,000 should be paid. Afterwards an arrangement was entered into under which the bills, the subject of the present action, were given in respect of moneys admittedly due from the defendant to the plaintiffs in respect of the work, but the defendant contended that it was a condition precedent to the bills being presented that the plaintiffs' contract had to be completed by September, 1904. Mr. Justice Jelf, in chambers, gave the defendant leave to defend on bringing into court £1,000. The defendant now appealed from this, contending that he ought to have unconditional leave to defend.

The appeal was allowed.

### NORTH-WEST LONDON ELECTRIC SUPPLY COMPANY.

In the Chancery Division on Friday last Mr. Justice Farwell heard an application arising out of the sale of the undertaking of the North-West London Electric Supply Company to the Hampstead Borough Council for £12,000. The book debts were said not to be included in that sum. A holder of 32 debentures, representing £1,600 out of an issue of £30,000, asked for the appointment of a receiver and manager. The applicant complained that the price of £12,000 offered for the company's undertaking showed an extraordinary depreciation from previous values.

The application was opposed on behalf of all the other debenture holders, who asserted that the real object of the application was to prevent the sale of the undertaking. The first mortgagees were already in possession, and a meeting of debenture holders had already sanctioned the sale.

Eventually the matter was referred to Chambers, without prejudice, and with liberty to apply to the Court.

### MOTOR TRACTION COMPANY, LIMITED.

In the Chancery Division on Friday last, before Mr. Justice Buckley, **Mr. Buckmaster, K.C.**, applied for an interim injunction to restrain the defendant company from carrying into effect an agreement, dated Dec. 9 last, purported to have been entered into between the company and the defendant, Mr. Frank Grice Hackney, as trustee for an intended new company. Counsel argued that the memorandum of association did not empower the company to sell its undertaking for shares in another company, as it was proposed to do.

His Lordship reserved judgment.

### KILLARNEY ELECTRIC LIGHTING COMPANY.

In the Chancery Division on Friday last the Master of the Rolls heard the case of the Callender Cable and Construction Company, Limited, *v.* Killarney Electric Lighting Company.

**Mr. Leet** applied on behalf of the defendants to appoint a receiver in place of the receiver at present acting for the Court. The present receiver had issued a notice that he would shut down the works of the

Digitized by Google

defendant company, and counsel stated that if this intention were carried out, the defendants would lose the benefit of the provisional order, and would expose themselves to a fine on foot of that order of £2 per day. This would be fatal to the electric lighting company, and to the possibility of a sale. If the works were to be sold, they should be sold as a going concern.

The **Master of the Rolls** adjourned the matter for a week, and intimated that he would then receive sealed tenders containing offers for the purchase of the works of the defendant company.

## OVERHEAD WIRES.

Before the Railway and Canal Commission last week the appeal of the Postmaster-General against the decision of Judge Russell, sitting at the Croydon County Court, with respect to overhead telegraph wires in the Croydon Rural Council's area was heard.

The **Attorney-General** said the inhabitants of South Bedington had petitioned to have the local post office connected by telegraph wire, but the Council would only give its consent if the wires were laid underground. To meet them the Postmaster-General proposed iron posts, 7½in. at the base, which would cost £50. It was explained that to put the wires underground would cost £132, a sum which would make the proposal impracticable. Inconvenience from the poles would be less than from the ordinary lamp posts.

The **Commissioners** announced that they would allow overhead wires at Wallington, provided light iron poles were used.

A conference then took place between the parties, with the result that an agreement was come to for the lines in Foxley-lane, Banstead-road, and Russell Hill-road to be laid underground, the Rural District Council to bear the cost of opening the trench. With regard to Selsdon-road, the Council agreed to the lines being overhead, the Council to have the right to require painted poles.

No order was made as to costs.

## MANCHESTER TRAMWAY COMPANY.

Vice-Chancellor Sir S. Hall, K.C., in the Lancashire Court of Chancery at Manchester on Tuesday, gave judgment in regard to the distribution of the surplus assets of the Manchester Carriage and Tramways Company, Limited (in liquidation) amongst the shareholders. There were three classes of shareholders—holders respectively of "A," "B," and "C" shares. The nominal value of the "A" shares was £20, with £15 paid up; of the "B" shares £10, fully paid up; and of the "C" shares £10, with £7. 10s. paid up. The question for decision was whether the distribution of the surplus money should be made on the basis of the nominal value of the shares or on the basis of the amount paid up.

The **Vice-Chancellor**, after reviewing the history of the concern, held that the surplus must be divided upon the basis of the nominal amount of the shares.

Leave was given for the immediate payment of a sum on account of about 4s. in the £ on the amount paid up.

## ELECTRICITY AND VIBRATION.

In the Lancashire Chancery Court at Manchester, the case of Barlow *v.* the Manchester Corporation came before Vice-Chancellor Sir S. Hall, K.C. The plaintiff, Mr. Barlow, is the owner of property in Dickinson-street, and he sought to restrain the Corporation from committing a nuisance to his property by vibration caused by the operations carried on at the electricity works of the Corporation in the same street.

**Counsel** for the Corporation said the action came on first for trial in February, 1903. The Corporation were then advised that by some alterations which were suggested by an eminent authority, the vibration complained of would be entirely removed. Terms were thereupon made putting the plaintiff in a favourable position. At the end of year the experiments were not completed, and as a matter of fact they were not completed till the spring of last year. The result of the experiments was a failure, and although the Corporation had spent £3,000 upon them, they had to acknowledge that there was nothing further to be done. As an alternative course, it was suggested that two large engines which, it is alleged, caused the vibration, should be taken out of the works and two turbines substituted. Contracts were entered into for the supply of the turbines, and they were promised for November last, but the contract had not yet been completed. Mr. Maberly's application now was that the trial of the action should be fixed for a date earlier than March 28.

The **Vice-Chancellor** said the plaintiff must have a reasonable time in which to observe the effect of the changes that were being made, and it was finally agreed that the trial of the action should stand over till the first Tuesday in 1906 on which witness cases are taken, the existing undertakings to be continued in the meantime.

## MIDLAND ELECTRIC COMPANY v. PARSONS AND SONS.

In the Wolverhampton County Court, Judge Howland Roberts delivered judgment in an action which was tried before him on Oct. 17. The plaintiffs were the Midland Electrical Corporation for Power Distribution, represented by Mr. R. C. E. Plumptre (instructed by Mr. Hayward), and the defendants (for whom Mr. J. Clarke, of West Bromwich, appeared) were Messrs. David Parsons and Sons, iron-founders, The Leys, Brierley Hill. The plaintiffs sought to recover £46. 19s. 3d. for electrical energy consumed by the defendants at their works between Sept. 28 and Dec. 31, 1903.

At the hearing of the action in October, Mr. Plumptre, in stating the case for the plaintiff company, said the defendants were under a contract to receive electrical power from his clients at the rate of 4½d. per Board of Trade unit. On Dec. 21 a man in the employ of the plaintiff company went to the defendants' works to take the reading of the meter. According to his reading the meter on that date registered a consumption of 770 units. He was a man of little experience in reading meters, and it was evident he had made a mistake, because on a further reading of the meter on Jan. 5 it was found to register a consumption of 1,770 units, although during the interval the works had not been in operation, and no electrical energy had passed through. There might have been a leakage owing to a defect in the installation, but the company were not responsible for that.

On the part of the defendants it was contended that they had not received the amount of electrical current for which they were brought in as debtors. Further than this, it was denied that they had ever received any communication from the plaintiffs that there was a defect in the installation.

The case was adjourned for independent expert evidence in regard to the meter, and Mr. J. B Clarke, A.M.I.E.E., electrical engineer to the Stourbridge Urban District Council, was called in to arbitrate. After careful investigation, he communicated his decision to his Honour, who pronounced the electric meter to be correct in its readings, and gave judgment for plaintiffs.

## TRAMWAY ACCIDENT.

At the Colne County Court Robert Hartley sued the Burnley Corporation for £50 for damages as the result of an accident alleged to be due to negligence on the part of the defendants' servants.

Counsel for the plaintiff stated that his client entered a car at Burnley which was proceeding to Brierfield. Being a fine night plaintiff rode on the top. When he got to Brierfield the car stopped at a compulsory stopping place, and plaintiff commenced to go down the stairway behind a young lady. When plaintiff got near the bottom of the stairway he saw a young lady on the platform. When the latter left the car the conductor touched the button and the car started. The result was that plaintiff was thrown to the platform and sustained a fracture of the left leg, as a result of which he was in bed six weeks, and was unable to follow his employment for 14 weeks. It was the duty, counsel contended, of the Corporation to afford passengers on the trams reasonable facilities for alighting.

For the defence counsel contended that there was absolutely no evidence of negligence on the part of the Corporation's servants.

After a protracted hearing the jury found for the plaintiff, for whom judgment was given, with costs.

# COMPANIES' MEETINGS AND REPORTS

## CITY AND SOUTH LONDON RAILWAY.

The half-yearly meeting of this Company was held on Tuesday under the presidency of Mr. C. G. Mott.

In moving the adoption of the report (particulars of which we gave last week), the **Chairman** remarked that the great bulk of the traffic of their line was of a permanent kind and varied very little, but unfortunately the exceptionally fine and dry weather which prevailed during the greater part of the half-year had been much against the Company, and their interests had also been affected by the active competition of the London County Council trams, which did their best by charging very low fares to draw the traffic from the underground railways. The Company had also suffered from the depression that had existed among local trades, notably the building trade, and which had resulted in the issue of fewer workmen's tickets. With all these adverse circumstances, he thought they might congratulate themselves that the falling off was not greater than it was—namely, about £1,600 for the half-year. The balance available for dividend was £27,445, and the directors recommended that the full dividend of 5 per cent. per annum be paid on the preference stocks 1891, 1896, and 1901, and a dividend at the rate of 1¾ per cent. per annum on the ordinary stock for the half-year, leaving £1,449 to be carried forward. He and his co-directors were emphatically of opinion that their line had a great future.

The report was adopted.

## EASTERN TELEGRAPH.

The sixty-fifth half yearly general meeting of this Company was held last week, Sir J. Wolfe Barry presiding.

In moving the adoption of the report and accounts (particulars of which appeared in our issue of the 20th ult.), the **Chairman** remarked that various branches of the traffic, notably that with India, showed a satisfactory increase.

**Sir J. Denison Pender**, vice-chairman and managing director, seconded the resolution, which was carried unanimously.

The retiring directors and auditors were re-elected, and a vote of thanks to the chairman, directors, and staff terminated the proceedings.

## SOUTH-EASTERN RAILWAY.

At the meeting of this Company on Monday the **Chairman** stated that they were feeling more strongly than ever the competition of the electric trams. The only way to meet this competition was by taking off a certain number of trains which had been put on for the accommodation of the working classes, and which the working classes were now leaving, and also to a certain extent partially closing some of those stations which were principally affected. Alluding to the proposed electrification by the London, Brighton, and South Coast Railway Company of the line from Peckham to Battersea Park, he

Digitized by Google

said that a portion of that line belonged to the South-Eastern and Chatham Managing Committee, which had entered into an agreement with the Brighton Company by which they would take over that portion for the purpose of the experiment. The experiment would be extremely interesting to both companies, as it would give them reliable statistics, which were at present wanting, as to the cost of working an old line by electricity.

## GEORGE M. CALLENDER AND CO.

An extraordinary general meeting of the shareholders was held on Tuesday at the Westminster Palace Hotel, when a resolution increasing the capital of the Company by the creation of 25,000 additional preference shares of £1 each was carried. The resolution was confirmed at a meeting of the preference shareholders.

## CENTRAL LONDON RAILWAY COMPANY.

The report for the half-year ended Dec. 31 states that the amount expended on capital account has been £12 665. The receipts from all sources of revenue amounted to £176,281, being an increase of £1,046, and the working expenses to £95,937, a decrease of £1,425 as compared with the corresponding period of last year, leaving a balance of £80,343 carried to the net revenue account. The total number of passengers carried during last half-year shows an increase of 131,300, and the number to whom cheap return tickets were issued was 3,084,296, an increase of 72,086, or 2·39 per cent., as compared with the corresponding period. The average receipt per passenger is 1·86d., the same as in the half-year ended December, 1903. To meet the convenience of those who desire to avoid the daily purchase of tickets, the Company in August last commenced the issue of books of 12 tickets at 2s. per book. These have been much appreciated, and are very largely sold. After providing for interest on debenture stock, and other payments, the net revenue account shows a balance of £122,579. The directors recommend a dividend on the deferred ordinary stock at the rate of 4 per cent. per annum for the whole year, and that £30,000, with interest for the half-year, be transferred to the reserve fund, bringing the total of that fund up to £61,730, the balance of £22 111 being carried forward. In the expectation that the report of the Royal Commission on London Traffic would be presented at an early date, the directors deemed it necessary to redeposit in Parliament the Company's Bill entitled the Central London Railway (New Lines) Bill, 1905, which will be submitted for the consideration of the proprietors at the Wharncliffe meeting, to be held at the conclusion of the ordinary meeting. This Bill is practically identical with that which was deposited in 1902, and approved by the proprietors, but afterwards withdrawn in consequence of the appointment of the Royal Commission. It provides for the continuation of the Central London Railway, *via* Hammersmith, Piccadilly, and the Strand, and thence to Liverpool-street and the Bank, forming, with the existing line, a complete circular route through the centre of London. The Great Western Railway Company have also deposited a Bill which, among other matters, includes provision for a station adjoining that of the Central London Company at Shepherd's Bush. They propose to deal with such portion of their suburban traffic as can be most conveniently served at this station, and the fullest facilities will be provided to enable passengers to exchange from one system to the other. This connection with the Great Western Company's Railway, in addition to those proposed with the Great Eastern, North London, and South-Eastern and Chatham Railways, gives further force to the view which the directors have previously expressed—that a continuous circular railway, with convenient exchange stations, though without physical junctions with other lines, will enable the Company to provide the public with the best, safest, and most economical service, and they, therefore, recommend the proprietors to approve the Bill. The directors have approached the Charing Cross, Euston, and Hampstead, and Baker-street and Waterloo Companies with a view to the construction of low-level subways for the exchange of passengers at Tottenham Court-road and Oxford-circus stations respectively, but nothing has yet been settled.

## LIVERPOOL OVERHEAD RAILWAY.

The report for the half-year ended Dec. 31 last, to be submitted at the meeting at Liverpool on the 14th inst., states that the gross revenue receipts amounted to £41,717 and working expenses to £31,530. The number of passengers carried during the half-year was 5,613,752, a decline of 282,751. The directors point out that this is the first time they have had to record a reduction in traffic, which has been partly due to the quiet state of trade during the early part of the half-year, but mainly caused by the competition of the frequent and rapid service of trains on the Liverpool and Southport line since its electrification. This falling off in traffic has to some extent been met by economies in the working expenses. The works to connect the line with the Lancashire and Yorkshire Railway at Seaforth are well advanced. Receipts from passenger traffic amounted to £40,837 and miscellaneous receipts and interest to £880—together £41,717—less working expenses £31,530, and interest on mortgage debentures and on calls paid in advance £4,104, leaving £6,082. To this must be added balance brought forward from June 30, 1904 (£4,052), leaving available for dividend £10,134. The directors recommend a dividend at the rate of 1¼ per cent. per annum on the ordinary shares, leaving £3,743 to be carried forward.

## WATERLOO AND CITY RAILWAY.

The gross receipts of the line for the half-year ended Dec. 31, less Government duty, amounted to the sum of £17,676, and the working expenses to £7,891, being at the rate of 44·64 per cent., as compared with 46·44 per cent. for the corresponding period of 1903. The balance available for dividend, after providing for interest on debenture stock, is £9,030, and a dividend at the rate of 3¼ per cent. per annum on the ordinary stock will absorb £8 775 leaving £255 to be carried forward. This dividend compares with 3 per cent. for the corresponding period of 1903, and will be payable on Feb. 11. The number of passengers carried during the past six months, exclusive of season-ticket holders, was 2 256 832, showing an increase of 15 968 compared with the corresponding period of 1903. The season-ticket holders on Dec. 31 last numbered 1,645, as against 1,434 at the end of December, 1903.

## DUBLIN AND LUCAN ELECTRIC RAILWAY.

The report of this Company, to be submitted at the meeting on the 16th inst., states that the receipts on revenue account from all sources are £7. 12s. 1d. less than those of the corresponding period of 1903, whil st the total working expenditure also shows a reduction of £6. 19s. 1d., the net result being practically identical. After providing for debenture interest there is an available balance of £1,425 on the half-year, out of which the directors recommend the usual half-yearly dividend on the 5 per cent. preference shares, and of a further half-year's dividend of a similar amount on the same shares, so as to clear off all arrears of dividend on those shares up to Sept. 30 last; and that £200 shall be paid to the electrical contractors, being one year's instalment to the same date on account of the sum remaining due to them for electrical equipment, and to carry forward the balance of £375.

## SMITHFIELD MARKETS ELECTRIC SUPPLY.

The report for the year 1904 states that the gross profit amounts to £6,269, compared with £6,691 last year. The net profit for the year is £4,296. 17s. 4d., to which must be added the balance brought in to the accounts from last year, £1,262. 13s. 11d., making a total of £5 559. 11s. 3d. A sum of £1,500 has been placed to general reserve fund, bringing the total at the credit of this account to £5,740, and a further £1,000 to depreciation fund. The directors now propose to deal with the balance of £4,059. 11s. 3d. as follows: by the payment of a dividend at the rate of 4 per cent. for the year, £2,400; and to carry forward £1,650. 11s. 3d. Notwithstanding an increase in the number of lamps installed, the amount of current sold in the markets has been less, owing to general economy on the part of the consumers, due mainly to the bad condition of trade. A saving has been effected in the costs of production, and the sale of current may be expected to increase as trade improves. A new boiler was installed in the latter part of last year which has increased the efficiency of working, and will be sufficient to meet extensions and additions to the Company's business for some time to come. The plant and machinery have been fully maintained out of revenue and are in good condition.

## GREAT NORTHERN AND CITY RAILWAY.

The traffic receipts for the six months ended Dec. 31 last amounted to £36,509, as against £19,354 for the previous 4¼ months. The numbers of passengers carried for the same periods, excluding season-ticket holders, were 5,227,595 and 2 711,152 respectively. The number of local season tickets issued during the half-year was 2,511. By a supplemental agreement with the contractors, the working expenses retainable by them will be calculated for the first year of working at the rate of 60 per cent. and for the second and third years at 50 per cent. of the gross receipts.

## NEW COMPANIES REGISTERED.

**British Electric Company, Limited.**—Capital, £2,000. Object: to acquire from J. C. Dear, of 8, Mortimer-street, Cavendish-square, W., the benefit of a certain existing invention relating to improvements in holders for electric incandescent lamps, and to carry on the business of manufacturers of and dealers in electrical and gas fittings, installers of electric light and gas, etc. Registered office: 8, Mortimer-street, Berners-stret, W.

### Liens Registered.

**Electrical Bleaching Company (1904), Limited, Manchester.**—Lien registered Jan. 21 for £12,000 6 per cent. debentures, part of £14,000 authorised. No trustees. Charged on the undertaking and all the property and assets, present and future, except the uncalled capital.

**Willey and Co., Limited, Gas and Electrical Engineers, Exeter and London.**—Particulars of a series of £20,000 debentures, created by resolution of Aug. 8, 1904, and covered by a trust deed dated Dec. 29, 1904 (registered Jan. 5, 1905), have been filed, pursuant to Section 14 (4) of the Companies' Act, 1900. The debentures are issued by virtue of Article 116, subject to an agreement, dated Aug. 8, 1904, with G. W. Durant, which was confirmed by resolution of preference shareholders on same date. Property charged: the company's undertaking and property, present and future, including uncalled and unpaid capital. Trustees: W. Cash, 90, Cannon-street, E.C., and E. Herbert, 6, Finch-lane, E.C.

**Electrolytic Alkali Company, Limited (Middlewich).**—Issue on Jan. 12 of £1,560 debentures, part of a series created July 9, 1904, to secure £50,000, charged on the company's undertaking and property, including uncalled capital. Trustees: Liverpool Mortgage Insurance Company, Limited, 6, Castle-street, Liverpool. Total amount previously issued of same series, £12,200.

Digitized by Google

## APPOINTMENTS VACANT.

**Chief Foreman Winder**, Messrs. Dick, Kerr, and Co. See advertisement. (The position is vacant owing to the sudden death of Mr. B. Elliott, who had been chief winder since the opening of the Preston works.)

**Various**—Electrical Mechanic, 42s. per week; Electrical Assistant, 52s. 6d. per week; London County Council Engineer's Department.

**Test-Room Assistant**, central station. Commencing salary, 30s. per week. See advertisement.

**Assistant Electrical Engineer**, West Bromwich. Commencing salary, £120 per annum. Applications to the Borough Electrical Engineer and Manager by Feb. 4. See advertisement in last issue.

**Clerks**, St. Marylebone Borough Council. Ledger clerk, at a commencing salary of £100 per annum, and a junior clerk, at a commencing salary of £50 per annum. Applications by Feb. 4. See advertisement in last issue.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Todmorden.**—The Corporation invite tenders for the supply of electricity meters. See advertisement in last issue.

**Milan.**—The Mediterranean Railways require tenders for an electric crane to be erected at Gallarate. Tenders by Feb. 10.

**Arenas De San Pedro.**—The Municipality require tenders for public electric lighting for 20 years. Tenders by Feb. 12.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Bucharest.**—The Government require tenders for the annual supplies to the Regie for lighting materials and accessories. Tenders by Feb. 7.

**Swindon.**—The Corporation invite tenders for the supply, delivery, and erection of switch panels, etc. Tenders by Feb. 21. See advertisement.

**Dublin.**—The Corporation invite tenders for the supply of arc lamp carbons to their electricity undertaking. Tenders by Feb. 23. See advertisement.

**Ilford.**—The Urban District Council invite tenders for the supply of about 2,400 yards ·4in. concentric armoured cable. Tenders by Feb. 7. See advertisement in last issue.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Kirkcaldy.**—The Town Council invite tenders for the extension of about 500ft. in length of the present East Pier. Tenders to the Town Clerk by Feb. 4. See advertisement in last issue.

**Newport.**—The Visiting (Lunacy) Committee invite tenders for the installation of fire-alarms, telephones, etc., at the county borough asylum. Tenders by Feb. 14. See advertisement.

**Bury.**—The Electricity Committee invite tenders for the supply and erection of one 500-kw. direct-current high-speed generating set. Tenders by Feb. 14. See advertisement in last issue.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Leith.**—The Corporation invite tenders for the supply and erection of one 600-kw. steam dynamo, one water-tube boiler, and one traction switchboard. Tenders to the Town Clerk by 6 p.m. on Feb. 15.

**Stockport.**—The Tramways Committee invite tenders for the overhead equipment of about four miles of electric tramway, and also for copper rail bonds. Tenders by Feb. 6. See advertisement in last issue.

**Brussels.**—Tenders are required for erection of an electric station at the goods railway station at the port. Specification No. 391 is obtainable from the Belgian Government Railways. Tenders by Feb. 8.

**Manchester.**—The Tramways Committee invite tenders for the supply and erection of a main switchboard, auxiliary distribution boards, etc., for their car-repairing works. Tenders by Feb. 14. See advertisement.

**Stockton-on-Tees.**—The District Fund, Gas, Quay, and Electricity Committees invite tenders for the several articles and stores required by them for the year ending March 31, 1906. Tenders by Feb. 10. See advertisement.

**West Ham.**—The Council invite tenders for the supply of engine-room stores, cables, integrating wattmeters, double-pole house cut-out boxes, transformers, incandescent lamps, and coal. Tenders by Feb. 6. See advertisement in last issue.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Bermondsey.**—The Borough Council invite tenders for the supply of arc lamp carbons, conduits, electricity meters, demand indicators, and mains, fuses, engine oils, indiarubber cables and jointing mateirial, lead covered cables, and meter boards. Tenders to the Town Clerk by Feb. 6. See advertisement in last issue.

**Portsmouth.**—The Corporation invite tenders for 12 months' supply of electrical and other stores, laying cables, etc., and for carting coal from steamer to bunkers at the electric lighting station, Portsmouth. Tenders, by Feb. 15, to the Manager, Electric Light Station, Gunwharf-road, Portsmouth, from whom forms of tender can be obtained.

**Christiania.**—The Government Railways require tenders for 8 000 kilos 4mm. galvanised iron wire, 5.000 kilos 3mm. ditto, 500 kilos salammoniac for Léclanche batteries, 500 carbons for ditto, and 4,000 insulators. Tenders, addressed to the office of the Administration, Jernbanetorret 8-9 in Christiania, in envelopes marked "Anbud paa Telegraf-og Telefon-materiel," to be received by Feb. 3.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply, delivery, and erection complete of one 21-kw. tramway rail return booster. Specification, conditions, and form of tender may be obtained from Mr. A. J. H. Carter, borough electrical engineer, Millgate, Stockport. Tenders, addressed to the Chairman of the Gas and Electricity Committee, Town Clerk's Office, Stockport, by noon on Feb. 15.

**Bridlington.**—The Corporation invite tenders for the installation of electric lighting (1) on the Prince's Parade, (2) in the Victoria Rooms, and (3) in the town hall. Specifications may be seen on application to Mr. J. Lomas, Electricity Works, Quay-road, Bridlington. Separate tenders, endorsed "Parade," "Victoria Rooms," and "Town Hall" respectively, to be sent to Mr. A. E. Matthewman, Town Hall, Bridlington, by Feb. 9.

**Bournemouth.**—The Town Council invite tenders for the following: Contract No. 1 (Section A) steel grooved girder rails, etc.; (B) permanent-way construction and rail bonding; (C) wood blocks and granite sett edging. Further particulars and drawings, etc., may be obtained at the office of the engineer, Mr. F. W. Lacey, M.I.C.E., Municipal Offices, Bournemouth. Tenders to the town clerk, Mr. Geo. Wm. Bailey, by 10 a.m. on Feb. 15.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**Hammersmith.**—The Council invites tenders for the supply of (*a*) arc lamp accessories; (*b*) arc lamp globes, etc.; (*c*) brooms and brushes; (*d*) carbons; (*e*) commutator brushes; (*f*) electrical goods; (*g*) files; (*h*) firebricks, clay, and lime; (*i*) gauge glasses; (*j*) incandescent lamps; (*k*) insulated wires; (*l*) lubricating oil; (*m*) metals; (*n*) meters; (*o*) oilman's goods; (*p*) packing and jointing materials; (*q*) screws; (*r*) tools; and (*s*) Welsh smokeless and other steam coal. Tenders by Feb. 8. See advertisement in last issue.

**Melbourne.**—Tenders will be received at the office of the Deputy Postmaster-General until noon on Feb. 7 for the supply and delivery of (1) 3,500 trunk-line multiple jacks, in strips of 20; (2) 1,320 yards of 64-wire wool-insulated switchboard cable. Specifications may be seen at the General Post Offices at Melbourne, Sydney, Brisbane, and Adelaide. Tenders, endorsed "Tender for ——," as the case may be, addressed to the Deputy Postmaster-General, Melbourne, may be deposited in the tender-box at the General Post Office, Melbourne, or, if sent by post, must be prepaid and registered. The deposit to be enclosed with the tender is 5 per cent. on the total amount.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess, M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

## RESULTS OF TENDERS.

**Motors.**—The Brush Electrical Engineering Company, Limited, have obtained a contract for 32 traction motors for the Birmingham and Midland Tramways.

**Leicester.**—The Town Council have accepted the tender of Messrs. Yates and Thom, at £6,062, for two boilers and boiler-house appliances at the tramways main power station.

**Pudsey.**—The Corporation have accepted the tender of Messrs. Johnson and Phillips, Old Charlton, Kent, for underground cables, boxes, and switchboard. The contract includes laying and erecting.

Digitized by Google

**Ormskirk.**—The Guardians have accepted the tender of the Hart Accumulator Company, Marshgate-lane, Stratford, London, E., for the supply of storage battery of 116 of their standard lighting type cells.

**Enfield.**—The War Office has accepted the tender of Messrs. Johnson and Phillips, Old Charlton, Kent, for the necessary rubber and paper cables, with boxes, for the electrifying of the Royal Small-Arms Factory, Enfield Lock.

**Cheltenham.**—The Corporation have given the Lancashire Dynamo and Motor Company, Trafford Park, Manchester, an order for an automatic reversible booster (Turnbull and McLeod patent), together with a switchboard for operating same.

**Belfast.**—The Electricity and Tramways Committee have accepted the tender of the Hadfield Steelfoundry Company, Limited, at £1,126, for special track work at the Sandy-row depôt, and the tender of M'Laughlin and Harvey, Limited, at £19,690, for the erection of the generating station.

**London County Council.**—The following tenders have been received for the execution of the roadwork and platelaying in connection with the construction, for the underground conduit system of electrical traction, of the tramways authorised by the London County Tramways Act, 1904, from the existing lines in Clerkenwell-road, *viâ* Rosebery-avenue and St. John-street-road, to the existing lines at the Angel, Islington :

| | | | |
|---|---|---|---|
| John Mowlem and Co., Limited, London (accepted) ... | £27,925 | 0 | 0 |
| Robert W. Blackwell and Co., Limited, London ..... | 29.149 | 14 | 6 |
| Wm. Griffiths and Co., Limited, London ..... | 29,704 | 1 | 5 |
| Dick, Kerr, and Co., Limited, London ..... | 29 924 | 9 | 10 |

| Muirhead, Greig, and Matthews, London ..... | 31,619 | 15 | 6 |

The engineer's estimate of the cost of the work was £26,432. 16s. 5d.

# BUSINESS NOTES.

## TRACTION.

**Dublin.**—The company's extension to Rathmines has been opened.

**Llandudno.**—An early start is to be made with the construction of the tramways.

**Chesterfield.**—The system has now been completed, and a satisfactory trial trip was made the other day.

**Musselburgh.**—It is reported that the company is likely to be asked to extend their system towards Newcraighall.

**Leighton-Hitchin.**—It is stated that the light railway scheme has been abandoned, owing to the opposition of certain landowners.

**Barry.**—It is reported that the Urban District Council have now resolved to apply for a provisional order for electric tramways and lighting.

**Exeter.**—At the meeting of the City Council it was stated that the generating machinery for the electric trams was practically complete.

**Raunds.**—The Urban District Council have decided to ask the County Council to have the clause relating to option of purchase inserted in the company's Bill.

**Metropolitan District Railway Co.**—The directors recommend a dividend on the 4 per cent. guaranteed stock at the rate of £1. 7s. 6d. per cent. per annum for the past half-year.

**British Electric Traction Co.**—The directors declare a half-yearly dividend on the preference shares at the rate of 6 per cent. per annum. Warrants will be posted on 15th inst.

**Rochdale.**—Major Druitt's inspection proving satisfactory, the Heybrook section was opened last week. The laying of the lines from Heybrook to Littleborough will shortly be begun.

**Swinton.**—The Urban District Council have arranged with the tramway promoters to abandon the destructor scheme, the promoters paying compensation and agreeing to complete the trams within two years.

**Ackworth and Lindsey Light Railway.**—Evidence is now being gathered by the promoters of the Ackworth and Lindsey Light Railway. The enquiry by the Light Railway Commissioners into the proposal is to be held at Barton early in March.

**Waterloo and City Railway Co.**—The directors recommend a dividend on the ordinary stock at the rate of 3¼ per cent. per annum for the half-year ended Dec. 31, 1904, carrying forward £255. The dividend at December, 1903, was at the rate of 3 per cent. per annum.

**Lincoln.**—It is probable that the Corporation will make an early commencement with its tramway scheme, the Board of Trade having intimated that a new Act is not necessary to sanction the laying of a 4ft. 8½in. track instead of the 3ft. 6in. gauge mentioned in the Corporation's Act.

**Coventry.**—At a special meeting of the company a Bill which is being promoted to secure an extension of time for the completion of the works was approved, although it was stated that in all probabilty there would be no necessity to proceed with it, as the required work might be completed.

**Cardiff.**—At a meeting of the Tramways Committee last week a discussion took place as to the advisability of running trams earlier, or to charge a fare and a half, in order to make the Sunday service remunerative. It was eventually decided that Mr. Ellis should prepare a report on the matter.

**Blackpool and Fleetwood Tramways Co.**—For the past half year the company has a surplus of £10,426 available, and a dividend of 6½ per cent. for the half-year, equal to 9 per cent. for the year, is recommended. There is put to reserve and depreciation £1,500, to general reserve £500, and carried forward £1,964.

**Valparaiso.**—The municipality has sequestrated the property of the new electric traction company for a debt of 20,000dol. owed by the old tramway company. Although both companies settled their accounts in November, a receiver has been placed in possession. The action of the municipality is of interest to foreign capitalists.—*Globe.*

**Grimsby.**—In reference to the note which appeared in our issue of Jan. 20 concerning the light railway to be promoted by the Great Central Railway Company in connection with their Immingham Dock scheme, the Rural District Council have agreed to give their support, stipulating only that the fares and freight rates be kept within reasonable limits.

**Hammersmith, etc, Railway Bill.**—At the House of Commons the Senior Examiner of Standing Orders had before him last week the Hammersmith, City, and North-East London Railway Bill. Four memorials had been lodged in the Private Bill Office alleging that this measure does not comply with the Standing Orders. Consideration was deferred.

**Derby.**—The receipts of the Corporation tramways during the four weeks ended Jan. 21 amounted to £2,399. 17s. 1d., being an increase of £1,162. 7s. 6d. as compared with the corresponding period last year. The committee recommend that the route from the Market-place to the borough boundary on the Kedleston-road should be proceeded with.

**Edinburgh.**—A sub-committee last week considered several proposals for the extension of the tramways throughout the city. The matter was referred to the borough engineer to prepare preliminary plans and report. Consideration of a letter from the National Electric Tramways Company asking consent to lay a line from Fountainbridge to Slateford was deferred.

**Plymouth.**—Sanction has been received to a loan of £6 380 for the construction of new tramways from Pound-street, through Cobourg-street, to Pennycomequick, and it is understood the work will be put in hand at an early date. The committee have decided to apply for sanction to a loan of £1,222 for the alteration of the tramways at the corner of Ebrington-street.

**Swansea.**—A *plébiscite* was taken on Tuesday to decide whether parliamentary powers should be applied for to enable the Corporation to treat next year with the Swansea Tramway Company for the compulsory acquisition of its property, subject to a lease to the company for 21 years. The poll resulted in an affirmative vote, the majority in favour numbering about 800.

**Light Railways.**—The Board of Trade have recently confirmed the undermentioned orders made by the Light Railway Commissioners : Blackpool and Fylde Light Railway (Change of name, etc.) Order, 1905, amending the Blackpool and Garstang Light Railway Order, 1901 ; North Lindsey Light Railways (Amendment) Order, 1904, amending the North Lindsey Light Railways Order, 1900.

**Brighton.**—In an article on the completion of the third year's traffic on two of the routes of the Brighton municipal tramways (Ditchling-road and Beaconsfield-road), the *Sussex Daily News* shows that, although the total of 4,769 820 passengers exhibits a decrease of 134,457 on the number carried the previous year, the reorganisation and increase of fares have led to a revenue of £20,766. 11s. 10½d., or an increase of £332. 2s. 1½d.

**Belfast.**—It is reported that the town clerk has received a letter from a local firm of solicitors announcing that proceedings are about to be taken against the mayor, aldermen, and councillors who have accepted free passes for the trams. Application will be made in the Chancery Court for an order directing the resolution of the Council granting the passes to be rescinded, and ordering the councillors who accepted passes to deliver them up.

**Croydon.**—Polling took place at Croydon on Tuesday on the question of extending the tramways, for which purpose it is proposed to borrow about £150 000. Although there was strong opposition to the scheme, the result was favourable to the project, the voting being as follows: for, 3,523; against, 3 435. It is reported that the frontagers, prominent among whom is Sir William Treloar, will appear before the parliamentary committees by counsel.

**Walsall.**—The following particulars relating to the first year's working of the municipal trams are supplementary to those given in our last week's issue : revenue £25 089 ; working expenses, £17,157 ; average revenue per mile, £1,558. The number of car miles run was 632,368 ; passengers carried, 4 514,471 ; units of power consumed, 707,654 ; average number of cars in use per day, 17 ; average speed per hour, seven miles ; average car hours per day, 13 ; average number of passengers per mile, seven.

**New York Central Railway.**—It is reported that the New York Central and Hudson River Railroad Company has placed an order with the General Electric Company of New York for 60,000 h.p. in Curtis steam turbo-alternators, consisting of eight units of 7,500 h.p each. This will be, when completed, the largest steam-turbine installation of any kind in the world, and the first large steam-turbine installation used for supplying the motive power over nearly 300 miles of track now operated by steam locomotives.

**Elland.**—The Halifax Corporation having decided not to extend their system to Elland, the latter Council are disposed to favour the scheme of a syndicate for running a line between Halifax and Huddersfield, though it would be too late to obtain powers in the coming session. It is stated that an effort is to be made by the syndicate to secure running powers over the lines of both Halifax and Huddersfield, and they propose to get over the difficulty of variation in the gauge of the lines by obtaining powers to lay down a third line in the Huddersfield borough.

**London United Tramways Co.**—The Wimbledon Urban District Council have decided to lodge with the company notice of objection to the work in Wimbledon, on the ground that the plans and sections were not in accordance with the Act, and that the company did not

Digitized by Google

comply with several requirements in the matter of footpaths, street widenings, etc. The New Malden District Council have arranged with the company to suspend opposition to the company's application for an extension of time, pending negotiations as to the widening of the railway bridge in Kingston-road.

**Heckmondwike.**—The Examiner has had before him the Heckmondwike Urban District Council Bill for proof of compliance with the Standing Orders of the House of Commons. The Bill, amongst other things, seeks to empower the Council to enter into agreements with the British Electric Traction Company for the supply of electrical energy for tramway purposes. Opposition was offered by the Yorkshire Electric Power Company, the Liversedge Urban District Council, and the Batley Urban District Council. The Examiner decided that he must report non-compliance with Standing Orders.

**Olympia Motor Show.**—On Feb. 10 the Society of Motor Manufacturers and Traders will open their automobile exhibition at Olympia. The whole of the interior of Olympia, which is now one vast hall, giving a floor space of 440ft. long by 250ft. wide, will be entirely devoted to motor vehicles, while the galleries, a quarter of a mile in circuit and 40ft. broad, will be assigned to tyres and accessories. Electric light up to about 400,000 c.p. will be available. Arrangements are now being made for 105 exhibitors of cars, 22 of heavy motor vehicles, 17 of motor boats, 2 of machinery, 13 of tyres, and 51 of accessories.

**Great Eastern Railway.**—At the half-yearly meeting of this company, Lord Claud Hamilton, who presided, stated that the decreased earnings were partly due to the depression of trade, but he was afraid the competition of electric tramways, which were not only running in every part of their district, but in many cases were running alongside their railway, was mainly accountable for the decrease. As sensible men, they could not find fault with tramways run by public companies, but what they did complain of was the competition of municipal tramways supported by the rates to which the Great Eastern Company were the chief contributors.

**Glasgow.**—At last week's meeting of the Corporation reference was made to the position of the negotiations with the County Council of Renfrew regarding the proposed tramway from Spiers Bridge to Barrhead. In reply it was stated that the negotiations had come to a deadlock. The Renfrewshire Committee would not give their consent to the order going forward, and requested that Glasgow should withdraw the rating clause and do other things that they could not agree to. The Tramway Committee undertook that if consent to the Bill going forward was given, they would agree not to lay a single yard of line until permission was accorded. The County Council, however, remained obdurate.

**Natal.**—The *Natal Government Gazette* of Dec. 13 contains notices of applications for leave to introduce Bills into the Legislative Assembly of Natal to authorise the construction and working of tramways either by electricity or other power: (1) from a connection on the south bank of the River Umgeni with the Durban Corporation tramways to Prospect Hall; (2) from a point at or near Hillary's Station to the boundary of the Bellair estate; and also to contract for the supply of electric light or electric power to the residents in the districts to be served by the said tramways. The *Gazette* may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, E.C.

**Turkey.**—It is reported from Constantinople that the syndicate associated with M. Empain, the Belgian financier who is connected with the Paris Metropolitan Railway and other electrical enterprises, has acquired from Izzet Pasha the concession granted to the latter by the Sultan for the construction of electric tramways and light and power works at Damascus. The *Frankfurter Zeitung* states that the syndicate has paid for the transfer of the concession £26,000 in cash and £4,000 in shares of the company to be formed to carry out the scheme, with a share capital of £250 000. The concession carries with it the right to utilise for the production of electrical power all the available water power within a distance of 18 miles of Damascus.

**Hastings.**—Local associations are busy in obtaining signatures to petitions against the overhead system on the front. On the other hand, Councillor Boutwood delivers a warning in the local Press against the Council involving itself in costly litigation. The two sections in which work was originally began now join, and good progress is being made with other lines. It is the company's intention to continue the Silverhill lines through Bohemia and down London-road, St. Leonards, where they will join trams from Bexhill. A large plot of land has been acquired near Ore Station, on which it is proposed to erect the main power station. The Bexhill Town Council have decided to take all necessary steps to oppose the company's Bill.

**Queensferry.**—The solicitors to the National Electric Construction Company have written to the town clerk of Edinburgh, the town clerk of Queensferry, the county clerk of Midlothian, and the county clerk of Linlithgow, formally notifying them that an application would be made in March for a provisional order to authorise the construction of tramways from Edinburgh to Queensferry. The starting point in Edinburgh would be the west end of Princes-street or the termination of the cables at Comely Bank. It was further stated in the letter that if the order was got from Parliament, satisfactory guarantees would be given that the tramways would be laid and working in the shortest possible time after sanction had been got. In the letter to the town clerk of Edinburgh it was also suggested that the current might be taken from the Corporation.

**East London Railway.**—The wail at more than one railway company meeting during the last few days has again been the competition of electric tramways. The East London Railway, however, prefers to continue its policy of sitting on the fence in regard to electrification, apparently in the hope that the Metropolitan and District Companies, who join on to the East London system at Whitechapel, will undertake the conversion of the line. It is true that the East London Company are not in a very happy state financially, but they would probably be able to raise the funds necessary for such a promising work as the electrification of the system. As one reason for not embarking on this enterprise at the present juncture, the chairman referred to the experiment of the Brighton Company in trying the overhead principle. Assuming, however, that this system proves a success, it would complicate a physical junction with the Underground lines if adopted by the East London Railway.

**Gloucester.**—In submitting the minutes of the Tramway Committee last week, Councillor Fream referred to correspondence demanding a more frequent service of cars, and gave the results of an experimental increase of the services. Periods of three weeks ending respectively on Dec. 21 and Jan. 25 were compared. In the first three weeks they had an average of 14 cars in service, and the last three weeks 16 cars. In the first period there was an average car mileage of 8,620 per week, in the second 9 176 miles per week. The average receipts in the first period were £211. 5s. 4d.; in the second, £206. 19s. 11d. The extra cars were run from 8 to 9.30 in the morning; 12 to 2.30 middle day; and 4.30 to 7 in the evening. Notwithstanding an average increase of 500 car miles per week, the gross receipts had dropped £5 per week, and the average per car mile had, of course, dropped as well—from 5·88d. to 5·41d. The time-table service had been strictly adhered to, and the suggestion that a disturbance of the times of the ordinary cars might account for the diminution of receipts was incorrect. It had been stated that it cost 3d. for every stop and restart of a car. As the average number of stops per car mile run was four, and as the total cost of energy for operating the system was only 1½d. per mile, the statement was ridiculous. A request was made that a balance-sheet of the first six month's running should be published.

**North-Eastern Railway.**—On Friday last the company received a large and influential deputation, composed of representatives of municipalities and of the passengers, in regard to greater travelling facilities, chiefly as concerned the first class passengers. Sir Edward Grey, in reply, observed that, as regarded overcrowding, the company had been trying to cope with the difficulty for some time. They admitted there had been overcrowding, and they hoped that in time this would disappear altogether. They were gradually gaining experience in the amount of accommodation required, the difficulty having been inseparable from a new system. As regarded first class compartments, the company had found it would not pay to run a whole coach for first-class accommodation. They hoped, however, that in time they would partition off part of a coach on each train for first-class passengers. This would necessitate they thought, at present, the first-class accommodation being non-smoking. As to the doors of trains opening inwards, the company had under consideration a new door which would open outwards. It would take some months before the improvements contemplated by the company for first-class passengers were carried out. Sir Edward, in conclusion, hoped that the company would remove eventually all the friction that at present existed between the public and the North-Eastern Railway.

**Llandilo-to-Lampeter.**—At a meeting of the Carmarthenshire County Council a large deputation attended in support of an application for a grant towards the preliminary expenses of obtaining a provisional order for the proposed Llandilo and Lampeter Light Railway. Mr. Dudley W. Drummond, in introducing the deputation, said they represented the parishes of Talley, Llansawel, Cayo, Llanyorwye, Pencarreg, and Lampeter. If the preliminary expenses of surveying, etc., were assured, they hoped to go with the scheme before the Light Railway Commissioners in May next. The following sums had already been promised by public bodies along the route—namely: Llandilo Rural District Council, £300; Llandilo Urban District Council, £100; Llandovery Rural District Council, £100; Lampeter Town Council, £100; and Llanybyther Rural District Council has also promised financial aid. The railway, 23 miles in length, would be a connecting link between important districts. It was to be of standard gauge. The estimated cost of the provisional order was £800, and £500 had been already voted. There was absolute unanimity amongst the public of all classes and creeds along the route, and the promoters were representative landowners throughout the district. The lowest estimate of the annual receipts to be received by the railway was £14 000, and after taking into consideration the usual estimate of 50 per cent. for working expenses, this would leave a net profit of £7,000 a year. The County Council unanimously resolved to make a grant of £300.

**Metropolitan Railway.**—At the half-yearly meeting of this company the chairman observed that electric trains were now running regularly on the railway. They had been rewarded with an increase in their traffic. They had so far completed the electrical equipment of their line as to admit of the working of a portion of their trains, between Baker-street Station and Uxbridge, through Harrow, by the new method of traction. They were gradually increasing the number of electric trains into and out of Baker-street, and they hoped shortly to be able to dispense with steam entirely on that section. On the Inner Circle the works were being pushed on, and they hoped very soon to run some electric trains on that section. He understood that the District Company were also well forward with their installation; so that they might reasonably expect, in the near future, when both companies were ready, to see the trains on the Circle driven by the new power. So far as regarded this company's section of the Circle, their contractors hoped to enable them to run a few trains as early as March. In their new electric trains they had provided two classes only, and this, of course, meant ultimately abolishing second class entirely on the Circle trains and on the trains between Baker-street and Uxbridge. They proposed at the same time to revise and reduce their first-class fares, so that they would, speaking generally, not exceed the third-class fares by more than one-half. This would apply both to single and return journey fares, and there would also be some reduction in the season-ticket rates.

**Liverpool.**—The following proposal is down for consideration at the monthly meeting of the Bootle Town Council: "That the Bootle

Digitized by Google

Corporation will in the next session of Parliament apply for a provisional order authorising them to construct the following two lines of tramways in Bootle: (1) Breeze-hill, Balliol-road, and Miller's Bridge to Regent-road; (2) Linacre-lane, from Knowsley-road, *vid* Aintree-road, to the borough boundary at Hornby-road, Walton; that such order shall contain power for the Liverpool Corporation to continue the construction of both lines and connect same with the Aintree and Fazakerley line; that such new lines shall be worked by the Liverpool Corporation in conjunction with existing tramways and for similar purposes only; that the rental provided in the existing agreement of Sept. 1, 1902, be increased in respect of the additional cost of special construction and maintenance of the Balliol-road line." Mr. Bellamy has now reported on the question of fares. He thinks a universal 1d. fare would cause much dissatisfaction as resulting in unequal value. Halfpenny fares, he considers, would entail a net annual loss of £75,000. With regard to workmen's fares, Mr. Bellamy submits that Liverpool has adopted a general fare which is below the statutory fare of ½d. per mile fixed for workmen. In conclusion, Mr. Bellamy suggests that the committee might consider whether it would not be a wise policy, having secured to the Liverpool public many advantages in their car service, to refrain for a time from experimental concessions which it would be difficult to recall, and which might prove disastrous.

**London County Council.**—The Streets Committee presented to the City Corporation last night a recommendation that the proposal of the County Council to run tramways over Blackfriars Bridge and along the Victoria Embankment for the purpose of linking up the southern tramway system be opposed. The committee arrived at this decision by a narrow majority. At the same time it is reported that Mr. Deputy Algar has been elected the chairman of the Bridge Houses Estates Committee, to which body has been referred the proposal to widen the City side of Blackfriars Bridge in order that the passage of the tramways may be facilitated. At Tuesday's meeting of the Council the Highways Committee recommended that Messrs. J. Mowlem and Co.'s tender, amounting to £27,925, for the roadwork and platelaying in connection with the line from Clerkenwell-road to the Angel, Islington, be accepted. Particulars of the tenders will be found in our usual column. The receipts for the week ended Jan. 21 amounted to £11,470 as against £8 906 last year, and from April 1 to that date the total was £538 012, against £418,907. Questioned upon the remarks made by the chairman of the South-Eastern Railway Company, the Chairman of the Highways Committee stated that so far from being aided by the rates the municipal trams of London had aided the rates to the extent of £293 592. This amount, Mr. Baker went on to explain, was handed over in relief of rates from the profits earned in the six years of working from 1897-8 to 1902-3. In addition, the interest on the loan had been paid and the debt reduced to the extent of £246 591. A further amount of debt had been paid out of the proceeds from the sale of property, horses, and fodder no longer required, and this reached a total of £93,376. "It is true," Mr. Baker proceeded, "that owing to the cost of reconstructing the lines we did not pay anything in the reduction of rates last year. We were, however, able to carry forward a credit balance of £18 565. This year the working of the lines has been so successful that when the accounts are presented we have reason to believe the Council and the ratepayers will again be highly satisfied." In addition to this it has to be remembered that the improved labour conditions under the Council represent a substantial amount, besides which ½d. fares have been introduced.

**Birmingham.**—The Tramways Committee in their report to be presented to the Council on the 7th inst. deal with the acquisition from the City of Birmingham Tramways Company, under Section 43 of the Tramways Act of 1870, of so much of the company's undertaking as is situated in the district of Balsall Heath, which district became part of the city in 1891. A proposition was made by the company in June that the Corporation should pay a lump sum, which was to include the purchase of the lines and a release from all statutory obligation to purchase rolling-stock, depôts, etc., which might arise under the Tramways Act, 1870, Section 43. The company stipulated that they should have a lease of these lines until Dec. 31, 1906, at a rent equal to the interest and sinking fund on the amount which might be agreed upon as the lump sum payable by the Corporation. The negotiation afforded an opportunity of raising the whole question of electrically equipping all the horse and steam routes under lease until Dec. 31, 1906, before the actual expiration of the leases, so that any break in the service might be avoided. At first there was a large difference between the parties as to the value to the Corporation of a concession to electrify the lines before the expiration of the lease, but the following terms have now been provisionally arrived at, the Corporation agreeing to take over the large car-sheds and repairing shops in Kyott's Lake-road: (1) The Corporation to pay to the company £220 000 for: (*a*) the lines of the Balsall Heath tramway; (*b*) full satisfaction of their statutory liability in respect of the Balsall Heath system; (*c*) the concession stated in Clause 4. (2) The Corporation to have immediate possession of the Balsall Heath tramway, and the purchase money to be paid on Dec. 22, 1906. (3) The Corporation to immediately lease the Balsall Heath tramway to the company to Dec. 31, 1906, at a peppercorn rent. (4) Immediately on the execution of the agreement, the Corporation to be at liberty to enter upon the steam routes and horse routes in lease until Dec 31, 1906, for the reconstruction thereof, and to construct crossover roads, increase or alter passing places, situation for loop, etc., and to make connections with junction to overhead equipments in accordance with a plan already signed by the managers. (5) The company to have option as to order of reconstruction, but all lines to be reconstructed by Dec. 31, 1906. (6) The Corporation to proceed with the reconstruction expeditiously, and to compensate for loss of traffic receipts consequent upon any interference with the company's car mileage in the course of reconstructing the lines, but the company to do their best to maintain their car mileage. (7) The Corporation to protect and indemnify against accidents, during reconstruction, not attributable to negligence of the company or their employés. (8) Until reconstruction, the company only to be liable for such repairs as may be sufficient to maintain the existing steam services with safety to the public; liability to cease during reconstruction, and after reconstruction the company's liability to be the same as under existing leases. (9) The Corporation to purchase the Kyott's Lake-road depôt for £16 000, and the purchase to be completed on Dec. 22 1906. (10) The company to give possession of so much of the Kyott's Lake-road depôt as is required for Corporation purposes on July 1, 1906 (this is defined by plan), and thereupon the Corporation to pay half of the purchase money. (11) The company to remove their cars, engines, etc., immediately after Dec. 31, 1906, and, in default, the Corporation to be entitled to remove and recover expense at March 31, 1907. (12) Disputes to be referred to arbitration. The committee recommend the approval of these terms, being satisfied that the cost to the Corporation would not be less if the leases were allowed to expire with no provision as to re-equipment, and that great public inconvenience will be avoided by ensuring an uninterrupted service when the transfer of control from the company to the Corporation takes effect in January, 1907.

## LIGHTING AND GENERAL.

**Barnet.**—The Herts County Council intend to oppose the Barnet electric lighting order.

**Sunderland.**—Application is being made for a loan of £15,000 for additional electric supply plant.

**Battle.**—Enquiries are being made with regard to the provision of telephonic facilities in the town.

**Cumberland Asylum.**—The proposed electrical installation at the lunatic asylum is estimated at £6 600.

**Stirling.**—Sanction has now been obtained to borrow £4,000 for the Town Council's electric light undertaking.

**Macclesfield.**—It is proposed to appoint a consulting electrical engineer to formulate a scheme of electricity supply, the cost of which must not exceed £20,000.

**Islington.**—At to-night's meeting it will be recommended that conduits and mains be laid along Holloway-road from Eden-grove to Canonbury-road, by St. Paul's-road, at an estimated cost of £2 800.

**Nantwich.**—The Urban District Council have referred to the General Purposes Committee consideration as to the steps to be taken to carry into effect the electric lighting scheme for which they were granted a provisional order in 1900.

**South Africa.**—The Village Main Reef Company have just ordered the first large electric hoist adopted for the Rand. The winder will be placed at a vertical depth of 1,100ft. The generating plant will be of 900 h.p. and the hoist of 500 h.p.

**London Electric Supply Co.**—The company have sold 10,531,785 units of energy during 1904, estimated to produce a net revenue of £65 333, and not £60,333 as previously announced. A dividend of 3 per cent. is recommended on the ordinary shares.

**Ilfracombe.**—The manager of the local electric light company, Mr. A. Alan Jenkins, arranged for an exhibition which is now being held in the Runnicleave Theatre, and where numerous appliances for electric light and power, heating, and medical purposes are on view.

**Carlisle.**—The second annual dinner of the staff employed at the electricity works was held on the 19th ult. Mr. Burnet, who presided, gave some very interesting figures of the present and past working of the electricity works, and proposed "Success to the Carlisle Electricity Works."

**Telephone Trust.**—It is announced by the New York papers that 43 telephone companies in the United States and Canada have formed a trust with a capital of £50,000,000. It is projected to run one great trunk line from New York to San Francisco, taking in the branch traffic all along the route.

**"Excello" Arc Lamps.**—We are informed that the Union Electric Company's "Excello" arc lamps are now being installed for lighting up the most important parts of the city of London. A commencement was made on Jan. 31 with lamps around the Bank of England and the Mansion House.

**Farnham.**—The Council are about to withdraw the instructions to the parliamentary agents to apply for a modification of the proposed Farnham and District Electric Supply Company's provisional order, whereby the Council would be enabled to purchase the company's undertaking in 21 years instead of in 42.

**Manchester.**—A report will shortly be submitted to the Town Council, in which Mr. Pearce recommends the following extensions to provide for their requirements of next winter: three 500-kw. motor-generators, £6 000; low-tension switchgear, £1,500; foundations, etc., £600; extensions to mains and sub-station plant, £21,000.

**Tredegar.**—At the last meeting of the District Council the letter of Mr. A. S. Tallis, suggesting that the Council should purchase electrical power from the Tredegar Company and supply private consumers, was further considered, and it was decided that a deputation representing the Council be appointed to meet Mr. Tallis upon the question.

**Ripon.**—At the meeting of the City Council on Monday night, Mr. C. Watson stated that several companies were making application for lighting orders for Ripon. The Corporation had an order in their own hands, but they would do nothing until they knew the intention of the Power and Traction Company, who had already obtained a tramway order for Ripon.

**London Gazette.**—The partnership between John Sandford and Henry W. Wartnaby Dix, carrying on business as electrical engineers at 44, Waterloo-street, Birmingham, has been dissolved by mutual

Digitized by Google

consent. The Midland Electric Corporation for Power Distribution have given notice of intended application to Parliament for power to supply electrical energy in bulk to Stourbridge.

**Brighton.**—A party of about 30 members of the Brighton and Hove Natural History and Philosophical Society paid a visit to the Corporation electricity works in North-road on Friday, the event being arranged as one of the series of winter monthly visits to places of interest. They were conducted around the works by Mr. Christie, the resident engineer, and Mr. Philpott, works engineer.

**Gloucester.**—The electrical engineer has reported that, judging from the result of the nine months' trading to Dec. 31 last, he estimated that the trading for the full year ending March 31 next would show a net profit of about £1,100 after paying instalments of interest and sinking fund. The Council are asking Mr. R. A. Chattock, M I E E., to report upon the plans and specifications for the proposed extensions at the electricity works.

**Hull.**—At the last meeting of the Corporation Electric Lighting Committee estimates were submitted by the engineer for the coming year of £36,000 on capital account. Mr. Bell considers that no further expenditure would be necessary on capital account for the next two years, but they would have to decide upon the question of changing over the greater part of the old town system to high pressure. Next year he anticipated an income of £46,887.

**Lennoxtown.**—The Postmaster-General in August last agreed to include Lennoxtown and the surrounding district in the Glasgow free-speaking telephone area, which now stretches from Blanefield and Kilsyth on the north, to East Kilbride and Eaglesham on the south, Bowling on the west, and Baillieston on the east. The National Telephone Company have just opened their Lennoxtown exchange, to which 45 subscribers are joined or are being joined.

**Grimsby.**—The last monthly report of the borough electrical engineer (Mr. W. Vignoles) shows that 2,319 more private lamps and motors have been connected, bringing the total to 42,705. Thirteen new consumers have been added. Compared with the same period a year ago, 977 more units have been sold for traction purposes, 12 more for public lighting, and 25,548 more to private consumers. Steam has been supplied to the station from the destructor works to the value of £12. 4s. 6d.

**Croydon.**—The Attorney-General has obtained from the Railway and Canal Commissioners an order authorising the Postmaster-General to lay telegraphs and telephone wires overhead on the road within the jurisdiction of the Rural District Council. The District Council had refused to consent to wires being laid unless they were placed underground, alleging the road was too narrow. The Postmaster-General is willing to provide narrow iron posts so as not to interline with the road.

**Wimbledon.**—The Urban District Council have adopted a recommendation to the effect that, considering the engine floor space available at the generating station, the plant should be extended by the addition of three 1,000-kw. turbo-alternators with condensers, that the necessary foundations be excavated forthwith, and also that a 1,000-kw. turbo-alternator with condenser be obtained and erected. The electrical engineer is to prepare plans and estimates for such foundations and a 1,000-kw. turbo-alternator with condenser.

**Removals.**—Messrs. E. P. Allam and Co., 11, Hatton-garden, E.C., inform us that, owing to rapid increase of business, they have opened larger offices, showrooms, factory, and stores at 11, Red Lion-street, Clerkenwell-road, E.C., where additional plant has been put down. They call special attention to their department for armature winding and motor repairs, and to new specialities in iron-clad motor accessories. Also due to increasing business is the removal of the General Contracts Company (the Strut Switch) to 62, Rosebery-avenue, E C.

**St Marylebone.**—A special meeting of the Corporation will be held at the town hall on 9th inst. for the purpose of taking into consideration the following Bills affecting the interests of the borough and intended to be introduced into Parliament in the ensuing session—viz.: Metropolitan Electric Supply Company (Various Powers), Central Electric Supply Company, Administrative County of London and District Electric Power Company, Metropolitan Pneumatic Dispatch Company, Baker-street and Waterloo Railway, and London Building Acts Amendment Bills.

**Thornhill.**—The Thornhill power station of the Yorkshire Electric Power Company is now practically completed, and the company have commenced to supply electrical energy. The foundations were laid down in November, 1903, and in December last not only was a supply of energy available, but 26 miles of cable were laid. The generating plant is of a capacity of 9,000 h.p., and, on account of the high pressure adopted, energy may be transmitted from the station over long distances. Contracts are already made for supply to a number of local authorities, collieries, mills, and a variety of trades.

**Halifax.**—The Mayor (Alderman E. Robinson) on Wednesday started a new generating set at the Corporation electricity works, which has been provided at a total cost of £6,631. Alderman Hey stated that this brought up their equipment to 8,000 h.p., with a capacity of 4,500 kw. They had now only a margin of one engine over the maximum demand. If the rate of consumption increased as it had done hitherto, they would before very long be compelled to extend their plant still further. The new engine was given the name of "Enoch Robinson," as a compliment to the mayor.—*Yorkshire Post.*

**Diesel Engines at St. Louis.**—We are informed that the three 225-b.h.p. Diesel engines used in the light and power installation of the St. Louis Exhibition gave excellent results. The engines ran uninterruptedly from the beginning to the end of the fair except on Sundays, when it was closed. They were direct coupled to three Bullock generators, each of 165 kw., and supplied 588,500 kilowatt-hours at a cost of 1,830·60dol. for fuel (60,120 gallons at three cents per gallon). The average cost for fuel was $\frac{3}{10}$ cent (about 0·15d.) per kilowatt-hour on the switchboard, including all generator and line losses.

**Liverpool.**—The Corporation electric supply accounts for last year show that the income on revenue account totalled £236 404, of which £135,631 was from electrical energy for lighting and power, £2,371 from public street-lighting, and £91,674 from tramways. On the expenditure side there is £65 192 for the generation of electricity, £4,752 for distribution, £16 431 for rent, rates, and taxes, and £11 455 for management expenses. The net balance amounted to £44,510, of which it has been resolved to transfer £16,285 to the reserve fund, £11,289 to the renewal fund, and £16,934. 9s. 5d. to the general rate.

**Glasgow.**—The Corporation have adopted the following recommendations of the Committee on Telephone Service: (*a*) that the present call wire system should be gradually superseded, and that in lieu thereof the automatic calling and clearing lamp system should be adopted; (*b*) that in the first place the new system should be applied to the Hillhead exchange, the probable cost of which is estimated at £1,500; and (*c*) that offers be invited for carrying out the necessary works. The general manager reported that it was necessary to extend the switchboard in the Hillhead exchange, and it was agreed to get offers for the work.

**London County Council.**—On Tuesday it was agreed to lend the Hammersmith Borough Council £18 482 for electric lighting purposes. It was reported that a loan of £7,515 to the St. Pancras Council for electric light installation and meters had been completed, and that the Treasury had approved of a term of 42 years for the repayment of a loan of £10,000 for electric light installation. Part of the lighting plant at the Education Offices is to be disposed of, and current is to be obtained from the Charing Cross and Strand Electricity Supply Company. The rearrangement of the mains will entail an expenditure estimated at £250.

**Power Gas.**—We are informed that the Tranmere Bay Development Company, Birkenhead, have placed a contract with the Power-Gas Corporation, of 39, Victoria-street, Westminster, for a gas-driven electric installation for their new shipyard at Birkenhead. The installation consists of a power-gas plant of 6 000 h.p. capacity, the larger portion of the gas generated being intended for firing furnaces. The electric generating plant comprises two 400-i.h.p. Premier gas-engines, each direct coupled to a Bruce Peebles 220-kw. dynamo, and three 250 i h.p. Premier gas-engines, each direct coupled to a Bruce Peebles 140-kw. dynamo.

**Metropolitan Private Bills.**—The following Bills have been passed for first reading: City of London Electric Lighting Company, Limited (Extension of Powers); Woolwich Borough Council; Great Northern, Piccadilly, and Brompton Railway (No. 1); Great Northern Railway; Edgware and Hampstead Railway; Charing Cross, Euston, and Hampstead Railway; Baker-street and Waterloo Railway; Metropolitan Electric Supply Company (Acton District); Whitechapel and Bow Railway; and London County Council (General Powers). Consideration of the Metropolitan Electric Supply Company (Various Powers) Bill and of Great Northern, Piccadilly, and Brompton Railway (No. 2) Bill has been postponed.

**Dartmouth.**—An exhibition will be held at the Dartmouth Subscription Rooms from Feb. 22 to 26 in connection with the Urban Electricity Supply works in the town. There will be a charge made for admission, and the entire proceeds will be devoted to the Dartmouth Cottage Hospital. A string band and the Dartmouth Borough Band will be in attendance. Machinery will be erected and driven by electrical power for sewing, drilling, printing, etc., and there will be on view the most modern appliances in regard to electric lighting, heating, etc. A room containing hospital appliances will be a special feature. The arrangements are in the hands of the company's local engineer and manager, Mr. G. E Smith.

**Edinburgh.**—The Electric Lighting Committee have adopted Prof. Kennedy's report on the proposed extension of plant at M'Donald-road station, and will recommend the Council to authorise an extension at a probable cost of £8 000. They have resolved to recommend that the department should undertake the testing of incandescent lamps at a small cost, with a view of ensuring to users of electric light in the future a supply of current through lamps which had thus been officially tested for the purpose. The number of lamps applied for in the three weeks from Dec. 29 was 5,096, compared with 2,444 in the corresponding period of the previous year. The total for the year from May 15 was 74,458, against 57,156 in the preceding year.

**Stock Exchange.**—The Stock Exchange Committee have appointed Feb. 9 special settling day for Cape Electric Tramways' further issue of 11,222 shares of £1 each, fully paid, Nos. 480,001 to 491,222. The committee have ordered the undermentioned securities to be quoted in the official list: Anglo-Argentine Tramways Company's 50,000 vendors' ordinary shares of £5 each, fully paid, Nos. 380 008 to 430,007; Cape Electric Tramways' further issue of 11,222 shares of £1 each, fully paid, Nos. 480 001 to 491 222; and South African Lighting Association's further issue of 1,000 shares of £10 each, fully paid, Nos. 7,001 to 8 000. Applications have been made to the committee to allow the following securities to be quoted in the official list: Folkestone Electricity Supply Company's 10,000 5 per cent. cumulative preference shares of £5 each, fully paid; and South Wales Electrical Power Distribution Company's 42,750 shares of £10 each, and £150,000 debenture stock.

**Aberdeen.**—The members of the Town Council on Tuesday inspected the Corporation electricity works and the extension of the subway from Holburn-street to Crown-street, under the guidance of Councillor Kemp (convener), Mr. Bell (chief engineer), and his assistants. Mr. Kemp made an interesting statement on the progress of the work during the year, and said that for the 5½ months ending Jan. 19 there

Digitized by Google

was an increase of 602,418 units of electricity generated as compared with the corresponding period last year, and that the increase in the number of consumers this year compared with last year was 173. The length of the subway was 780 yards. It took 13 months to build it, and the cost was £10,200.

**Mansfield.**—The Mansfield Woodhouse Urban District Council have appointed a sub-committee to meet the Town Council on the subject of the supply of electricity to Mansfield Woodhouse. Messrs. Hammond and Son are to be retained to maintain a general supervision over the works and to advise the Corporation from time to time upon any points that may arise for a period of 12 months, at a fee of 50 guineas and out-of-pocket expenses. The light railway company have been asked to give a guarantee to pay from May 13 next a minimum sum of £300 per quarter for current whether any is taken by them or not. Layton-avenue will be lighted by electricity, and in addition to the ½-ampere Nernst lamp already fixed in the avenue eight ¼-ampere Nernst lamps will be installed.

**An Aid to Rates.**—Mr. James Carter, the borough treasurer of Preston, in an interesting table of receipts from profitable undertakings, etc., by which rates levied in various towns have been reduced, mentions the following amounts estimated for the current year to be transferred to the borough, district, or other fund from electric light and tramways undertakings: Electric light—Bolton, £4 500; Blackpool, £2,000; Burnley, £4,100; Bury, £300; Cardiff, £3,000; Dewsbury, £1,000; Halifax, £2,500; Hastings, £1,500; Liverpool, £10,298; Nottingham, £6,000; Salford, £4,500; Southport, £2,750; South Shields, £300; and Swansea, £744 Tramways—Accrington, £150; Bolton, £2,740; Belfast, £8,500; Blackburn, £6,000; Blackpool, £500; Devonport, £584; Hull, £11,500; Leeds, £55,000; Liverpool, £32,081 (the latest accounts mentioned in another column give £16,934); Manchester, £51,000; Nottingham £13,000; Salford, £13,000; Sunderland, £4,014; South Shields, £204; West Ham, £8,000; and Wigan, £3,595.

**Printed Matter for Australia.**—In reference to letters and paragraphs that have appeared in different newspapers from a firm of London shipping agents under the above heading, we are informed that printed matter can be posted from England to the Commonwealth of Australia as hitherto without incurring the expense of cases for packing printed matter, freightage, dock and landing dues, customs entries, etc. If sent in bulk to the various States of Australia there is the cost of unpacking and the different rates of postage—*i.e.*, printed matter can be posted from England at the rate of 2oz. for ½d., but if posted in Australia the rate is the same in some of the States, but in others 2oz. for 1d. New Zealand is adopting the same principle as Australia in reference to duty on printed matter. We are informed that the British and Colonial Agencies and the Australian Commercial Agency, 75, Chancery-lane, Holborn, W.C., have made special arrangements for the posting of such matter.

**Coventry.**—The following report was submitted by the General Purposes Committee to the City Council on Tuesday: "Having considered a letter from the Coventry Chamber of Commerce with reference to the present high charges of the National Telephone Company to their subscribers, the establishment of a municipal telephone exchange, and the undesirability of the Government purchasing the undertaking of the National Telephone Company on terms which would prevent a lowering of rates now charged by that company, the committee resolved that it was undesirable that the Government should purchase the undertaking of the National Telephone Company on such terms as would prevent a lowering of the telephone rates now charged by that company to its subscribers, and that the resolution be communicated to the Postmaster-General and the member for the city." The following gentlemen have been appointed a sub-committee to obtain information from other towns where municipal telephone exchanges are established, and to report: The Mayor, Alderman Bird, Councillors Gardner, Goate, and Lee.

**Telephone Exchange Fire.**—There was an outbreak of fire at the Central Exchange of the National Telephone Company in London Wall, last Friday, which, however, was not of a very destructive character, and was very speedily got over. The fire originated in the "cable" or "wire" room on the second floor of the exchange, the same room in which a similar outbreak occurred more than a year ago, and is supposed to have been caused through the fusing of a wire by one of the gas stoves. The operators who were at work there at once went into the adjoining room, which was filled with girl operators, in order to warn them to leave the premises. The girls at once went from the building and across the road to Finsbury House, where in one of the large rooms the superintendent called the muster-roll. The whole strength of the company's staff from all parts of London was immediately concentrated on the new exchange, which has been constructed in the neighbourhood, and with the object of transferring the subscribers to these new switchboards during the night about 500 men were set to work under the superintendence of the company's engineer-in-chief, Mr. Gill, and its metropolitan superintendent, Mr. Clay.

**Hydro-Electric Plant.**—Numerous concessions and applications for concessions to take water from rivers in Spain, in addition to those mentioned in our last issue, have appeared in recent issues of the Board of Trade *Journal*. It is also reported that Signor L. Marcello Ciurlo, Genoa, has applied to the Italian Government for the appropriation of 450 litres per second from the Laccio waterfall at Torriglia for the production of power primarily for industrial purposes and eventually for electric traction. The cost of the works and machinery incidental to this concession is estimated at £25,600. There is, further, an application from Signori Curletti and Erba, Milan, for the appropriation of sufficient water from the Val Paghera and Val Pallobbia falls (Brescia) to produce 7,840 h.p. The cost of the works and machinery incidental to this concession is estimated at £32,000. The concession, which in 1900 was granted by the municipality of Rio de Janeiro to a local firm for the supply of electric energy generated by hydraulic force, was transferred on Jan. 1 to the Rio de Janeiro Tramway, Light, and Power Company, Limited. This company has been formed, with a capital of £5,000 000, by a group of American and Canadian capitalists and electricians, who have already floated other important undertakings of a similar nature in Brazil, Mexico, Canada, and the United States of America.

**Durham.**—At their last meeting the County Council discussed a recommendation and report of the Electricity Committee, and finally referred same back for further consideration. The committee recommended the promotion of a Bill in Parliament for the establishment of a system of electrical services for the county, and also the appointment of an expert to draft a working scheme, the expert to report also as to the practicability of making use of waterfalls (no particular reference to the High Force and Cauldron Snout in Teesdale) as a means of generating electricity. The report read as follows: "The area occupied by electric companies for traction and light extends over 125,921 acres. As the administrative county has an area of 638,037 acres, it will be seen that the county is less than one-fifth covered by existing companies. We find that there is comprised in the area covered by companies a population of 310,508, as against a total population in the administrative county, at last census, of 771,619. There is contained in the area covered by companies a rateable value of £1.261 283, as against a total county basis rateable value of £3,379,748, which is little more than one-third. We desire to point out that it appears from the returns that in a number of cases, districts with large rateable values and populations are only committed to companies for a short term of years, at the expiration of which they will be at liberty to join any public scheme that may have been developed by the authorities. We would point out as evidence of the rapid development of the county that between the census of 1891 and 1901 the population increased nearly 94,000. This rapid rate of growth in population seems to accentuate the need of some more popular means of transit that will disperse them over a larger area, and avoid that congestion which it is so desirable to avoid. In this enquiry we have exerted every effort to obtain reliable data as to the workings of public schemes of electric service. In one large group of public undertakings owned and managed by local authorities we found that the authorities charged their customers 1·34d. per unit less than the companies. This saving in charges aggregated to nearly one million pounds upon an invested capital of 17½ millions, equal to a return of 5½ per cent. per annum, and in addition to this great saving in charges they earned a commercial return of 6·14 per cent., or nearly ¾ more than the companies. This difference was due to two great causes: first, the authorities saved the huge sum of £472,344 in working expenses as compared with the scale of working expenses prevailing with the companies; second, in consequence of selling their electricity at so much less per unit the authorities sold an extra volume of electricity, which brought them an extra income of £585,222 as compared with the scale of sale by the companies for the same plant. Those two large items of economy and extra sale made up the considerable total of £1,057,568, so that the authorities really earned their business profit from those two main sources, and hence were able to sell their products for a million pounds less to the public. Having collected such a mass of general and local information upon the subject we as a committee were authorised to investigate, we think we are fully justified in asking the Council to empower us to have an expert report as to the practicability of a county scheme of electric services."

**Poplar.**—The Borough Council have decided that Glengall-road, Millwall, be lighted throughout with 15 arc lamps, at an estimated cost of £375, and that an agreement be entered into with the Millwall Dock Company for the placing of four of the lamps in the private road of the company. With regard to the cost of the electricity undertaking, the *East end News* stated that at the last Council meeting the Finance Committee reported, with regard to the Council's instruction to the borough treasurer to transfer the ascertained profits of the electricity undertaking to the general funds of the Council, and the instructions to the Finance Committee to use such funds for the purpose of lowering the cost of the public lighting in the borough, and of assisting the rates during the present period of financial strain, that the Electricity Committee had submitted to them the following report of the borough electrical engineer on the subject, with an expression of opinion that no money should be transferred to the general fund from the present credit balance of the electricity undertaking: "With reference to the above, I beg to bring before you, in as concise a form as possible, what I trust you will consider sufficient reasons for withholding this sum from the relief of the rates at the present time: loans accounts—1901-1902, deficit £383, borrowed capital £135,810, repayments deferred £2,279, repayments made £34. 16s. 5d.; 1902-1903, surplus £3,908, borrowed capital £28,170, repayments deferred £3,362. repayments made £168. 5s. 6d.; last year (1903-1904). surplus £2,984, borrowed capital £9,953, repayments deferred £3,707, repayments made £803. 7s.; present year (1904-1905), borrowed capital £45,000, repayments deferred £1,777. repayments due £3,044. 18s. 2d. Total: borrowed capital, £218,933; repayments deferred, £11,125; repayments made, £1,006. 8s. 11d.; repayments due, £3 044. 18s. 2d. If the repayments had not been deferred for 1901, 1902, and 1903, we should now have a deficiency on account of revenue amounting to £2,455. 8s. 7d., instead of a surplus of £6,892. 13s. 5d. The repayments of loans this year amount to £3,044. 18s. 2d., as against £803. 7s for last year, an increase of £2,241. 11s. 2d., and, in addition, the amount of repayments deferred until next year is £1,777. The repayments on loans next financial year (1905-1906) on money already borrowed will amount to £4,362. 13s. 6d., as against £3,044. 18s. 2d. for this year, an increase of £1,317. 15s. 2d. The above statement does not deal with any public lighting capital, this having been transferred to the general borough fund account from April 1 last. In view of the reduction in price of public lighting, which already represents up to Sept. 30 a saving to the borough of

Digitized by Google

£1,048. 12s. 7d., the reduction in power rate to consumers, which I estimate will reduce the revenue by approximately £700, and the statement of accounts to September last which my predecessor presented to you, and which showed a loss on the six months' working of £2,235. 15s. 1d., I do not consider it at all advisable to assume that the gross profits this year will meet all our liabilities on account of capital charges; therefore we must be prepared to pay the repayments of loans stated above out of the surplus to March last, and, after doing this, we shall only have a small credit balance for general working purposes and for providing a reserve fund, which the Board of Trade state should equal 10 per cent. of the capital expenditure, and to answer any future deficiency or meet any extraordinary claim." The report was adopted, and the reference to the committee discharged.

## PROVISIONAL PATENTS, 1905.

JAN. 20.

1136. **Improvements in or relating to electrical condensers.** John Rymer-Jones, 111, Hatton-garden, London.

1153. **Improvements relating to current-collecting devices of electrically-propelled vehicles.** Oscar Howard Baldwin, Westinghouse-building, Norfolk-street, Strand, London.

1154. **Improvements in or relating to devices for supplying current to electrically-operated vehicles.** Oscar Howard Baldwin, Westinghouse-building, Norfolk-street, Strand, London.

JAN. 21.

1169. **Improvements in and relating to magnetic separators.** William Simm and John Shuttleworth Sellers, 9, Tempest Hey, Liverpool.

1173. **A system of electric current generation.** Frederick Henry Loring, 7, Doughty-street, London.

1190. **Electric igniter for motor gas-lamps.** Frank Griffin Carter, 55, Upper-street, James-street, Brighton.

1221. **Improvements in electric meters.** Claude William Atkinson, 1, Queen Victoria-street, London.

1224. **Improvements in and relating to trolley retrievers for electric tramcar and the like.** Charles J. Earll, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

1231. **Apparatus for operating gas-taps and electrically igniting the gas.** James Grieve Lorrain, Norfolk House, Norfolk-street, Strand, London. (Société Anonyme des Allumeurs-extincteurs Automatiques, Switzerland.) (Complete specification.)

JAN. 23.

1243. **An improved clip or apparatus for the screwing up or the removal of the nut or ring used for securing the shade or reflector to electric lampholders.** John Parry, 32, King-street, Dudley, Worcestershire.

1247. **Improvements in conduits for the protection of electrical conductors.** David Maxwell, 41, Reform-street, Dundee.

1249. **Electric relay with time control for closing circuits of electromagnets.** James Ferguson and Kelvin and James White, Limited, 154, St. Vincent-street, Glasgow.

1281. **Improved devices for use in controlling polyphase and alternate current motors.** Siemens Bros. and Co., Limited, and Hereford Berry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

1299. **Improvements in or relating to apparatus for use in recording telephonic messages or sounds.** Hans Starcke, 111, Hatton-garden, London. (Complete specification.)

1300. **Improvements in or relating to electric switches, controllers, and the like.** Arthur Burgess Soar and Henry Frank Joel, jun., 111, Hatton-garden, London.

1308. **Improvements in magnetic ore separators.** Henry Charles Jenkins, 18, Southampton-buildings, Chancery-lane, London.

1313. **Improvements in electric meters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

1321. **Improvements in and relating to railway electric signals.** Slaughter William Huff, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JAN. 24.

1335. **Improved brackets or holders for the brushes or carbons of dynamos or motors.** William Thomas Thorley, Longport, Stoke-on-Trent, Staffordshire.

1360. **Apparatus for producing electric arcs, sparks, or flames for bleaching or sterilising purposes.** William Cramp, 7, Sellous-avenue, Harlesden, London.

1380. **Improvements in telephone selecting mechanism.** William David Watkins, John Wesley Bolster, and William Edward Goodsell, Norfolk House, Norfolk-street, Strand, London. (Complete specification.)

1384. **Improvements in electric apparatus for felling trees or sawing wood.** Thomas Oscar Wilson, 36, Chancery-lane, London. (Date applied for under Patents Act, 1901, Jan. 30, 1904, being date of application in the United States.) (Complete specification.)

1389. **A new electro-therapeutic ray tube.** Alfred Charles Cossor, 54, Farringdon-road, London.

1391. **Improvements in systems of electrical distribution.** Ray Philip Jackson, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 6, 1904, being date of application in United States.) (Complete specification.)

1399. **Electric governor.** James Robert Fyfe Smith, 2, East Sheen-avenue, Mortlake, London.

1400. **Improvements in incandescent electric lamp sockets.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

1406. **Improvements in and relating to the manufacture of plates for secondary electric batteries.** Louis Nestor Joseph Roselle, 7, Southampton-buildings, Chancery-lane, London.

1407. **An improved process of and apparatus for the manufacture of plates for secondary electric batteries.** Louis Nestor Joseph Roselle, 7, Southampton-buildings, Chancery-lane, London.

1413. **Improvements in electric and magnetic appliances.** Illius Augustus Timmis, Edgar William Timmis, and John Robert Cook, 2, Great George-street, Westminster, London.

1421. **Improvements in or relating to the manufacture or production of carbons suitable for use in electric arc lamps.** Vivian Byam Lewes, 46, Lincoln's-inn-fields, London.

1430. **Improvements in the method of compounding alternators.** Sautter, Harlé, et Cie, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 4, 1904, being date of application in France.) (Complete specification.)

1432. **Improvements in and relating to telephone directories.** Charles Alexander Pomeroy, 322, High Holborn, London. (Complete specification.)

JAN. 25.

1482. **Improvements in electrical contact makers and breakers.** Percy Warren Noble, 18, Hertford-street, Coventry.

1493. **Improvements in electric time switches.** James Joseph Coachman. Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

1507. **Improvements relating to electrodes for arc lamps.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (La Compagnie Générale d'Electricité, France.) (Complete specification.)

1522. **Improvements relating to distributing boards for electric installations.** Frederick Hagger Headley, 322, High Holborn, London.

1526. **Improvements in or relating to coils or windings for transformers and other electrical apparatus.** Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

JAN. 26.

1552. **Electric fans.** Wallace Fairweather, 65, Chancery-lane, London. (Diehl Manufacturing Company, United States.) (Complete specification.)

1553. **Method of drying hygroscopic insulation of electric conductors.** George Hinde Nisbett, 65, Chancery-lane, London. (Complete specification.)

1559. **Improvements in gas lamps and electric lamps.** John Baker Colbran, 58, Chiswell-street, Finsbury, London.

1560. **Improvements in dynamo-electric machines.** Arthur Serveau, 7, Staple-inn, London. (Date applied for under Patents Act, 1901, Jan. 26, 1904, being date of application in Belgium.) (Complete specification.)

1563. **Improvements in electrical measuring instruments.** Michael Birt Field, St. John's House, Sevenoaks, Kent.

1589. **Improvements in and relating to electric train-lighting systems.** The Union Elektricitäts-Gesellschaft, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Jan. 27, 1904, being date of application in Germany.) (Complete specification.)

1592. **Improvements in and relating to brush-holders for dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

1607. **Alarm fuse for telephone exchanges.** Edward B. Craft, 24, Southampton buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Feb. 5, 1904, being date of application in United States.) (Complete specification.)

JAN. 27.

1637. **An electromagnetic purifier for use in milling.** John Lawson Lawson, 34, York-place, Edinburgh.

1638. **Improvements in or relating to the "party line" system of telephones.** Harry Benwell Stocks, 5, John Dalton-street, Manchester.

1658. **An improved electromagnetic switch for use in connection with electric railways on the sectional conductor system.** Edmund Fenton, 33, Chancery-lane, London.

1677. **Improvements in arc lamps.** John Morecraft Wellington and Walter Francis Daniell, 88, Chancery-lane, London.

Digitized by Google

**1670. Improvements in alternating electric current motors.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**1681. Improvements in insulators for electric conductors.** Marconi's Wireless Telegraph Company, Limited, and George Elliott Turnbull, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JAN. 28.

**1710. Improvements in electric incandescent lamps.** Charles James Hall and Frederick John Anson, 10, East-parade, Leeds.

**1732. Improvements relating to controller and brake mechanism for electrically-driven road vehicles.** Stuart Arthur Russell and Edward Ford, 6, Breams-buildings, Chancery-lane, London.

**1754. Improvements in electric ignition devices for explosion engines.** Henri de la Valette, 4, South-street, Finsbury, London. (Date applied for under Patents Act, 1901, Jan. 28, 1904, being date of application in France.) (Complete specification.)

**1756. Improvements in and relating to electric time switches.** Norman de Maid Watsham, 1, Queen Victoria-street, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published Feb. 16.*

1904.

**1860. Conductors of electric railways or tramways.** Boardman.

**2285. Apparatus for polarisation of Hertzian waves.** Green. (Date applied for under International Convention, Jan. 29, 1903.)

**2288. Electric signalling apparatus for tramways and railways.** Wilson and Marshall.

**2450. Controlling electric switches and cut-outs.** British Thomson-Houston Company, Limited. (General Electric Company.)

**4874. Trolley poles for cars electrically propelled on the overhead system.** Kilbourn and Flower.

**5582. Electrostatic wattmeters or watt-hour meters.** Wilson.

**5731. Electrical regulating devices applicable to clocks.** Howorth. (Actiengesellschaft "Magneta" Electrische Uhren ohne Batterie und ohne Contacte.)

**6792. Method of preliminary treatment for electric accumulator plates.** Leitner.

**6857. Electrical switching apparatus.** Dick.

**6878. Electrical ignition apparatus.** Eckstein and Coates.

**7061. Electro-depositing apparatus.** Leeds Cooper Works, Limited, and Jobling.

**7217. Magneto-electric machines.** Simms.

**8189. Bayonet joint for electric lamps and other articles.** Barlow.

**9964. Electrical percussive drill.** Centner.

**13463. An electric block signal system.** Werner.

**19525. Electromotors.** Baumann. (Date applied for under International Convention, Sept. 12, 1903.)

**22494. Device for preventing broken trolley wires on electric tramways from falling.** Kirwan and Quanay.

**26262. Magnetic separating apparatus.** Scholl.

**27060. Electric switches and electromagnets therefor.** Lindquist.

**27096. Electrical signalling apparatus, particularly applicable to fire-alarms.** Abel. (Siemens und Halske Akt.-Ges.)

**27114. Operating gear for moving the rail points and conductor points or switches on electric and other tramways.** Virgin.

**27862. Electric accumulators.** Gardiner.

**27903. Secondary batteries and grids therefor.** Gardiner.

**28123. Counting apparatus for electric current, gas, water, or similar meters.** Biermann.

**29658. Terminals for electric conductors.** Renault. (Date applied for under International Convention, May 2, 1904.)

## NOTES.

**Personal.**—The President of the Board of Education has appointed Prof. Henry Adams, M.I.C.E., late of the City of London College, to be a member of the Board of Examiners at South Kensington in the engineering section.

**Royal Institution.**—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the Duke of Northumberland, president, in the chair. Lieutenant-Colonel H. E. Gaulter, Mr. E. P. Harvey, Mrs. Ludwig Mond, Dr. Tcherniac, and Dr. Evelyn C. B. Wilbraham were elected members.

**Electrical Contractors' Association.**—A special meeting of the London section of this association is to be held at Frascati's to-night, commencing at 8 o'clock. A paper on the wiring clause of the London County Council's Bill, to which we referred recently, will be read, and signatures to a petition in opposition to the measure will be invited. The association hope to have a large gathering.

**Wireless Telegraphy.**—The London, Brighton, and South Coast Railway Company began last week a series of experiments in wireless telegraphy between Newhaven and Dieppe. The results are stated to have been very satisfactory, and if further tests prove satisfactory, the system adopted, that known as the Mors, will be in regular operation in a few days' time. It is only for the private purposes of the company, the Government having granted the privilege to that extent.

**Calcium Carbide.**—At Monday's meeting of the Thames Conservancy a communication from Messrs. Anderson, Anderson, and Co. in reference to the transport of calcium carbide from Norway to Australia was discussed. A large trade is carried on between these countries, the chemical having hitherto been exported by way of Hamburg owing to the restrictions imposed on British vessels by the authorities. The Conservators have now decided to allow calcium carbide to be conveyed on ships carrying explosives, and it is expected that this will enable London to secure the trade.

**Leeds Section.**—This local section has made arrangements for its second annual dinner, which will be held at the Hôtel Métropole, Leeds, on Friday, the 3rd prox., Mr. W. Emmott, the local president, in the chair. The president and secretary of the parent institution, in addition to the presidents of other local sections, will be present. The Council trusts that all members will make every effort to be present, so as to render the gathering fully representative. Tickets, price 6s., may be obtained from Mr. G. R Blackburn, the hon. secretary, to whom early application should be made, so that seating accommodation may be arranged accordingly.

**North-East Coast Institution of Engineers.**—We have received the January number of this institution's *Transactions*, which contains the presidential address of Lord Armstrong. In the course of his address Lord Armstrong remarked that the substitution of electricity, generated in large central power stations, for the small steam-engines installed in various works, has probably reduced the total consumption of coal per available horse-power by 50 per cent. There is also Mr. W. R. Cummins's paper on "A Comparison of Vertical and Horizontal Tubes in Water-Tube Boilers," of which we gave an abstract recently, and the discussion on same.

**Yorkshire Electric Power Company.**—We learn that the Thornhill power station of this company is now practically complete, and the company have commenced the supply of energy. The foundations were laid down in November, 1903, and in December of last year a supply of electricity was available and 26 miles of cable laid. The generating plant consists of three 1,500-kw. turbo-generators and three 200-kw. direct-current exciters. Three-phase current is generated at 11,000 volts, and direct current at 230 volts. Contracts are already made for supply to a number of local authorities, to collieries, mills, and a variety of trades. A more detailed description of this undertaking will probably appear in our columns at an early date.

**Canadian Duties.**—We have received a list of the goods which the Canadian Customs Department have declared to be exempt from special or, as it is generally termed, "anti-dumping" duty. It does not comprise all the goods that may be exempt, but only those on which decisions have been given. Amongst these we notice boiler plates, flange plates, and fire-box plates, when used only in the manufacture of boilers; universal mill or rolled-edge bridge plates when imported by manufacturers of bridges for that purpose; rolled-edge plates, not less than ¼in. thick and over 15ft. long, when imported for tyres of traction engines; flat galvanised sheet iron; steel beams, tees, girders, for structural purposes, when not punched, drilled, or in any further stage of manufacture than as rolled; double tape fuses; bicarbonate of soda; rubber brushes; peroxide of hydrogen; hydrozone. In most cases the goods have to be formally declared in order to secure the exemption.

**No Embankment Trams.**—At one time the opinion was current that the Streets Committee of the City Corporation would this time report favourably upon the London County Council's embankment scheme. This, however, proved erroneous, as the committee resolved to recommend that all necessary steps be taken to oppose the measure, albeit this decision was only arrived at by a majority of one. On the report coming before the Common Council last week various amendments were proposed and rejected, and finally the committee's recommendation was adopted by an overwhelming majority. The objection to the scheme on the score of traffic congestion was supplemented by questions of motor omnibuses and the construction of a line by the Corporation itself. Apart from any consideration of the thin end of the wedge, we think the Corporation have acted advisedly for the reasons which we stated in an article a few weeks back. Presumably the Council's Bill will again be fought out in Parliament.

**Junior Institution of Engineers.**—A paper was presented to the members of this institution last week at the Westminster Palace Hotel, by Prof. H. T. Davidge, on the subject of "Recent Developments in Electric Lighting." The lecturer ran through the whole range of electric lamps from incandescents to high-frequency lamps without wires. Descriptions were given of arc, electrolytic, mercury vapour, cathodic bombardment, and high-frequency lamps without wires, and specimens of recent types were exhibited. Tables of relative efficiencies were duly submitted to the audience, and the lecturer traced out the general improvements in the various lamps. These, however, are well known to our readers, and there is no need to recapitulate them. A discussion followed, and in replying thereto Prof. Davidge stated that the proprietors of the Cooper Hewitt lamp and Mr. Bastian were endeavouring to obviate the objection to vapour lamps on account of the peculiar colour of the light by introducing red rays into the tube. The chairman (Mr. Cutler) humorously remarked that, having had a paper on gas at the previous meeting, followed by Prof. Davidge's paper on electric lighting, he hoped they would next have one on the combined subjects, as whenever he heard a gas paper he was told that electric lighting was nowhere, and *vice versâ*.

**New Publications.** — The "Manual of Electrical Undertakings and Directory," by Emile Garcke (London: The Electrical Press, Limited. 15s.). The 1905 volume of this well-known reference book is in the press, and will make its appearance in a few days. This makes the ninth year of publication, and, despite the general trade depression and the concise form of the information, the latest volume will contain an addition of 200 pages, bringing the total up to some 1,700 pages. The number of undertakings about which particulars are given approximates to some 2,400 against 200 in the first volume, while the amount of capital issued in connection with these undertakings (which include both municipal and joint-stock enterprises) has risen from a little over £61,000,000 to close on £267,000,000. The arrangement of the statistics and other material remains substantially in the convenient form adopted in previous volumes. There are also several special articles on such subjects as the London Traffic Commission, the inter-running question, and municipal telephones. The financial section has been brought up to date, and a highly useful feature included in the new volume is a number of urban and inter-urban tramway maps.

**Single-Phase Motors.**—From information we have just received it is evident that single-phase motors are coming greatly into use in connection with the electricity supply station at Burton-on-Trent. Last year an electrical exhibition was organised in the town, and this has done a good deal in the way of educating the inhabitants as to the possibilities of electric motors. Amongst the recent contracts which Mr. P. J. Pringle, the borough engineer, has secured is the electrification of a sawmill, where over 70 h.p. of motors are now being laid down. In this case the steam-driven plant will be entirely displaced by the electric motors, which will consist of two 30-h.p. Siemens-Schuckert motors and one 10-h.p. and one 1-h.p. Fuller-Wenstrom motors. These single-phase motors are to be used for driving circular saws, planing machines, etc. In other parts of the town equal success has been obtained with this type of motor. In one large stores a 4-h.p. Langdon-Davies motor has been so successful in driving a hoist that further motors with an aggregate of 22 h.p. are being put in as extensions. Including applications on hand the station has now to deal with over 270 h.p., whereas some 15 months ago the motor load amounted to only 60 h.p. This extension with the single-phase system speaks well for the efforts of the engineer-in-charge, who has in this way increased the total load at his station by over 35 per cent. in 12 months.

**Incandescent Lamp Trials.**—At the request of the commission which is now considering the future policy of electrical distribution in Paris, Mr. P. Janet has carried out a series of trials on the incandescent lamps for 110 and 220 volt circuits respectively. The experiments have been made in the laboratory of the Société Internationale des Electriciens on lamps of 5 c.p., 10 c.p., and 16 c.p. respectively. Five different makes of lamps were tried for high voltage. The results of these trials are interesting, and they will be presented in detail to the society. They remind us, however, of the fight which raged three or four years ago in this country over the conversion from the declared pressure of 110 volts to 220. The mean figures attained are somewhat as follows: With the 110-volt lamps the average consumption of energy was 3·6 watts per candle at the commencement, and after 200 hours 3·87 watts per candle. The 220-volt lamps required at the commencement of the trials 4·4 watts per candle, and 5·19 watts per candle after 200 hours. The increase in the watts per candle during the first 200 hours is thus 7 per cent. for 110-volt lamps, and 18 per cent. for 220-volt lamps. Without more information as to the type of lamp and the conditions of trial, it is not possible to criticise these figures fairly, but they seem to us to be high. It would be more economical, having regard to the high price of current in Paris, to run the lamps at a higher efficiency and with a shorter life.

**Liability for Accidents.**—Presumably the last of the Sheffield Corporation's now historic by-law limiting liability for accidents to £25 was heard last week, when the Lord Chief Justice, with Justices Kennedy and Ridley, quashed the conviction of the Sheffield stipendiary against Mr. Muir Wilson. It will be remembered that Mr. Wilson, a member of the Corporation, disputed the legality of the by-law, and, in order to test the same, he refused to produce a ticket to the inspector when travelling on a car, for which a nominal fine was inflicted upon him. Subsequently the Corporation withdrew the unpopular clause, and the proceedings last week were of little more than a formal character. While we are glad to see this clause has been disposed of, the ground on which their lordships quashed the conviction is worthy of note. When a ticket was tendered to Mr. Wilson he allowed it to fall at his feet, and refused to pick it up when requested by the inspector. The Court held that the magistrate's decision was wrong, since Mr. Wilson had not refused to let the inspector have the ticket, and it was open to the inspector to pick it up himself. Lord Alverstone elaborated the point by imagining the case of a lady who had accidently dropped her ticket, which his lordship hoped the inspector would have the courtesy to pick up for her We hope so too; but since Mr. Wilson avowedly let his ticket fall on purpose, the cases scarcely seem analogous, and the precedent does not look very favourable to tramway management.

**Olympia Motor Exhibition.**—The motor exhibition to commence at Olympia to-morrow, which will be the third exhibition of the kind promoted by the Society of Motor Manufacturers and Traders, is expected to be the largest and finest show of motorcars, motor vans, and motor boats ever held in this country, and promises to rival in importance the great annual French exhibition. As an international show it will excel that held in Paris, for not only will the bulk of the British makers exhibit, but every country which manufactures automobiles will be represented. The great building, Olympia, which has been adapted for the show at a cost of several thousands of pounds, will be literally filled with the latest and finest products of motor engineering both for pleasure and practical business purposes. The comfort of the public has been studied in every way, so that visitors will be able to spend a most enjoyable afternoon at Olympia. Music will be provided by Lieutenant Charles Godfrey's band, and J. Lyons and Co., Limited, will undertake the catering. Trials of exhibitors' cars are arranged for, whilst there is ample room on the Hammersmith side for motorcars belonging to visitors. The exhibition, which is under the patronage of the Prince of Wales, and officially recognised by the Automobile Club, is easily accessible from all parts of London. The charge for admission will be 1s., except on Thursday, 16th inst., which is the Automobile Club day, when 2s. 6d. will be charged up to 5 p.m. Reference to the scope of the exhibition was made in our last week's issue.

**Physical Society.**—At the meeting of this society last week Dr. R. S. Willows read a paper on "The Action of a Magnetic Field on the Discharge through a Gas." It had been shown previously that a transverse magnetic field, if applied at the cathode, may in some cases reduce the potential difference at the terminals of the tube. It was

Digitized by Google

shown in the paper that the pressure at which this decrease commences corresponds to the pressure at which the voltage required to maintain this discharge under normal conditions is a minimum. This was also found to be the pressure at which the positive column is first completely striated, reasons why such action takes place being given. A paper on "The Action of Radium on the Electric Spark," by Dr. R. S. Willows and Mr. J. Peck, was also read. In certain cases the authors had found that the spark from a Wilmshurst machine is extinguished by the action of the radiations from radium, and that the current passing is decreased. The action is altogether different according to the direction of the discharge. Using a spark-gap longer than 2cm., and making the larger knob of the machine used positive, the radiations had practically no influence. With the smaller knob positive, the radium in most cases extinguished the spark. The phenomenon is found to be due to the action of the $\beta$ rays. Röntgen rays do not produce this effect, even if their ionising power at the spark-gap is some thousand of times greater than that of the radium. Lenard rays are, however, effective. Prof. F. T. Trouton expressed his interest in the paper, and referred to the fact that the action of the radium depended upon the direction in which the current was passing, of which he could see no obvious explanation.

**Electrically-Driven Hydraulic Pump.**—On the 25th ult., Mr. F. W. Steele read a paper before the Liverpool Engineering Society on the design and work of hydraulic pressing, stamping, forging, and similar machinery. In his paper the author deals with the design of heavy hydraulic presses for forging and welding processes. With these presses we are not intimately concerned as electrical engineers. The supply of these presses with water under heavy pressure can, however, be effected by means of motor-driven pumps. When this is the case the pump motor needs to be controlled from the hydraulic accumulator, and Mr. Steele describes the following arrangement as being most satisfactory. The automatic starting gear used for the motor is of the solenoid type, consisting of a main switch and a solenoid multiple-step switch. The solenoid actuating the main switch is energised as soon as the hydraulic accumulator sinks low enough for a tappet switch to close the solenoid circuit. Immediately this is done the main switch is closed and current is supplied to the motor through a number of external resistances connected in the armature circuit. At the same time current is supplied to the solenoid of the multiple-step switch, the speed of movement of which can be regulated by means of a dash-pot. As this switch moves over the contacts it closes successively by means of other solenoids subsidiary switches, which cut out the different sections of the external resistance in the main circuit. This solenoid type of control answers its purpose well, allowing the motor to be brought gradually up to full speed. The pumps then continue to supply the accumulator until it rises to such a point as to open the solenoid circuit. All the switches are then opened and the motor stops.

**Electrolysis of Solutions of Copper Sulphate.**—In the *Zeitschrift Elektrochemie* Messrs. F. Foerster and G. Coffetti contribute an article upon this subject, of which an abstract appears in the *Journal* of the Chemical Society. Referring to the discovery by Bose of two cathodic decomposition points in solutions of cupric salts, the authors describe some experiments which show that at cathode potentials below the upper point cuprous oxide is deposited from neutral solutions of copper sulphate, and cuprous sulphate is formed in acid solutions. The phenomena are best observed in hot solutions, because the concentration of the cuprous ions in equilibrium with cupric ions is greater at higher temperatures. The observations are best explained by assuming that the reaction $Cu^{\cdot\cdot} - F = Cu^{\cdot}$ takes place at the cathode so long as the solution in contact with it contains less than the quantity of cuprous ions corresponding with the equilibrium $2\,Cu^{\cdot} \rightleftarrows Cu + Cu^{\cdot\cdot}$. Cuprous ions are constantly removed from the neutral solutions by hydrolysis (owing to which cuprous oxide is precipitated), and from acid solutions by oxidation by atmospheric oxygen. At a copper anode, similarly, the copper dissolves in the cuprous condition until equilibrium is attained, and since the layer of solution in contact with the anode always contains more cupric sulphate than the body of the solution, a greater number of cuprous ions will be formed there than can exist in the more dilute mass of the liquid, and, therefore, as the concentrated solution diffuses away from the anode, copper must be deposited. This explains the fact that the loss of weight of the anode is greater than the gain of weight of the cathode, and also the presence of copper dust in the anode slime.

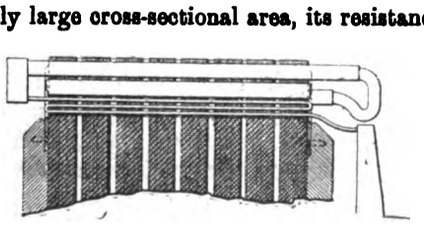
**Electrolytic Iron.**—This subject is dealt with by A. Skrabal in the *Zeitschrift Elektrochemie*, and an abstract of his paper appears in the *Journal* of the Chemical Society. Electrolytic iron of type A is white, compact, and extremely hard. It is obtained by electrolysing a solution of a ferrous salt with an iron anode and a small current density. Type B is greyer in colour, less compact, and softer than type A. It is obtained by using a platinum anode, a large current density, and a solution of some complex ferrous salt. Between these two extremes there is a series of intermediate qualities of iron obtained by combinations of the conditions mentioned. Iron of type A (obtained by electrolysing a solution of very pure ferrous ammonium sulphate with a platinum cathode, an anode of electrolytic iron, and an E.M.F. of about 0·4 volt) is silvery-white and sometimes distinctly crystalline. It dissolves very slowly in warm dilute sulphuric acid and rusts in moist air. Occasionally specimens are obtained which are hardly attacked by acids or haloids. Type A iron is always very hard (it usually scratches glass) and brittle, but it loses these qualities when heated to redness. When the iron is exposed to air it slowly loses hydrogen, or more rapidly when it is immersed in hot water; this loss of hydrogen does not diminish its hardness and brittleness. The author takes the view that electrolytic iron of type A is $\gamma$-iron; it is, therefore, in unstable equilibrium at the ordinary temperature. When heated, it changes into the stable $\alpha$-iron, which is soft. It cannot be hardened by heating and sudden cooling, owing to the high temperature at which $\gamma$-iron changes into the $\beta$ form in pure iron. The presence of large quantities of hydrogen is attributed to the greater solvent action of $\gamma$-iron, which is known to dissolve carbon much more readily than $\alpha$-iron.

**Electricity in Mills.**—This subject has come in for a good deal of discussion in the provinces of late, and it may be hoped that the attention which it is receiving from technical men will prove to be the precursor of its early adoption by millowners on a large scale. The Dundee Institute of Engineers considered the question at their last week's meeting, when Mr. H. Richardson, the borough electrical engineer, while not advocating electric driving under all conditions, specifically combated the following objections to same: (1) that it is in its experimental stage, and therefore its extensive use in mills is not justified; (2) that the cost of repairs to electrical plant is higher than in the case of mechanical energy; (3) that the efficiency of electrical driving is lower than mechanical driving; and (4) that electric driving could not possibly make better and steadier running than the best mechanical driving, and that it is

Digitized by Google

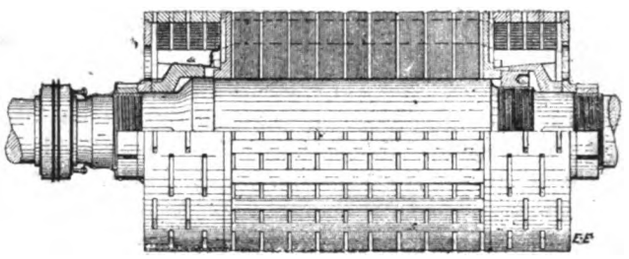
only advantageous in special cases. In support of this, Mr. Richardson quoted the case of the United States, where plant to the extent of some 20,000 h.p. has been installed for this purpose in cases where it would have been equally easy to instal the best mechanical driving. He proceeded to show that owing to the steadiness of speed, readier facilities for the observation of efficiency, and the comparative absence of shafting, belting, and gearing, the balance of advantage rested with electric driving. After dealing with the local aspect of the question, Mr. Richardson referred to the additional benefits in regard to light, smoke, and cleanliness secured by electric driving, and concluded by gently rallying the Dundee millowners upon their ultra-cautiousness. The advocates of mechanical power made a great point of the admirable qualities of the mill engine, which was echoed by Mr. D. J. Macdonald, the chairman, in his summing up; but they refrained from dealing with the inefficiency of the connecting gear between the engine and the mill plant. It is gratifyng to see that some of the millowners appear disposed to give electric driving a trial.

**Resistance Leads for Single-Phase Motors.**—The *Electrical World* of New York describes a patent just obtained in the United States by Mr. B. G. Lamme, the object of which is to so proportion the resistance leads in connecting the armature windings to the commutator bars in alternating-current motors as to reduce to a minimum the sparking between the commutator cylinder and the brushes. The current which flows in the coil under the brush is composed of two elements—that due to the working current and that due to the transformer action of the alternating flux. The amount of the induced currents in the armature winding depends upon the E.M.F. set up in them by the field magnetisation, and upon the amount of resistance in the closed circuit introduced by the coils, leads to the commutator, and the brushes. The inventor states that for minimum loss in the leads the induced current should equal the working current of the motor. It is evident, therefore, that the best value for the resistance of the leads is such that the induced currents may be limited to one-half the value of the total current supplied to the armature from an external source, so as to cause the current induced in the leads to equal the working current passing through them. Another patent issued to Mr. Lamme at the same time relates to a method of locating the resistance leads so as to secure the maximum mechanical strength. In order to obtain this the resistance lead should have a comparatively large cross-sectional area, its resistance being



proportioned by adjusting its length. As shown in the accompanying illustration, the lead is placed in the bottom of the armature slot, and preferably in the slot that contains one side of the corresponding armature coil, and is folded upon itself a sufficient number of times to obtain the proper length for the desired resistance. If the resistance leads are folded upon themselves an even number of times, they become non-inductive.

**Rotor of Turbo-Generators.**—Considerable difficulty has been encountered in the construction of dynamos for direct connection to steam-turbines on account of the centrifugal forces due to the high speed, and of the excessive noise due to air resistance when attempt is made to secure ventilation. The *Electrical World* of New York describes a design just patented in the States by Messrs. B. A. Behrend and W. D. Pomery to secure a compact and rigid well-balanced construction with all parts well protected and firmly held in place and to obtain good ventilation of all heated parts. The core, which is of the slotted type, is built up of laminæ grouped in sections spaced from each other by separators. The accompanying illustration represents a revolving field magnet, the windings being connected in series, so as to produce, when excited by direct current, a north pole and a south pole diametrically opposite each other, giving a bipolar field.



The windings are retained in the slots by wedges of phosphor-bronze, and the external surfaces are finished so as to give a perfectly smooth exterior. The end connections of the windings are covered by cylindrical pieces of nickel-steel having great mechanical strength. These cores serve not only to protect the coils, but also to withstand the great centrifugal force exerted upon them. The coils are separated from each other by spaces for ventilation, and the cylindrical covers are provided with openings for the same purpose, the openings coinciding with the spaces between the coils, and additional openings which are provided in the retaining end plates. At the interior surface of the end connections are located wedge pieces, four of which comprise an expansible ring, one of which rings is used at each end of the rotor. Within the wedge pieces is placed a clamping ring which, when forced into position, causes the wedge pieces which seat against the end plates to press outwardly against the end connections and securely hold them in a fixed position. In the operation of the rotor there is a free circulation of air through the openings in the end covers, and between the projections of the wedge pieces and out through the spaces between the coils and through the openings in the cylindrical covers. Ventilation is further secured by air passing into and out of the spaces between the sections of laminæ.

**Telephony and Telegraphy in the States.**—We have been favoured with a report on the telephonic and telegraphic systems of the United States for the year 1902, prepared by Mr. W. M. Steuart on behalf of the Department of Commerce. As these statistics deal largely in millions, not to say billions, they require a considerable amount of digesting, but the following is the substance of them. Under the head of telephone service three systems are recognised—commercial systems, including all systems operated by individuals, firms, or corporations for revenue; mutual systems, including systems operated through mutual arrangement between the persons deriving benefit from the service, primarily for the benefit of the owners; and independent farmer or rural lines having no regular exchange or central office. The first of these was by far the most important, and during the year covered by the report had in operation nearly 94 per cent. of the total number of telephones, while the mutual systems had in operation a little less than 4 per cent., and the independent or rural lines but a little over 2 per cent. Taking the total population of the continental United States for the year, as estimated by the Bureau of Census, it is found that there

Digitized by Google

was an average of one telephone to every 33 inhabitants, though different States show remarkable fluctuations. The commercial systems embraced 4,779,571 miles of wires, with 2,371,044 subscribers; the mutual, 70,915 miles, with 89,316 subscribers; and the independent rural, 49,965 miles, with 55,747 subscribers. During the year 4,971,413,070 messages were exchanged on the commercial systems, and 99,141,483 on the mutual systems. The value at par of all the companies' stock is some £70,000,000. The total revenue of all the companies for the year was between £17,000,000 and £18,000,000; the operating expenses and fixed charges, except interest on bonds, aggregated to slightly under 12½ millions; and after allowing for interest on bonds, and paying dividends to the amount of nearly £3,000,000, there was a net surplus of £1,335,610. The Bell system owned 3,387,924 miles of line against 1,462,562 by the independent companies, and the subscribers numbered 1,222,327 and 956,039 respectively. The messages on the Bell lines totalled 3,074,530,060 against 1,996,024,493. In regard to telegraphy there are 1,318,350 miles of wire, and 91,655,287 messages were dispatched during the year, the revenue totalling over £8,000,000. Dividends to the amount of some £1,300,000 were paid, leaving a net surplus of about £800,000. The outstanding stock represents £24,000,000. Besides this, the railways owned 884,349 miles of wire. It will be seen that the telephone systems own between three and four times as many miles of line as the telegraph systems, but a glance at some statistics for 1880 contained in the report demonstrates the enormous growth of both industries in the States.

**Fog.**—The city engineer and surveyor of Westminster, Mr. J. W. Bradley, has made a special study of the dispersal of fog, and last week at the Caxton Hall he lectured on the subject to the Westminster Debating Society, several members of the Westminster City Council being present. The causes which give rise to fog in varying circumstances of temperature, wind, and situation, were first of all dealt with, and the different types of fog were considered under three heads—steaming water fogs, cold surface fogs, and cloud fogs. Special reference was also made to the smoke fog or dust cloud which occasionally rises in the Metropolis. Mr. Bradley observed that, while the higher districts of the Metropolis usually enjoyed comparative immunity from fog, this was not always the case, as low-lying districts such as Rushey Green and Hammersmith also show marked freedom from fog, while over the higher part of Regent's Park it is by no means infrequent. Having alluded to the good work done by the Coal Smoke Abatement Society under the presidency of Sir William Richmond, Mr. Bradley referred to the Hon. R. Russell's estimate of £5,000,000 as the annual loss sustained by the people of London through smoke and smoky fogs. Particulars were given of the dispersion of fog by wind, and it was stated that when the velocity of prevailing wind reached 13 miles per hour, all fogs except very smoky fogs are dissipated, and that these require a velocity of about 30 per cent. greater. The dispersion of fog by electricity was then fully described, reference being made to the work of Sir Oliver Lodge in this direction. A demonstration was given of the dispersion of smoke produced by the burning of magnesium ribbon and its precipitation by an electric discharge. It was stated that the cost of fitting up the electrical method of dispersion in Piccadilly-circus, Trafalgar-square, Victoria Station, Hyde Park-corner, together with a few other centres, would probably be from £5,000 to £6,000, while the Strand or Victoria-street could be dealt with at about half that cost. A description was given of the method adopted by the Westminster City Council to light central spaces in time of fog by means of portable compressed-air oil lamps, and of their experiments with orange-tinted globes and special carbons in the electric arc lamps for the purpose of gaining a greater penetrative effect through the fog. Mr. Bradley further stated that, apart from the heavy indirect loss through fogs, there was a direct loss of some £200 per day in extra lighting, so that from the point of view of the central-station engineer fogs are not an unmixed evil. The welfare of the whole community, however, is a still more important consideration, and Mr. Bradley, in conclusion, made the interesting announcement that he and several engineers of the electrical supply companies in Westminster had accepted Sir Oliver Lodge's invitation to view his electrical installation for fog dispersion at Birmingham.

**Traction Progress in 1904.**—An interesting survey of the year's progress in the various fields of engineering is contained in the *Scientific American*. Coming to the electrical section, the author deals with the application of electric traction to trunk lines, not merely for their suburban service, but for long-distance travel between widely-separated centres. Pioneer work on an ambitious scale has, as our readers are aware, been begun by the New York Central, the most interesting feature of their scheme being that the express service will be operated electrically for a distance of 40 miles out of New York. This experiment is naturally fraught with the greatest interest, as so much depends upon the result. Reference is made to the competitive trials now being carried out in Germany between steam and electric traction over the Berlin-Zossen stretch of road, on which a speed of 131 miles an hour was reached by an electric car in 1903. Several high-speed express locomotives of special design are being tested, but up to the present time there have been no grounds for believing that for hauling heavy trains at speeds of 80 to 100 miles an hour the steam locomotive can compare with electric traction. On the other hand, the results already obtained during the experimental runs of the New York Central electrical locomotive on a six-mile stretch of their track near Schenectady (an account of which we published a few weeks ago) are very satisfactory. The data thus far secured prove that this electrical locomotive has all the powers of rapid acceleration, which is one of the best features of this form of traction. Its total weight is 95 tons, its maximum horse-power 3,000, and the maximum drawbar pull is 32,000lb. Already in the course of the tests a speed of 63 miles per hour has been reached with an eight-car train, and 72 miles per hour with a four-car train; and in the starting test a speed of 30 miles per hour has been reached in 60 seconds with an eight-car train weighing with the locomotive 431 tons, which is an acceleration of one-half mile per hour per second. With a four-car train weighing with locomotive 265 tons, the acceleration was at the rate of 0·8 of a mile per hour per second. This engine weighs 95 tons, and there is a possibility of its developing a maximum horse-power as high as 3·500. The author considers it would be quite feasible to build a locomotive for high-speed service, of 5,000 h.p. and 125 tons weight, that would not overtax the track and bridges, although if the New York Central venture leads to the general electrification of the trunk road for long distances, it is probable that the Sprague system of multiple control will be preferred. Meanwhile the trolley road systems throughout the country are gradually approaching the steam railroads in the solidity of their tracks, the size of their rolling stock, and the general comfort of travel. Already on interurban roads the electric sleeping-car and the electric dining-car have made their appearance, and are giving satisfaction.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 152.)*

### MULTIPLEX MULTIPLE-CIRCUIT WINDINGS.

**Double Windings Doubly Re-entrant.**

In Fig. 10 we have re-drawn Fig. 1, having added a second winding exactly similar to the first, but spaced in such a way that its spirals occur exactly half-way between the spirals of the first winding (the piece of the first winding included between the lines A and B being called, as before, one spiral). This winding is to the simple winding of Fig. 1 exactly what a double-threaded screw is to a single-threaded screw. Such an arrangement is called *a double (or duplex) multiple-circuit* ring winding, and since each winding is entirely independent of the other, each closing upon itself, it is said to be *doubly re-entrant.* It will be noticed that when the second winding is connected down to the commutator in the same way as the first winding, its segments naturally occur alternately interspaced with those of the first winding, hence the commutator belonging to this form will have twice as many segments as the corresponding armature with a single winding.

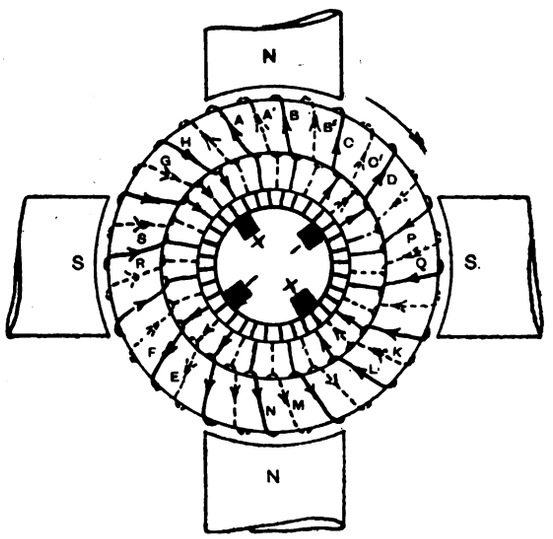

FIG. 10.

Now, if each brush bearing upon the commutator be made so wide that it never touches less than two sections, we find that we have, with respect to these brushes, the two windings on the armature continually in parallel.

For imagine for a moment that the two windings were moved toward one another until such a spiral as A coincided with $A^1$, then it is obvious that (if the wire with which A and $A^1$ are wound is the same as was used in Fig. 1) we have simply wound the armature of Fig. 1 with two wires in parallel, but have connected the winding to double as many commutator sections.

**Object of a Double Winding.**

Thus the sole object of a double, or duplex, winding is to enable the armature to carry more current, and to split up this heavier current into sufficiently small parts while it is being commuted.

This matter is made more clear when in Fig. 10 we note that between the two upper brushes there are *in series* the spirals marked A, B, and C, and also as a separate series the spirals $A^1$, $B^1$, and $C^1$. Now A, B, and C are *not* in series with $A^1$, $B^1$, $C^1$, but *in parallel* with them, therefore (considering the upper part of the winding alone), between these two upper brushes we have the sum of the electromotive forces due to three spirals, but the current is due to two sets of three spirals.

Thus has a double winding no advantage over a single winding of twice the section except so far as it enables a heavy current to be commuted satisfactorily; and we should never use a double winding until we had reached (without satisfactory commutation), the maximum possible number of segments with a single winding—*i.e.*, one segment per spiral. This point is further discussed at the end of this section.

**Comparison of Duplex and Simplex Windings.**

To sum up, we might compare Figs. 10 and 1 as follows: Supposing each winding in Fig. 10 to be exactly similar to the winding in Fig. 1, the two armatures when revolving at the same speed and in the same field will give exactly the same voltage and will have the same number of brushes.

Fig. 10 will give, without dangerous heating, practically twice the current of Fig. 1, because it has a second set of circuits on its armature placed in parallel with the original set. Fig. 10 will have a commutator with twice as many segments as Fig. 1, and the peripheral length of brush will be arranged so that it covers at least 1½ segments. But it must, of course, be remembered that in practice a ring armature is not wound as Fig. 1, but with the spirals packed close together; therefore, as a rule, to any simplex winding we cannot add another, making it duplex, without some special provision, such as boring out the air-gap. If we use the same core first for a simplex winding and then for a duplex winding, we should probably have in each case the same number of spirals upon the armature and the same number of commutator sections, if we assume one section per spiral. But the duplex winding will have between each pair of brushes half the number of spirals in series that the simplex winding has, while in the simplex winding the spirals between any pair of brushes are all in series as compared with the duplex winding, which will have them divided into two sets in parallel. So that for a given core, with a given speed and a given field, we can obtain a certain output. If we wind the armature simplex, this output is A amperes at V volts; while with a duplex winding it will be 2 A amperes at $\frac{V}{2}$ volts, with the same number of commutator sections. If, on the other hand, we wind it with two wires in parallel and simplex (or one wire of twice the section), we shall obtain 2 A amperes at $\frac{V}{2}$ volts, but with half the number of commutator sections.

A double winding, then, in general only supplies a method whereby we are enabled to change the output of a machine by simply altering the pitch of the winding, without changing either the number of turns upon the armature or the number of commutator sections. But should there chance to be on any machine room for adding more turns, then we might have such a contrast as that existing between Figs. 10 and 1, where we see that though in Fig. 10 there are twice as many spirals upon the armature as in Fig. 1, and though the former gives twice as much current as the latter, yet the number of commutator segments is increased in proportion to the number of spirals, so that the current commuted per segment remains the same. This, as has been said, is the real advantage of this type of

Digitized by Google

winding—viz., that it enables the machine to give a larger current without commutation difficulties.

**Multiplex Ring Windings in General.**

To return to Fig. 10, we might have placed two windings or three, or any number for which there was room, each exactly similar to that in Fig. 1, between the spirals of the simplex winding. In the illustration we have placed only one extra, and the armature is double wound, doubly re-entrant. Had we placed two extra, it would have been triply wound (or triplex), triply re-entrant, and so on. A very convenient notation has been introduced to express this. If an armature is single wound, it is denoted by o; if double wound, doubly re-entrant, by o o, to show that there are two absolutely independent windings. Hence the full description of Fig. 1 is—

four-pole multiple-circuit ring, 16 spirals, o.

That of Fig. 10 is—

four-pole multiple-circuit ring, 32 spirals, o o.

That of Fig. 8 is—

six-pole multiple-circuit drum, 24 inductors, o.

**Multiplex Drum Windings.**

Now, as from Fig. 6 Figs. 7 and 8 were derived, giving drum windings exactly analogous to

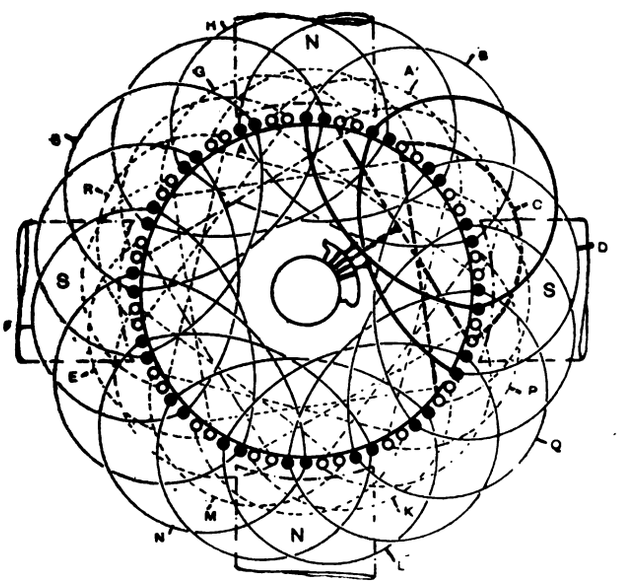

Fig. 11.

the original ring winding, so from Fig. 10 by the same process we may develop a *double-wound* drum. The two windings on the drum will be entirely separate, just as with the ring, and the commutator segments will be similarly interleaved. Fig. 11 shows the drum counterpart of Fig. 10. The connections belonging to the second winding are drawn dotted, and a close study of this figure will show all that is to be learnt about these doubly-wound doubly re-entrant drum windings.

The diagram is likely to appear at first sight confusing, but the scheme of each winding has, as far as possible, been kept separate by the use of heavy black dots to represent the inductors of one winding, while circles represent those of the other. To the same end a single turn of each winding has been accentuated, and the commutator has been omitted except for three segments, which just serve to show how the parts belonging to one winding are interleaved with those of the other winding, exactly as in Fig. 10.

**Rules for Multiplex Drum Windings of Multiple Re-entrancy.**

Now, since for a single drum winding the total number of inductors must be divisible by 2, it follows that, when two such windings are placed upon the same armature, the total number of inductors must be divisible by 4; or if three such windings are used it will be divisible by 6, and so on, *no matter what the number of poles.* Each time that a new winding is added, a new set of commutator segments must be allowed for; and since the only object of adding a winding is to increase the current capacity of the machine without risk of sparking, it follows that all the windings must be in parallel to be effective, and consequently at each collecting point the brush must be wide enough to touch a number of segments at least equal to the number of windings upon the armature. The number of poles determines the number of collecting points *only*, and there is no difference in the behaviour of the multiple-circuit ring and the multiple-circuit drum except this—that whereas in a ring winding all *return* connections pass within the armature (out of the active field), the return connections in the drum pass under a pole of different sign. Thus the same ring armature may be placed in a two, four, six, or eight pole field with a corresponding number of brushes, and work satisfactorily in each; but a drum winding, if arranged for a four-pole field, would not act well in an eight-pole field, because the return inductors would lie under a pole of the wrong sign. This is best seen by drawing out a simple four-pole drum winding and then sketching eight poles around it.

Though perhaps it is better in the case of double and triple windings of this sort to consider them as so many *separate* windings, yet we might develop a set of rules to apply to such windings similar to those for the simple windings given above. If in Fig. 11 we number all the inductors consecutively, we find that the following rules will hold; they are developed from previous reasoning:

(1) The number of spirals on the armature must be a multiple of the number of independent windings—*i.e.*, in the case of a drum winding the number of inductors must be divisible by *twice the number* of independent windings.

(2) For connecting a drum, number all the inductors belonging to one winding, and consider it as alone upon the armature. Then connect according to the rules given above for simple windings.

We have already laid stress upon the point that for a simple or simplex multiple-circuit drum winding, starting from inductor No. 1, the second end connection brings us naturally to inductor No. 3. By the same reasoning, in a double or duplex multiple-circuit winding the second end connection must bring us to inductor No. 5. Similarly the second end connection of a triple or triplex multiple-circuit winding will bring us to inductor No. 7, and so on.

From this it follows that whereas in a simplex multiple-circuit drum winding the difference in the number-pitches $y_1$ and $y_2$ is 2, in a duplex multiple-circuit drum winding it will be 4, in a triplex 6, etc. So that $y_1 - y_2$ depends upon the number of windings, and becomes $= 2\,m$, where $m$ is the number of windings.

Thus we may write Rule 2 as follows:

(2A) Number all the inductors. Take as a forward number-pitch an odd number approximately equal to, or slightly greater than, $\frac{w}{p}$; call this pitch $y_1$, then the backward pitch becomes obviously $(y_1 - 2\,m)$, where $m$ is the number of independent windings.

## THE LOTS ROAD POWER STATION.

(*Continued from page 155.*)

In our last issue we carried the description of the above station down to the point at which the current generated by the turbo-alternators is dealt with by the switchboard for distribution to the various sub-stations. This switchgear, which was designed and supplied by the British Thomson-Houston Company, of Rugby, we now propose to describe more in detail, using photographs and drawings kindly lent us by that firm. The design of suitable switchgear to properly handle 50,000 kw. at 11,000 volts constituted one of the most difficult problems in the development of this great station, owing to the dependence of reliable operation upon the switchgear, the impossibility of making experiments on anything like full power, and the lack of precedent in the United Kingdom. Such precedent as there was existed only in one or two large steam-power stations in New York City. In its main features the gear of the Chelsea station follows the general lines of these stations, which approach it in power and voltage.

A brief history of the development of switchgear for handling with ease the output of large stations at high voltage may be of interest. The chief detail of such gear is the power-actuated oil-break switch. Previous to the construction of the large New York stations, a number of power-actuated oil-break switches of rather primitive form had been in experimental use in several large stations using high-voltage transmission. One form for these switches consisted essentially of wooden barrels filled with oil in which a crude form of knife-switch was immersed, all connections and operating gear being taken out through the top of the oil. The relatively good behaviour of these first types under emergency conditions proved that for large powers the air-break switch was not worth consideration. These primitive switches were then redesigned to the various forms considered the most satisfactory at the present day.

In the form which has been used in the station here described, the large oil-barrels have been replaced by metal oil-pots, the bases of which form the live contacts. The moving part of this switch consists of an inverted "U" shaped rod, the two ends of which dip centrally into two oil-pots. The oil-pots themselves are electrically connected to the incoming and outgoing cable of one phase respectively. When the U-shaped rod is forced down into contacts in the bases of the oil-pots, the circuit is closed. When the U-shaped rod is pulled up out of the contacts through the oil, the circuit is broken. Insulating stuffing boxes at the top of the oil-pots prevent the oil from being thrown out in case the disruption of the circuit raises a high pressure within the oil-pot. The advantage of this construction over the previous form lies in the fact that a much smaller amount of oil is used, and this oil is enclosed in a series of metal vessels, and is, therefore, less likely to spread a serious fire if ignited at any point. Absolutely all of this oil is above the points where the circuit is broken, and is therefore available to drown out the arc.

In their original form the switches were actuated by compressed-air cylinders, the valves of which were electrically controlled. Pneumatic control has since been superseded by direct electric control, usually by means of a small direct-current motor mounted on each complete three-phase switch. The switches used in the Lots-road station of the London Underground Railways Company, Limited, follow this precedent, and also resemble their predecessors in the distribution of the extra high-tension parts over a large area, the remote control feature allowing the scattered oil switches to be operated from one central keyboard. The high-tension oil switches, of which there are about 100 complete three-phase sets, are scattered with the corresponding 'bus bars, cables, etc., over three switchboard galleries running the whole length of the station, about 450ft. on the Lots-road side—*i.e.*, the side of the turbine-room, away from the river and boiler-room (Fig. 4).

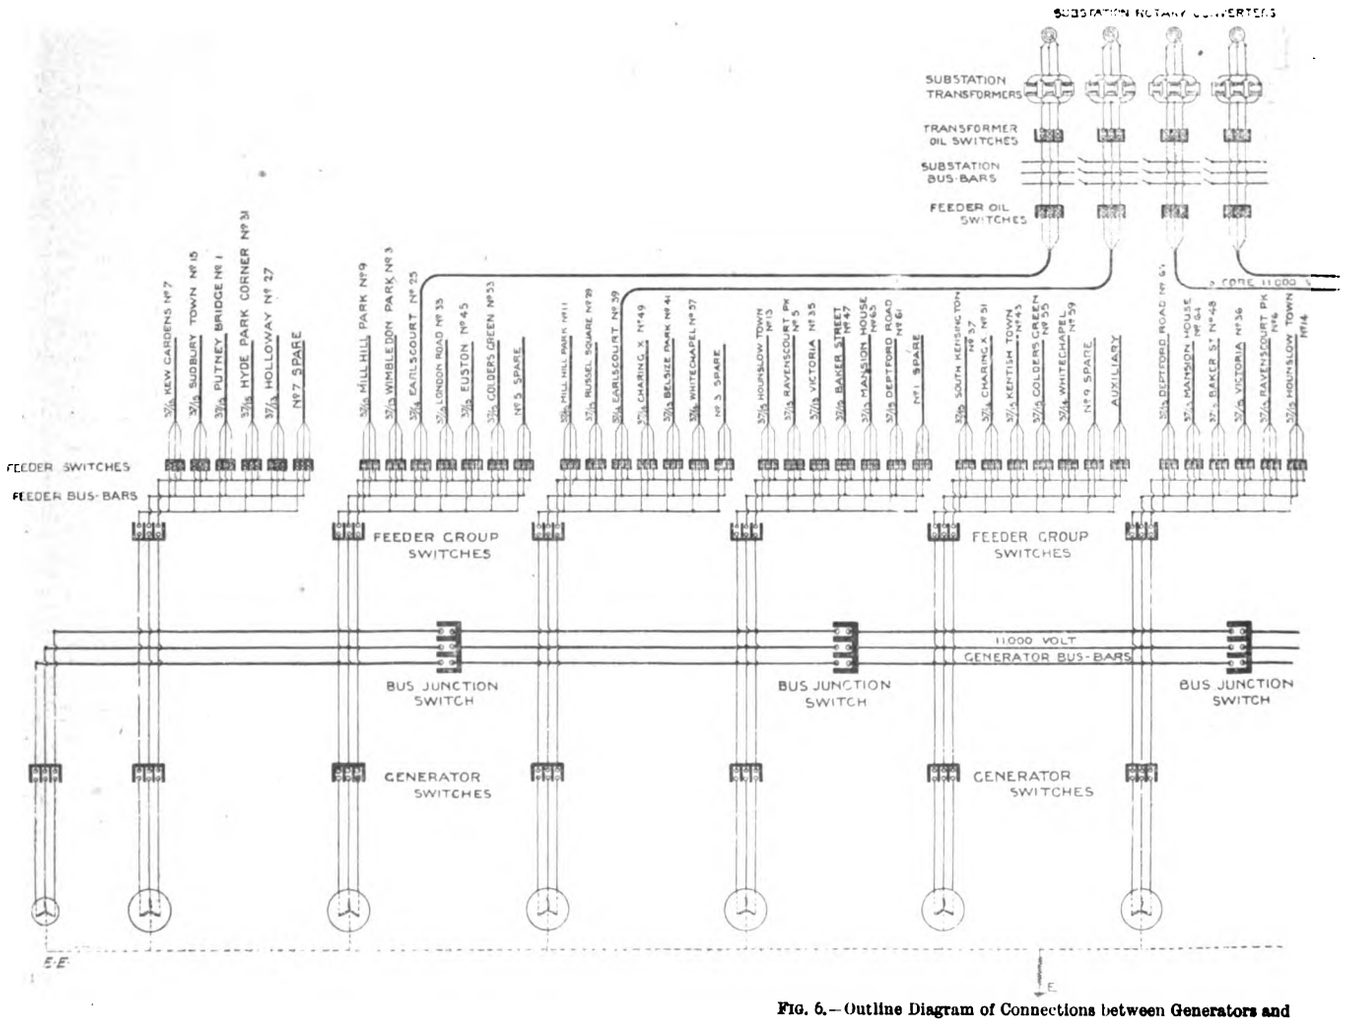

FIG. 6.—Outline Diagram of Connections between Generators and

In general the arrangement is such as to make the extra high-tension leads as direct as possible. For example, the several generator switches are not grouped together, but

Digitized by Google

are located nearly opposite their respective generators. The oil switches supplying the outgoing lines are also

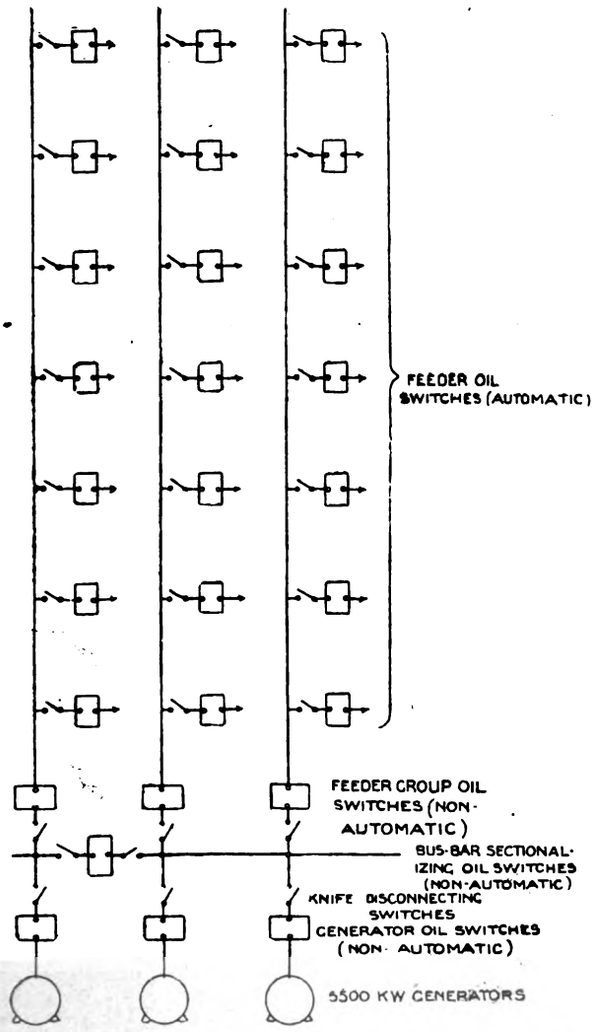

FIG. 7.—Diagram showing Typical Connections for Group and Feeder Switching at Lots Road.

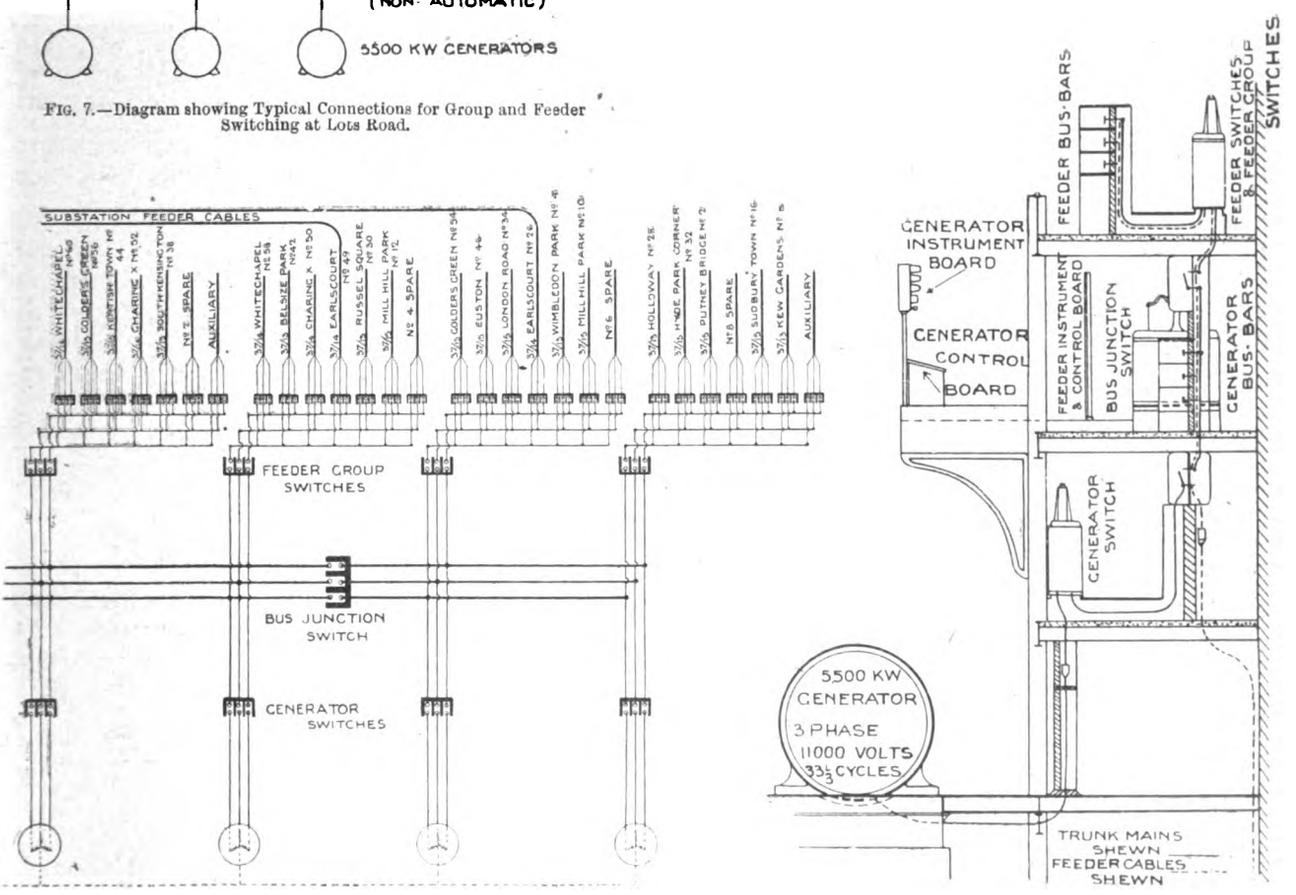

Sub-Stations on the Underground Electric Railway Company's System.

scattered the whole length of the house, and are supplied from the main 'bus bars between the several generator switches. Thus there is no single 'bus carrying the whole station output. The extra high-tension 'bus bars are not in duplicate, owing to the complications which a duplicate arrangement involves in extra high-tension work, with its isolating barriers, and also owing to the complications in operations which might arise if, for example, the duplicate 'bus bars should be unintentionally paralleled through two or more high-tension transmission lines running to the same sub-station.

To enable a fault even on the extra high-tension main 'bus to be cleared without suspending service, and to make it possible to inspect, repair, or alter any part of the extra high-tension main 'bus, this is divided into five sections by means of four oil switches, as indicated in the accompanying general diagrammatic sketch of connections (Fig. 6). To each of the five sections are connected two of the 5,500-kw. main generators, each of which is provided with one complete motor-operated three-phase oil switch. From each of the five main sections of the 'bus bar, about 13 of the total number of 68 three-phase cables leading to the sub-stations are supplied. Each of the outgoing cables is provided with its own complete motor-operated oil switch, but the connection is not made directly from this feeder switch, as it is called, to the main 'bus. From each of the five sections of the main 'bus power is delivered through two "feeder group" or "group" oil switches, each such switch feeding a short length of 'bus bar, termed a "group 'bus," from which in turn six or seven feeders are supplied through their respective oil switches. This principle of grouping the feeders was adopted with the object of getting two oil switches in series with each other, so that in case of the failure of one from any cause, the other would be available to open the circuit in case of an emergency. Obviously two complete motor-operated oil switches for each of 60 or 80 feeders would add so greatly to the number of parts and general complication that the duplication would be of doubtful advantage. A compromise was obtained by putting a single oil switch in each feeder, with a group switch for each six or eight. Each sub-station is provided with two or more separate extra high-tension feeders, each consisting of a three-core cable. These feeders supply one high-tension 'bus bar in the sub-station. The several feeders to one sub-station are taken from different

Digitized by Google

sections of the extra high-tension 'bus bar in the generating stations, so that all sub-stations can be supplied through part of their feeders, even with one complete section of the main 'bus bar in the generating station out of service.

### The Oil-Break Switches.

Each oil switch is enclosed in a fireproof brick and stone cellular compartment (Fig. 8), designed to prevent the spread of a burn-out in case the oil switch should for any reason fail. This principle is also carried further by isolating each phase in its own cell with masonry barriers between the cells, the idea being that if one phase should fail the other two would open the three-phase circuit if the spread of the trouble to them is prevented. The general construction of the switch is shown in the accompanying illustrations (Figs. 8 and 9). The contact rods within the oil are capable of carrying about 300 amperes continuously. This is ample for any one of the outgoing feeders in this station, but is not equal to the load which may come upon any one of the 'bus-bar section or group switches. For these cases an auxiliary contact in air is made across the tops of the oil-pots, this contact being broken before the contact within the oil-pot. These air contacts can be seen in the front view of one of the 'bus-bar section switches (Fig. 9). The moving parts of the switch are thrown from the "off" to the "on" position or from the "on" to the "off" position by means of powerful coil springs contained within the mechanism above the stone slab which forms a cover to the extra high-tension parts. When thrown by one spring against the other, they are caught and prevented from rebounding by means of a clutch through which the driving motor immediately takes hold and supplies the necessary power to complete the compression of the receiving spring. In other words, the moving parts are tossed from one spring to the other, the motor simply serving to make up the losses and complete the stroke. The first throw of either spring is ample to close the switch from the open position, or open the switch wide from the closed position. This feature of throwing the somewhat heavy moving parts from one spring to another gives quick action without violent jars, as one spring cushions the throw of the other.

Each oil switch is connected to the 'bus bars through three knife-blade isolating or disconnecting switches, which are not intended to be opened when carrying current, but can be readily opened when the circuit has first been broken by means of the oil switch. These knife switches are operated by means of long wooden rods with hooked ends, which may be engaged in holes through the knife blades.

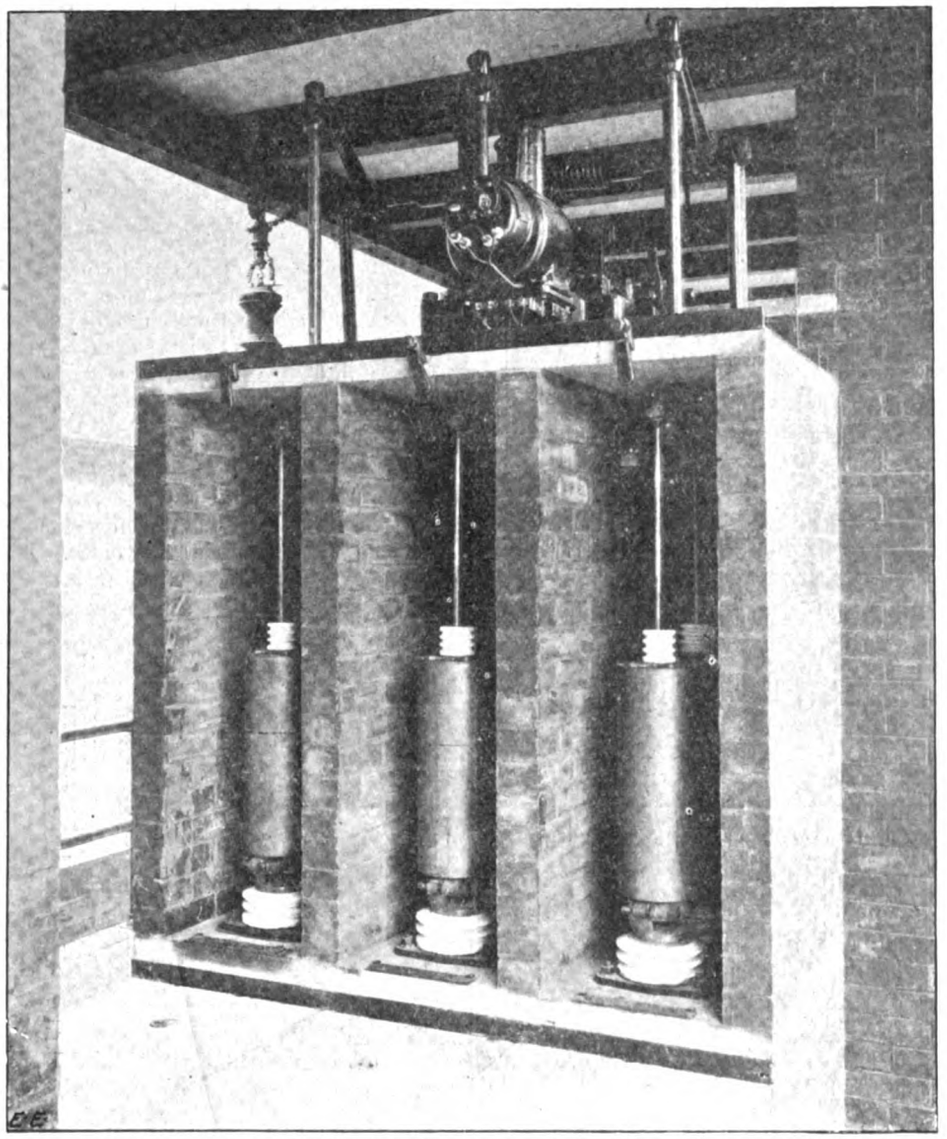

Fig. 8.—Typical B.T.H. Oil Switch with Subsidiary Air Contacts, as used at Lots Road.

These isolating switches serve to disconnect the live parts of the main oil switch from the 'bus bars for inspection, cleaning, etc, and also make it possible to test the mechanism of any oil switch without connecting the corresponding machine or feeder to the live bars. The knife disconnecting switches, together with all other high-tension gear such as main 'bus bars, pilot transformers, main leads, etc., are thoroughly isolated by means of masonry barriers either of brick or artificial stone construction.

### The Switchboard.

The extra high-tension operating and instrument boards are of two types, one made up of the usual vertical panels, the other consisting of an inclined bench-board, or table (Fig. 10), on which are mounted the handles of the control gear, and an instrument section separated from the bench-board by a space through which the operator can

Digitized by Google

glance over the station. This bench-board stands in a projecting bay of the second gallery with the vertical panels immediately behind it, so that the operator has the switchboard both before him and behind him, thus greatly shortening the total length of travel required to control all of the gear. All of the machines are controlled and measured on the inclined bench-board facing the station and on the corresponding instrument panels, while all of the outgoing feeders are handled on the vertical panels (Fig. 11); thus, when the operator faces the station he has the control of his machines in front of him and of his feeders behind him. Through the open space between the bench-board and the instrument panels above it the operator can look out over the station.

pole type, is, however, mounted directly on the generator panel in the controlling bench-board. Each generator panel is therefore equipped with: (1) one controlling hand switch for main oil switch; (2) two indicating lamps to show whether the main oil switch is in open or closed position; (3) one field discharge switch; (4) one field rheostat motor controller; (5) one synchronising receptacle; (6) one signal push switch to turbine position; (7) one controlling switch for turbine governor motor. By means of the last device the speed of the turbine may be adjusted in order to bring it into synchronism with the other machines; also when the machines are in parallel the division of the load may be adjusted from the switchboard.

For each generator there are also the following instru-

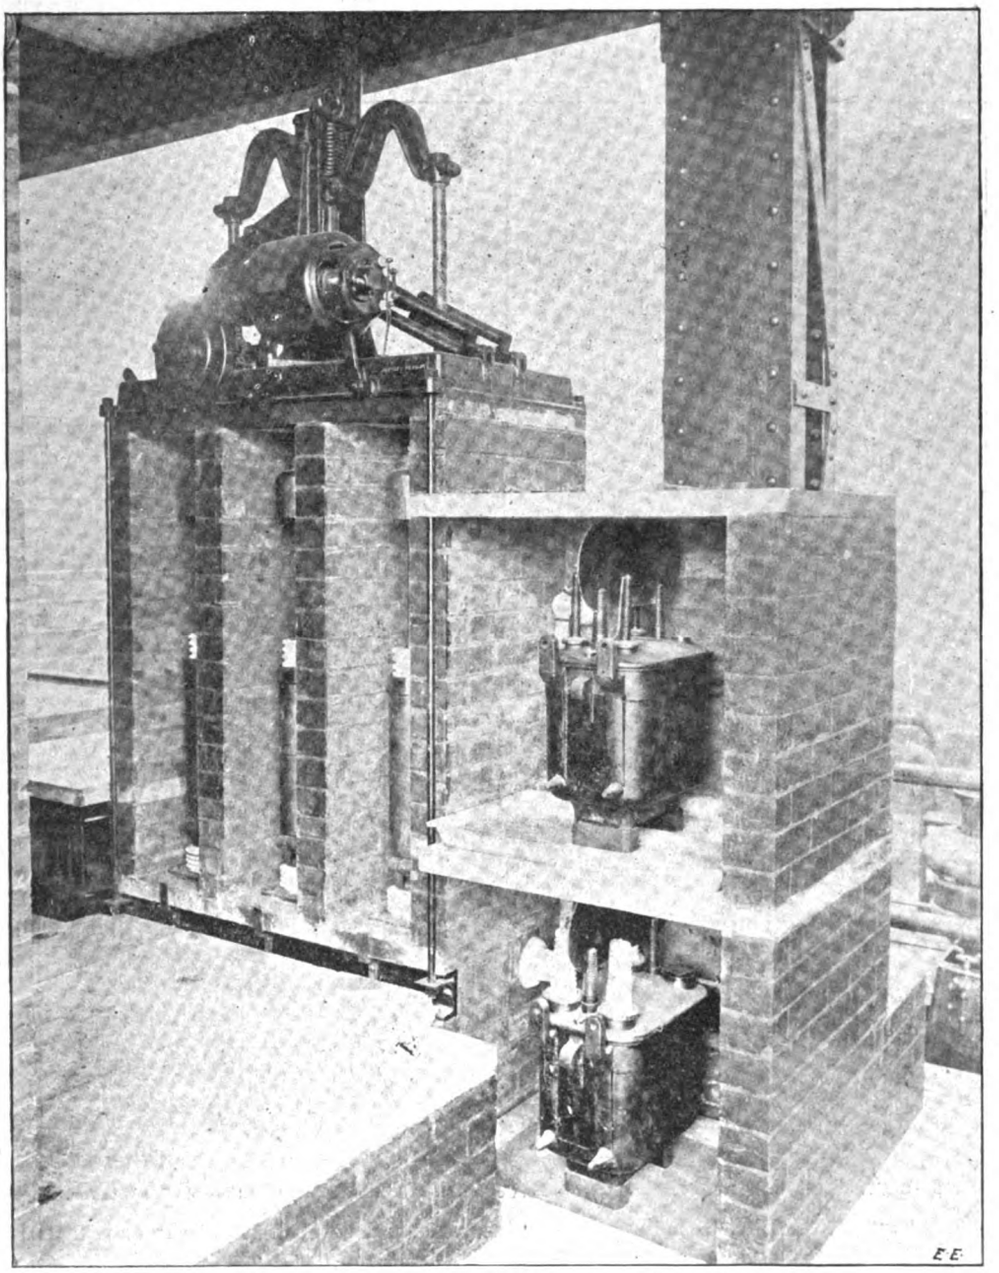

FIG. 9.—View of Motor-Operated Oil Switch and Potential Transformers.

On account of the large size of the field rheostats necessary to handle the excitation of these large machines, and particularly on account of the high temperature at which these rheostats would run run if crowded together, it has been necessary to locate them at some distance from the operating board, for which reason their contact arms are motor driven. A small controller on the bench-board panel for each generator serves to start, stop, or reverse the direct-current motor driving the corresponding field rheostat. Limit stops on the rheostat dial also serve to cut off the current of the motor in case the operator attempts to run the contact arm beyond the limits of the dial. These motor-operated rheostats are placed above the auxiliary switch-board. The main field discharge switch, which is of the single-

ments: three main ammeters, one main voltmeter permanently connected across one phase by means of a potential transformer, one power factor indicator, one field ammeter, one integrating watt-hour meter. The latter is of the single-phase type, with a potential derivation of proper phase relation to give correct readings on one phase of the three-phase circuit. On account of the fact that the load on this system will be almost entirely of a perfectly balanced character, the complications of polyphase watt-hour meters designed to read properly on unbalanced circuits are not considered warranted. Each generator is also equipped with one reverse-current relay designed to light up an alarm lamp, but not to operate the corresponding oil switch automatically. The object of this device is to give

Digitized by Google

the switchboard attendant instant notice on the proper panel if any generator fails. Automatic operation of the generator switches is avoided owing to the liability of excessive out-of-phase oscillating cross currents when a heavy fault occurs outside on the network. These momentary rushes of cross current would pull out the generators if equipped with reverse-current automatic release, and suspend the service, a result which is to be avoided on this system except in the very last extremity.

The highest voltage on the switchboard or bench-board is the 125 volts of the exciter and switch operating circuits. All alternating potentials for voltmeters, wattmeters, synchronising, etc, are derived from potential transformers having a ratio of 100 to 1, thus giving 110 volts when the line voltage is 11,000. One terminal of the secondary circuit of each of these potential transformers is earthed on a ground 'bus bar, which circulates through the extra high-tension gear for the purpose. Thus, if a high-potential instrument transformer should by any chance break down between the primary and secondary coils, the breakdown current would be carried off to earth without raising the potential of the secondary circuits supplied from the transformer. Similarly all ammeters, overload relay coils, series coils of wattmeters, etc., are supplied from series or current transformers giving a secondary current at full load of $3\frac{1}{2}$ amperes at a pressure of, roughly, 10 to 12 volts. The secondary circuits of these current transformers are earthed similarly to those of the potential transformers above mentioned. The current transformers are substantially designed with a jointless magnetic circuit requiring negligible magnetising current, thus giving them a very accurate and uniform ratio of secondary to primary amperes throughout their whole load. They are also of ample power to furnish current for either one indicating instrument alone, or two indicating instruments in series with an integrating instrument and relay, without appreciable change of ratio. Thus any 40 to 1 current transformer is interchangeable with any other 40 to 1 current transformer, regardless of the number of instruments for which it furnishes current within the limits reached in this station, and without recalibration of said instruments.

The current and potential transformers are, of course, conveniently located to the extra high-tension leads to which they are connected. To connect these transformers and the oil switches with the central switchboard, a large number of small leads are required. These are all run in extra heavy screwed Simplex pipe, largely of the $1\frac{1}{2}$in. size. These pipes were laid on top of the gallery floor joists before the flat concrete arch floors were put down. Thus the pipes have been buried out of reach of trouble in the concrete. The piping system was very thoroughly worked out to carry each particular pipe as close as possible to the individual device, such as current or potential transformer at one end and the corresponding controlling switch, relay, or instrument which it should reach at the other end. This was done entirely without main cross-over boxes into which it is sometimes customary to bring a large number of pipes, and in which the wires can be generally crossed over to avoid the labour of laying out each pipe accurately from start to finish. The pipes themselves form a number of crosses in the concrete, due largely to the fact that, although a given sub-station is supplied from sections 1, 3, and 5, for example, the three controlling switches, ammeters, and integrating watt-hour meters for the feeders of this particular sub-station are grouped together on one panel at the feeder board. The iron-armoured tubing takes care of all of these crosses of controlling and instrument wiring without any danger of interference between circuits.

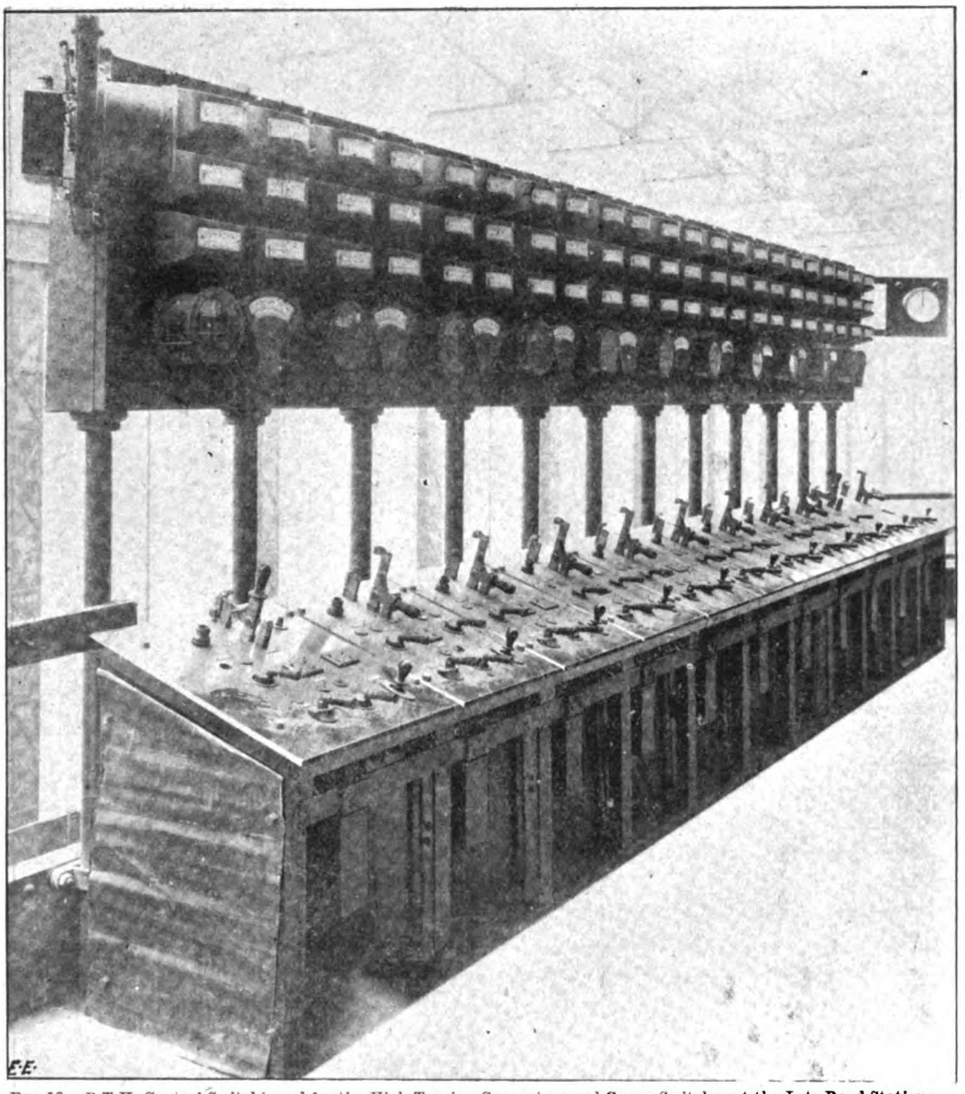

FIG. 10.—B.T.H. Control Switchboard for the High-Tension Generators and Group Switches at the Lots Road Station.

In answer to objections that have been raised to burying such iron-armoured tubing in the concrete, on the score

Digitized by Google

that it would be difficult or impossible to get at the wiring in case of severe burn-outs which might injure the pipe, it may be said that considerable experience with this form of construction has shown that burn-outs, when they do occur, do not injure the pipe, and that the burned-out wires can readily be drawn out and new wiring installed, even where the piping is entirely inaccessible. The use of extra high-tension enclosed glass tube fuses in the primary leads of the potential transformers prevents any considerable rush of power through them into the piping in case of a fault. The current transformers cannot, of course, be similarly protected, but the solid earth connection of one secondary terminal takes

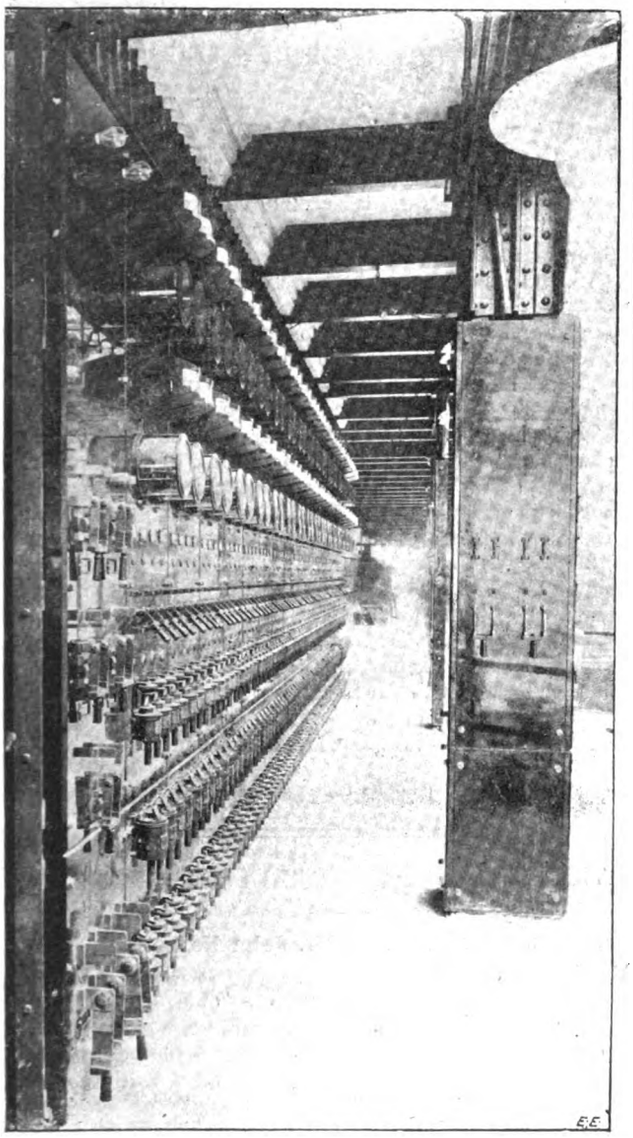

FIG. 11.—B.T.H. High-Tension Feeder Switchboard at Lots Road.

care of any possible transformer breakdown without injury to the piping system carrying the secondary conductors.

### THE AUTOMATIC PROTECTING DEVICES.

As noted above, the main generator oil switches are non-automatic and are closed and opened by hand control only. The 'bus-bar sectionalising switches and the group switches are similarly non-automatic. The individual feeder switches are the only automatic extra high-tension oil switches in the station. These are equipped with overload relays of the adjustable time-limit type, the time feature being obtained by an air dash-pot so designed as to allow the relay contacts to close instantly in case of a short-circuit, while a moderate overload will only close the contacts after an adjustable time limit of several seconds. To provide for operation with the neutral of the extra high-tension generators earthed, and to take care of all possible breakdown between any feeder conductor and the lead sheath, a relay is connected in each of the three phases of each outgoing line, the three relay contacts being connected in parallel to supply the motor of the corresponding oil switch, thus a breakdown to earth on any one of the three phases trips out the whole feeder at the generating station end. The relay contacts for all the feeders are supplied through what might be termed an alarm relay, which in turn rings a gong in case any extra high-tension switch trips out automatically, this alarm relay being inactive when the extra high-tension switches are opened by hand control. To enable the operator to readily find which one of his many feeders has tripped out automatically, the alarm relay also illuminates one of 10 alarm lamps, indicating to which group the faulty feeder is connected.

The oil switchgear is designed in accordance with the modern idea that the power to be broken by any one oil switch cannot be determined by the rating of the corresponding machine or line, but under emergencies may arise to the whole short-circuit output of the station. The idea is such an important one that a little further explanation may be warranted in spite of its obviousness. In the case of a fault upon an extra high-tension feeder which may be rated 2,000 kw. and may never normally carry more than that, the

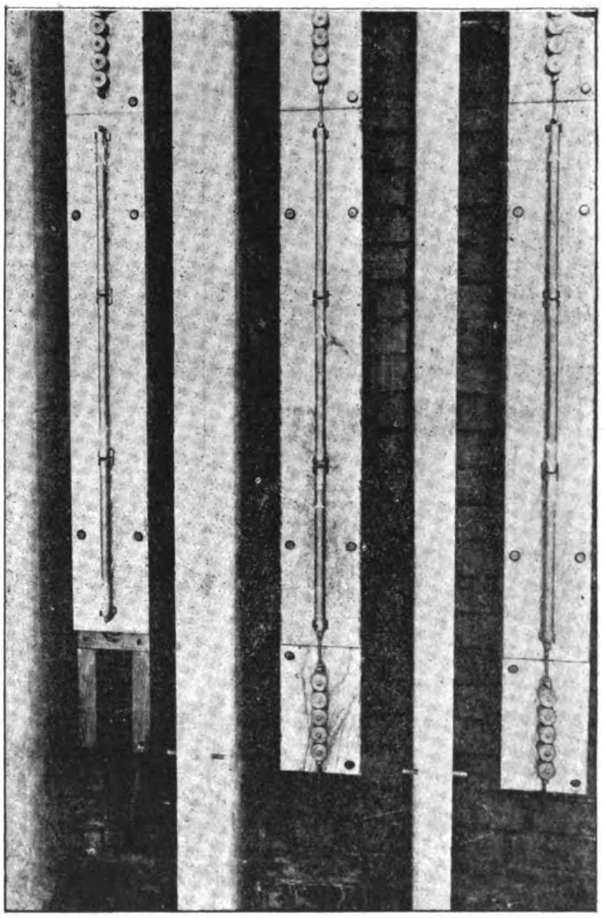

FIG. 12.—Static Discharges at the Chelsea Power Station.

power to be broken by the feeder oil switch will not be limited to 2,000 kw., but will be whatever the whole station can generate on short-circuit, together with considerable power that will be momentarily thrown back from all synchronous machinery on the system by virtue of its inertia and excitation. It is almost needless to say that the extra high-tension oil switches for this station have not been tested on a solid short-circuit of 50,000 kw. of machinery, but similar switches have broken faults on systems nearly as large without damage to the switchgear.

In accordance with modern practice no charging devices have been installed for gradually applying voltage to the extra high-tension three-core cables supplied from this station. It is argued that with oil-break switches no charging devices are necessary, as the harmful effects of throwing a cable directly into circuit are said to be due to the air arc which strikes across between the contacts of an air-break switch for a fraction of a second while the switch is approaching the closed position. These effects are not

Digitized by Google

found with an oil-break switch, which apparently does not allow the current to strike across its contacts until these are so close that the current persists without an intermittent make and break at each alternation. The connection of the neutral of the generators to earth is made through a resistance of six ohms, thus limiting the flow of current in case of a solid earth on any phase to about 1,000 amperes. This is ample to pull out the faulty feeder, but will not drop the synchronous machinery out of step as would a solid short-circuit.

### The Auxiliary Switchgear.

For handling the exciters and for supplying power to a large number of motor-driven auxiliaries scattered through the station, which aggregate approximately 100 motors, there is mounted in one gallery at one end of the station a switch-

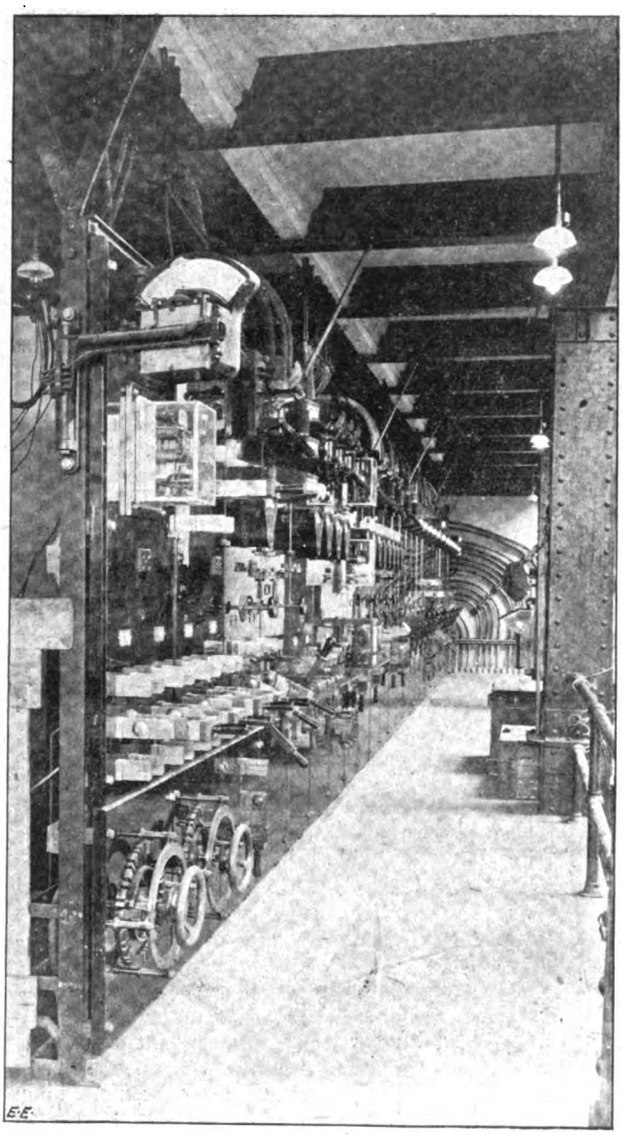

Fig. 13.—Auxiliary Plant Switchboard at Lots Road.

board (Fig. 13) as large as that of the average power-house and capable of handling fully as much power. The exciter system consists of four 125-kw. 125-volt compound-wound engine-driven generators, also of the British Thomson-Houston Company's make. To avoid any chance of short-circuiting across the exciter 'bus bars, the exciter panels are single-pole, the other polarity, together with the equaliser connections, being handled by switches mounted on pedestals adjacent to the exciters; thus only one polarity of the exciter system is carried to the exciter switchboard gallery.

For supplying the direct-current motor-driven oil switches, motor-driven field rheostats, and other switchgear, motors, and control circuits, two 125 volt storage batteries have been installed, the duplication being for the purpose of allowing one storage battery to be carrying the load while the other is charging. These batteries may be charged from a 125-kw. motor-generator set, taking power from the three-phase side. The motor of this set is of the synchronous type, and at the time of writing this machine is being used reversed, taking power from the direct-current side and generating power on the alternating-current side for extra high-potential tests. Suitable end-cell switches are provided to keep up the delivered voltage as the battery discharges. An emergency connection is also provided, so that the storage batteries may be charged from one or more of the exciters in case the synchronous motor-generator set becomes crippled. The auxiliary board also provides for supplying a number of direct-current crane motors from either the motor-generator set or in cases of emergency from the exciters. Like the extra high-tension 'bus, the exciter 'bus is sectionalised into two parts, so that continuous service can be given by the plant, and alterations can be made on either part of the 'bus at times of light load.

For the supply of the 80 odd induction motors driving air and circulating pumps, stokers, conveyors, etc., throughout the station, three banks of air-blast step-down transformers have been installed, each bank consisting of three 500-kw. transformers delivering 220 volts when supplied at 11,000. Two of these banks, aggregating 3,000 kw., will be required at times of heavy load, the third being a reserve. On the extra high-tension side these are supplied from three different sections of the main high-tension 'bus bars through the usual group switches and individual transformer bank switches, the controlling switches of the latter being mounted on the auxiliary board. On the low-tension side these three banks of transformers feed a 220-volt 'bus, which again is not in duplicate, but is sectioned into two parts, so arranged that one bank of transformers feeds each half of the 'bus, and the third bank can be connected to either or both. These low-tension connections are made by means of heavy air-break lever switches. From this 220-volt, low-tension, 'bus lead-covered feeders are supplied through automatic oil switches of the hand-operated type, mounted on the back of the panels, and distribute the current throughout the whole station, with individual motor switches and starters mounted adjacent to the motors. The oil switches in these low-tension feeder circuits are automatic and fitted with overload release without time-limit attachments.

*(To be continued.)*

## THE WORLD'S PROGRESS IN TELEPHONY.

### An Interview with Mr. John Hesketh.

Mr. John Hesketh, electrical engineer in the Postmaster-General's Department of the State of Queensland, being on the eve of his departure for Australia after an extensive tour in the United States and Europe, chiefly devoted to the study of telephone systems, the *Electrical Engineer* decided to obtain the benefit of some of the store of information on telephonic progress which Mr. Hesketh has accumulated during the past few months. Mr. Hesketh was specially deputed by the Postmaster-General of Australia to attend the International Electrical Congress at St. Louis, and to investigate the working of the telegraph and telephone systems in America and Europe for the purpose of preparing an official report for the guidance of the Commonwealth authorities in developing the Australian telegraph and telephone systems.

Mr. Hesketh is well known to many of our readers, and for the sake of those who have not met him personally we may say that he is the typical electrical engineer—alert of demeanour, clear-headed and quick of thought, and with a ready faculty of putting his impressions and opinions in a simple and straightforward manner. Our representative fortunately caught Mr. Hesketh with a free hour among a series of engagements lasting from early morning to late at night, and opened the ball as follows:

"Mr. Hesketh, the *Electrical Engineer* understands that you have devoted several months to a study of telephone work in America and Europe, and wishes, for the benefit of its readers, to know where you have been, what you have

Digitized by Google

seen, what you think of it all, and what you are going to do when you get home?"

"Rather a large order, but I will endeavour to fulfil at least a part of it. Landing in America, at San Francisco I investigated the telephone business in the principal American cities from the Pacific to the Atlantic coast, visiting 20 cities in all, including such representative American towns as San Francisco, Salt Lake City, Chicago, St. Louis, Detroit, Cleveland, Buffalo, Grand Rapids, Boston, Rochester, New York, Philadelphia, and Washington. I visited 20 large cities in all and some smaller places, and in every place where there were two competing telephone systems I examined both. In Europe I have spent some time in this country, visiting, besides the Metropolis, Glasgow, Newcastle, Liverpool, and Hull, and in these places also I have visited both telephone systems where two existed. On the Continent I have swung rather a wide circle, taking in Antwerp, Brussels, The Hague, Copenhagen, Stockholm, Berlin, Warsaw, Vienna, Budapest, Munich, Zürich, and Paris."

"You certainly have not wasted much time; and what, may I ask, is your general impression as to the progress of telephony?"

"America undoubtedly leads the world, both in the general development of the telephone business—that is, in the amount of use made of the service by the public—and in the technical development of the industry. The long lead in telephone engineering which America holds over the rest of the world stands out most clearly, and in Europe the best work is being done where American experience is being followed. It seems from the general history of the telephone business in America that the American people, as a whole, take more kindly to the telephone service than the peoples of Europe. They are more ready to avail themselves of improved means of communication, and every improvement in the service and every increase of facilities is readily taken advantage of. As an illustration of the extent to which the use of the telephone is developed in America, I did not sleep in a single hotel in the course of my wanderings where there was not a telephone in my room from which I could use not only the city service, but the suburban and long-distance service as well. It is of enormous convenience to a traveller to be able to talk to any place in the country from his own room in an hotel. In this country, and in Europe generally, hotel managers do not seem to think it worth while to provide their guests with such facilities."

"Then, how about the development of the service among the general public?"

"In American cities the telephone development has already reached a point which seems hardly to be realised as within the bounds of possibility in most European countries. In one place I found a development of 23 telephones to every 100 inhabitants. In large cities, like San Francisco, there is a development of 12 telephones to every 100 inhabitants. In every place the annual increase in number of telephones in use reaches large figures. Apparently there is no limit in sight. It is clearly evident that with a good service and a proper scheme of rates a development of 10 per cent. of telephones to population may easily be attained, and indeed the more general idea of American telephone engineers to-day is that a probable development of 20 per cent. should be provided for."

"These are bold ambitions, Mr. Hesketh? What is the American recipe for obtaining such a general use of the telephone?"

"They do not seem bolder than the established facts warrant. The principal ingredients of the recipe are an efficient service, a graduated tariff, and a thorough education of the public in the value of the telephone service."

"By what method do you find the most efficient service is given?"

"The most interesting result of my investigations is the fact that the common battery system is now accepted by telephone engineers all over the world as the correct principle of telephone exchange working. In America practically the whole telephone service of the country is worked by the common battery method, and in Europe it is being generally introduced, and wherever it is not introduced the reason is merely some question of local or internal expediency, and not because the responsible engineers do not believe in it."

"This makes the prospects of the manufacturers of the system very pleasant?"

"Every telephone manufacturer is making common battery apparatus to-day. The common battery method of working is rather a principle than a particular system. In fact, there is a wide range of systems for a telephone administration to choose from, and although the general method of working and the general results are approximately the same in all systems, the details of the apparatus and the means for accomplishing the results differ very widely. In America there are many large telephone manufacturing concerns who all make common battery systems, some of them having two or three systems differing in details. In Europe the principal large manufacturers of telephone apparatus are also taking up the common battery method, and are introducing systems which follow those of America along their general lines."

"We must take it as proved, then, that common battery working has asserted itself as a general principle?"

"Undoubtedly. No new telephone systems are being designed to-day except with common battery working, and right here in London we see the whole London system gradually being converted to common battery working. The work now being done by the Post Office and by the National Telephone Company will eventually give London a thoroughly modern telephone service. But, of course, London is unique among the large cities of the world, and the magnitude of the work to be accomplished in changing the existing system and in extending a new system to all parts of the enormous area of London will take some time."

"On the Continent generally, did you find the same views held as to the use of the common battery system?"

"Quite unanimously, and the practical proof is to be found in all the new work. Within the last year or two several of the Continental telephone systems have been rebuilt on common battery lines. At The Hague, Brussels, Budapest, and Warsaw I found complete new common battery systems in operation, and giving every satisfaction, and I also ascertained that all new work in practically every country on the Continent is to be done along the same lines."

"That is very interesting. Now, Mr. Hesketh, there has been a good deal of discussion of the telephone question in this country of late, and I should like to ask you what you consider the most important features of the telephone business?"

"I should place, for a proper consideration of the telephone business, the question of efficiency and development first, and the question of rates second. The universal experience is that the public of big cities want an efficient service, and want it widely developed. As to rates, the proper principle undoubtedly is a graduated tariff, under which the user pays according to the amount of his use. It is a great mistake to base the telephone service upon a low flat rate for unlimited use. The independent telephone companies throughout America are now realising the mistake they made in basing all their business upon low flat rates. They have not only found that to give an efficient service and to develop it rapidly costs more than they had anticipated, but they have found that the flat rate is wrong in principle, and that graduated rates are correct, both in theory and practice. As a consequence the independent companies are now generally trying to raise their rates and to introduce message rates; but it is much easier to talk about raising rates than to induce the public to pay a higher rate when once they have become accustomed to a low figure."

"When you speak of graduated rates and paying according to use, do you mean a strictly message rate, a payment for each call?"

"There are various ways of graduating the rates for telephone service, but they all amount much to the same thing—that you vary the supply of service according to the requirements of the user and charge him approximately in proportion to his use. Party-line rates are an accepted method of graduating rates. Message rates on direct lines give the user the best quality of telephone service, and the

Digitized by Google

payment is regulated merely by the quantity of service used. The most complete arrangement for supplying telephone service on a large scale is the private branch exchange, which is specially adapted to the requirements of large business concerns and hotels and residential buildings. With a private branch exchange, every user of the service has a telephone on his own desk or in his own room, and the operator at the branch switchboard acts as a distributor of the traffic and all calls go in and out to the right people, so that there is a minimum of delay and friction in the use of the service. In America the private branch exchange method of supplying the service to large users has been very highly developed, and in the cities all large business establishments and all hotels and flat buildings have their branch exchanges, some of them serving several hundred telephones under one roof. One hotel in New York has over a thousand."

"Astounding! Then you are a believer in party lines."

"As a proper means of graduating rates, certainly. You may put it in this way. The party-line telephone station, as a talking machine, is precisely as efficient as a direct-line station, but necessarily where you have several stations on one line, only one can use the station at a given time. Therefore, a subscriber having a party-line station cannot have the unrestricted use that a direct-line subscriber can have. But he does not want it, or rather, he does not feel the restriction. The party line is specially adapted to the small user, and it is practical experience that very little trouble or friction arises from the calls of two party-line subscribers coinciding. I do not believe, however, in trying to make party-line service as attractive as direct-line service. In party-line service you are supplying something at a low price for the customer who is not prepared to pay the full price for the best facilities. If you try to make the party-line service as good as the direct-line service, by introducing selective ringing and lock-out devices, you complicate your apparatus and so increase your cost of maintenance that you lose the benefit of the economy resulting from putting several stations on one line. Some of the devices for party-line working seem to me to carry matters too far in this direction. A reasonable arrangement, in my opinion, is selective ringing on two-party lines and semi-selective ringing on four-party lines. On the two-party line each subscriber would only hear the bell when he was called, and on the four-party line each subscriber would hear a call for one other subscriber as well as his own call."

"How about 10 and 20 party lines?"

"There you give an admittedly cheap service, and you cannot even try to make the service resemble direct-line service. You necessarily have code ringing, and the subscribers must learn to distinguish their own signals. But the advantage of the 10-party line is that it enables you to develop the service among small users who will not pay for direct-line service and would not use the service at all unless they got it at cheap rates. With this class of service an enormous development has been made in the western part of America and in the rural districts. My own view is that 10-party lines should be used only in country districts, not in cities."

"Are we going to do away with the telephone operator, Mr. Hesketh, and make all our calls by playing a tune on a set of buttons or twirling round a dial?"

"The automatic exchange is certainly looming large on the telephonic horizon. There are at least half a dozen automatic systems which have been worked out with great ingenuity. So far, however, only one of these has received any trial in practice. At Grand Rapids, Michigan, I saw an automatic exchange doing steady daily service with over 6,000 lines in service. This exchange has been in use now just about a year. It is giving a good service, and the subscribers seem to like making their own calls by 'twirling a dial.' Whether the automatic exchange will eventually supplant all other methods is more than doubtful, however. The weight of evidence of the great majority of telephone engineers, though all recognise the ingenuity displayed in the automatic systems and the advantages of automatic exchanges under certain conditions, is in favour of the straight common battery system. It must not be forgotten that the common battery system is already largely automatic in its operation, and it will doubtless become more so as further improvements are made. The probable development will be to place more automatic devices in the hands of the operator, and to maintain the subscriber's station in its present state of simplicity, where all the subscriber has to do is to remove and replace the telephone."

"Among all the telephone systems that you have seen, Mr. Hesketh, which should you say is the most complete?"

"Without any question that of New York. The New York telephone system is the finest example of thorough telephone engineering I have seen. All the exchanges are equipped in a uniform manner, all are in fireproof buildings designed specially for telephone purposes, the cable distribution is, for the greater part of the city, so carried out that the lines are in lead-covered cables, practically the entire distance between the exchanges and the subscribers' premises, and the service in all respects is at the very highest point of efficiency. The actual development of the service is not so high as in some of the western towns of America; but, nevertheless, the New York system is by far the largest telephone system in the world, serving actually over 150,000 stations, and is undoubtedly in all respects the best equipped. London will in time have a telephone service similar to that of New York, as the work is being carried out much along the same lines, but the area of London is immensely greater than that of New York, and the work of building a complete distribution system for a city covering over 600 square miles is a task of appalling magnitude and cost. As far as it has gone, the London telephone work is of the highest order."

"There has been a certain amount of discussion on the work done in the municipal telephone systems in England, Mr. Hesketh. Have you had an opportunity of inspecting any of these systems?"

"Yes, I have seen one or two of them in the course of my travels, but I would prefer not to express any opinion."

"That is unfortunate, but an interviewer must be content with what he can get. Do you expect to do much telephone work in Australia, and are you going to buy your telephone material in this country?"

"I expect that in the near future we shall lay our plans for a big telephone development in the Commonwealth. I am quite convinced that in any town or city a development of at least 10 per cent. can be attained in the normal course of affairs, and that a telephone system ought to be planned from the beginning to provide for that development. I hope we shall lay our plans in Australia on those lines. As to buying our material in Britain, we shall hope that British manufacturers will be able to supply what we want at the right prices. I am frank to say, however, that at the present time they hardly seem to have kept up with the procession in the manufacture of telephone apparatus suitable for large telephone systems."

"I suppose you also paid some attention to telegraph matters?"

"Yes. The principal object of my trip was to study the telephone business, but I have naturally paid some attention to telegraphy, and I can sum up my impressions in telegraphy very succinctly. What Britain has to learn from America in telephony, undoubtedly America can learn from Britain in telegraphy. As a Britisher it is very pleasing to me to be able to say this, but I think without any doubt that the telegraph system of Great Britain is, for general efficiency, far in advance of anything else in the world. The Telegraph Department has done some notably fine work in the last few years in laying long underground telegraph lines through the country. When I left this country in 1896 I should not have believed it possible that I should ever see quadruplex working on an underground line between London and Leeds."

"How do you account for the difference in the relative standing of the two countries in telegraphy and in telephony?"

"Well, broadly speaking, telegraphy is a native of Britain and telephony is a native of America. In the early days the telegraph was undoubtedly developed along more scientific lines in Britain than anywhere else. With the rapid extension of land and submarine telegraphy a band of telegraph engineers and inventors arose in this country

Digitized by Google

and have made a deep impression on the art of telegraphy. Similarly, the telephone from the beginning has been more rapidly developed, both from a business and from a technical point of view, in America than anywhere else, so in America there has sprung up a band of telephone inventors and engineers who have made a distinct art of telephone engineering. It is only a natural result that with so many minds constantly working on all the problems of a new and progressive art that there should be a rapid and constant development in the scientific branch of the work."

"I suppose you have not entirely neglected wireless telegraphy?"

"I have looked into all the different systems, but that would be too long a story, and I have an appointment now which I really must keep."

With wireless telegraphy, therefore, the interview came to an end, and the interviewer proceeded to make the best he could from an hour's rapid talk and voluminous notes.

## MUNICIPAL PURITY IN SYDNEY.

We have just received from a correspondent in Sydney a long account of a municipal trouble in connection with the Lord Mayor-elect, which reminds us of what happened in Manchester in 1900. From the issue of the Sydney paper called *Truth* for Christmas Day we gather the following particulars, which are of general interest. It seems that at a special meeting of the City Council held on the previous Thursday, counsel's opinion as to the position of Alderman Taylor, the Lord Mayor-elect, was read. We quote from our contemporary:

The case prepared by the city solicitor, and submitted to counsel for opinion, set forth that the firm of Allen Taylor and Co. supplied material to the following firms, contractors to the City Council: Edward Eagar, wood blocks; Lane and Peters, wood blocks; Henley, Limited, timber for troughing electric light cables; H. M'Kenzie, timber for general contract; Stewart and Co., timber for electric light station; Goodlet and Smith, cement.

Counsel was asked to advise whether, on the facts set out, Alderman Taylor had been disqualified at any time during the past two years, or whether he is now disqualified, under Section 24 of the Sydney Corporation Act of 1902, from holding any civic office.

Sir Julian Salomons's opinion was to the effect that at no time was Alderman Taylor disqualified, inasmuch as he was not engaged or interested, in a legal sense, in any of the contracts submitted for consideration.

The opinion having been read, the Lord Mayor moved: "That the opinion of Sir Julian Salomons be received."

After this motion had been seconded a heated debate followed, which we do not propose to refer to even in abstract. The conclusion of the matter, however, was that the Lord Mayor's motion was passed. Some ratepayers have since petitioned for the use of the town hall for a public meeting to consider the bearing of Section 24 of the Sydney Corporation Act, 1902, on the case. This section reads as follows:

Any person who, while holding any civic office under this Act, continues to be or becomes directly or indirectly, by means of partnership with any other person, or otherwise howsoever knowingly engaged or interested in any contract, agreement, or employment, with, on, or behalf of the Council, except as a shareholder, but not being a director in any joint-stock company, shall be liable to a penalty not exceeding £100 nor less than £50, and shall be for three years thereafter disqualified from holding any civic office.

It would be useless for us at this distance to express an opinion which would be at all valuable in the present case. If our readers will refer to our issue of Dec. 13, 1901, on p. 842 they will find a full statement of the laws of England on the matter. In this respect, however, the law is sometimes exceedingly hard on individuals, while lax on shareholders of limited liability companies. Thus, a member of a council may be the largest shareholder in a limited liability company without incurring any liability for actions which as a private individual would disqualify him from his seat. We cannot do better than close this brief reference to the Sydney trouble with a paragraph from our article of 1901: "There must be give and take, live and let live, in all municipal and public life. It is idle to suppose that a man when he gets into a councillor's chair can get rid of all his personal feelings of friendship and divest all prejudices, all sympathies and antipathies, when he takes off his coat and hat to go into the council-room. The idea is ridiculous. We do not want angels, but men of business to conduct our affairs, and so long as they are conducted in a business-like way, and the work is well done, we see no reason why the interests of contractor and of councillor are not perfectly compatible with the public welfare."

## FORTHCOMING EVENTS.

FRIDAY, FEB. 10.

**Olympia.**—Opening of motor exhibition.

**Physical Society.**—At 8 p.m., "Radiation Pressure," by Prof. J. H. Pointing.

**Institution of Civil Engineers (Students' Section).**—"The Reconstruction of the Santa Lucia River Bridge, Uruguay," by Mr. P. J. Risdon.

**Tramways and Light Railways Association.**—At 8 p.m., annual meeting.

**Electrical Contractors' Association.**—At 8 p.m., meeting at Frascati's upon London County Council wiring clause.

SATURDAY, FEB. 11.

**Junior Institution of Engineers.**—At 7 p.m., coming-of-age dinner at the Hotel Cecil.

**Birmingham Electric Club.**—At 7.30 p.m., "Starting and Speed Regulation of Motors," by Mr. E. R. Wood (in substitution for Mr. Whitehouse's paper).

**Institution of Electrical Engineers (Students' Section).**—At 2.45 p.m., visit to the General Post Office Central Telephone Exchange.

MONDAY, FEB. 13.

**Institution of Mechanical Engineers (Graduates' Association).**—Special lecture, by Dr. J. T. Nicolson, on "Results of Force Measurements with Cutting Tools and their Application to Lathe Design."

**Society of Arts.**—At 8 p.m., "Internal-Combustion Engines," by Mr. Dugald Clerk.

**Junior Institution of Engineers.**—At 6.30 p.m., visit to the Brockie-Pell Arc Lamp Works.

TUESDAY, FEB. 14.

**Institution of Civil Engineers.**—At 8 p.m., "Alfreton Second Tunnel," by Mr. E. F. C. Trench; and "The Reconstruction of Monoreiffe Tunnel," by Mr. D. McLellan.

WEDNESDAY, FEB. 15.

**Chemical Society.**—At 5.30 p.m., general meeting.

**Institution of Civil Engineers.**—At 2.30 p.m., students' visit to the electricity generating station of the Underground Electric Railways Company of London, Lots-road, Chelsea.

**Institution of Electrical Engineers (Students' Section).**—At 7.30 p.m., "The Electric Furnace," by Mr. W. J. Williams.

**Royal Meteorological Society.**—At 7.30 p.m., "Report on the Phenological Observations for 1904," by Mr. E. Mawley; "Observations made during a Balloon Ascent at Berlin, Sept. 1, 1904," by Messrs. H. Elias and J. H. Field; and "The Winds of East London, Cape Colony," by Mr. J. R. Sutton.

**Institution of Electrical Engineers (Birmingham Section).**—At 7.30 p.m., "Applications of Electricity in Mines," by Mr. A. C. Anderson.

THURSDAY, FEB. 16.

**Royal Institution.**—At 5 p.m., "Recent Work of the Geological Survey," by Prof. J. J. H. Teall.

FRIDAY, FEB. 17.

**Royal Institution.**—At 9 p.m., "High-Power Microscopy," by Mr. J. W. Gordon.

**Institution of Mechanical Engineers.**—At 8 p.m., discussion on adjourned papers. Prof. W. E. Lilly will read a paper on "The Strength of Columns."

**North-East Coast Institution of Engineers and Shipbuilders.**—General meeting at Newcastle.

**Institution of Electrical Engineers (Manchester Section).**—Messrs. S. L. Pearce and H. C. Gunton will read their paper on "Manchester Tramways Power Supply" on Feb. 21, instead of Feb. 14.

## APPOINTMENTS VACANT.

**City Engineer,** Wakefield.

**Switch-Room Superintendent,** Glasgow Telephone Department. See advertisement.

**Junior Shift Engineer,** Dover. Salary £80 per annum.

**Shift Engineer,** Southend Corporation. Salary £2. 2s. per week. Applications by Feb. 15.

**Chief Assistant Electrical Engineer** Battersea.

**South London Electric Supply Co.**—The directors recommend a dividend on the ordinary shares at the rate of 4 per cent. for the past year.

*Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to* C. H. W. Biggs, *139-140, Salisbury Court, Flee Street, London, and be crossed "Union Bank."*

*Bound Volumes of* "The Electrical Engineer," *containing half-year's copies, bound in Dark-Blue Cloth, Gold-Lettered, price 8s. 6d. New Volume, July to December, 1904, now ready.*

## FIRES IN COUNTRY HOUSES.

The cause of fires in country houses is frequently untraceable, and hence such fires are due to electric lighting. This is the argument which is only too frequently used in the daily Press, and even an article by an expert on the editorial staff of the *Daily Telegraph* leaves the same impression in the mind of the reader. This article points out that such "occurrences have become so numerous that, while an isolated instance might not attract more than a passing thought of regret from those with no personal knowledge of or association with the scene of the conflagration, their rapid sequence compels the surmise that some general cause must be responsible for the outbreaks." The author goes on to indicate the invaluable art treasures which have recently been lost or imperilled by fire, and uses these to show that the whole nation is interested. This is so because in nearly every case the public is at certain times admitted to view these art collections and historic heirlooms. He proceeds: "As a rule, the possibility of discovering the cause of a fire is destroyed by the conflagration itself, and 'unknown' is usually found entered under this head in the official report. But with regard to the recent outbreaks in country mansions there is a very strong disposition among those interested to lay the responsibility upon the electric lighting." Again and again charges of this kind have been brought in the daily Press against electric lighting, and frequently a subsequent examination of the scene of the fire has proved that electricity has not been responsible in any way. Unfortunately, however, the first report is widely circulated throughout the Press, while by the time the actual cause of the fire has been discovered, interest in the same has declined, and the true explanation receives a very limited circulation. This was the case in connection with the fire not long ago at Sandringham, which was first stated to be an electric one. This was subsequently proved to be incorrect, and yet quotations from the first report are regularly met with in the daily papers when announcing the probable cause of other fires. This spreading of conjecture is a feature very difficult to prevent with modern systems of news distribution, and it leads to the false conclusion with which we commenced this leader—*i.e.*, that any unknown source of a conflagration must be electric. This conclusion is as unsound logically as an assumption that only one disease is responsible for the death of all country gentlemen. The fire risks in old houses are many, and while we do not object to the dangers of badly-designed electric wiring executed with inferior materials and workmanship being pointed out, we strongly resent any general conclusions which obviously neglect the other fire risks which are more common. The author of the above article was, however, not content with a general conclusion based on unknown causes of fire, but proceeded to give his views on electric wiring as found in country houses. Coming to detail, he naturally must expect criticism, and this was amply provided by letters in the next issue of the *Daily Telegraph*. Thus he condemned wood casing as dangerous, and was promptly met by two of our leading experts in country house work, who gave figures to show the superiority of such wood casing over steel tubing except under special conditions. Into these details we do not propose to go, but trust that in this instance the readers of the article will make a point of reading also the expert criticism on the same. The substance of this criticism is briefly as follows: given a well-designed system of wiring executed with the best materials and workmanship, there is absolutely no fire risk incurred from electric lighting. It is also advisable to have regular inspections made of the wiring to see that all is in order and that no temporary

Digitized by Google

additions have been made by incompetent people. The true test of the safety of electric lighting as compared with other illuminants is to be sought in the returns from underwriters, fire offices, and fire brigades, in which there are given the actual number of fires which have been traced to different causes. Thus the fire brigade returns for the last year issued show that in London there were seventy-four fires at which loss of life occurred, but not a single one of these was due to the use of electric light.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### MOTOR 'BUSES—OR WHAT?

SIR,—I think the writer of the leading article in your last issue, entitled "Motor 'Buses—or What?" is altogether wrong in what he says about the London 'buses. I get about the busy parts of the town very much, and only know of the presence of these 'buses by seeing them. I have, I suppose, not seen all types, but those I have seen I can unhesitatingly declare are even less noisy than the horse-drawn 'buses. Since reading your article I have been paying some attention to these latter, and the wheels, the horses' hoofs, and the chain traces all make a noise. For silence I can point to the Road-Car Company's steam 'bus running from Shepherd's Bush to Oxford-circus—so graceful is this 'bus in appearance and running that it always reminds me of a Thames steam-launch—and the bigger 'bus that comes round by Charing Cross and goes up somewhere North. I think it is one of Tilling's. I have, however, had my nerves distracted and my olfactory sense offended by some of the transport motorcars. I remember a particularly bad case in Fenchurch-street recently. A few such would be pandemonium, indeed, and the stink was left for yards behind. I think I could name the company this belongs to, and I met a similar one quite recently somewhere else. I feel sure that many commercial cars are far noisier than the 'buses, and we cannot have a quantity of these soon enough when we consider the life of a 'bus horse. I am not connected with any 'bus company, and my opinion may not be that of other people, but I do feel that your leading article is wrong, and apt to mislead those who do not live in London.—Yours, etc.,

W. F.

Feb. 7, 1905.

### DESTRUCTORS AND ELECTRICITY.

SIR,—Owing partly to the publication of a very instructive paper read by Mr. W. P. Adams before the Institution of Electrical Engineers, public interest in the above question has been considerably stimulated. I think, therefore, that it may not be out of place to point out, with your kind permission, some misconceptions which may arise. There is a tendency in some quarters to estimate the efficiency of any particular destructor by the number of electrical units per ton of refuse which are produced in the works where such destructor is in use.

The number of units which are produced per ton of refuse burnt depends chiefly on the following factors: (1) the calorific value of the refuse; (2) the conditions as to day and night load, which determine whether all the refuse is used for steam raising, or whether the destructor is working at full power, while the electricity plant is practically idle; (3) the efficiency of the electrical generating plant, which may require more or less steam per unit generated; (4) the efficiency of the destructor plant with its boilers and flues; (5) last, but not least, the efficiency of the management.

It is, therefore, absurd to attribute to the destructor either the whole credit for a good result in units per ton or the whole blame for a poor result, and this is demonstrated by the fact that you will find one destructor of a given make giving a very high figure, and another destructor of the same make, but under different conditions, giving a low figure.

One of the most important factors in the efficiency of a destructor—the cost of labour—is usually ignored when using with steam-raising results. In any destructor, increased steam-raising results can usually be obtained by putting on increased labour and "stoking in spoonfuls." From the steam-raising point of view, the all-important question is, what is the cost of a ton of steam produced by the destructor in ordinary everyday work? Under the heading "Steam from Refuse and its Cost," the *Electrical Magazine* published on April 26, 1904, some interesting figures showing the cost of labour per ton of steam, as well as the evaporation per pound of refuse, at a number of combined stations. It was shown that those stations where the highest evaporative results are obtained are not always the most economical, owing to the large expenditure in labour, and it is noteworthy that among those stations where utilisation of steam is complete the best result came from Fulham.

If the destructor produces a supply of steam at a reasonable cost for labour, it is for the electrical department to utilise that steam, and the credit for good results and the blame for bad results belong by rights to the engineers who are responsible for the construction and management of the whole combined works, and not to the maker of any particular part of the installation. I think that if the above facts were more generally recognised it would be in the interest alike of electrical engineers, destructor builders, and the public, and would tend to discount a good deal of humbug.—Yours, etc.,

F. L. WATSON, A.M.I.C.E.

### ALUMINIUM.

SIR,—In reply to the letter of your correspondent, "R. T." Within the ordinary limits of cable insulation, the insulation resistance may be taken as varying directly as the thickness of the dielectric employed. For instance, if a curve is plotted having for abscissæ thickness of insulating medium in millimetres and for ordinates resistance in ohms, the "curve" will be practically a straight line. Taking, now, the relative diameters of copper and aluminium as 1 : 1·3, the leakage areas will also have the same ratio. The periphery of a circle varies directly as its diameter, and the leakage area is represented by the surface of the metallic conductor. Therefore, as the leakage area of aluminium is to the leakage area of copper as 1·3 : 1, the thickness of the insulating medium, for equal leakage, should *not* be 1·3, but $(1·3)^2$.—Yours, etc.,

WILLIAM SMITH.

Birmingham Electric Club, Feb. 4, 1905.

## "IGRANIC" STARTING RHEOSTATS.

The Sturtevant Engineering Company, Limited, of 147, Queen Victoria-street, inform us that they have recently added a number of improvements to their single and double automatic motor-starting rheostats, and are now offering to the market their latest designs under the name of the "Igranic" starting rheostats. To a very great extent the conditions which cover the design of a first-class starting rheostat have altered during the past two or three years, mainly because corporations and supply companies have been raising the voltages of the supply and offering power to consumers at maximum voltages not previously in vogue. These increased voltages have brought about more stringent rules for the protection of their network and their customers. The new conditions necessitate new types of motor starting and controlling apparatus, and it is to meet this necessity that the "Igranic" starting switches have been produced.

Briefly stated, the points which are necessary for the design of a reliable rheostat are as follows: There must be a sufficient number of contacts to ensure an easy acceleration of the motor. The starting rheostat must be provided with automatic releases to protect the motor in the event of failure of the supply, or of overloading. The resistances must be of ample carrying capacity, and must be so arranged that there is a minimum amount of sparking between the moving contact and fixed contacts. The method of assembling the resistance should be such that repairs in

Digitized by Google

cases of breakdown can be easily effected. The rheostat should be made of incombustible material throughout. No solder should be used in making the connections. The resistance box should be so arranged that inspection of its interior can be made with little trouble. Ample ventilation should be allowed to prevent any portion of the starting switch overheating, and, above all, the rheostat should be so designed as to give a high insulation resistance between any live part and earth.

The "Igranic" starting rheostats consist of a black enamelled slate front having the contacts, between which

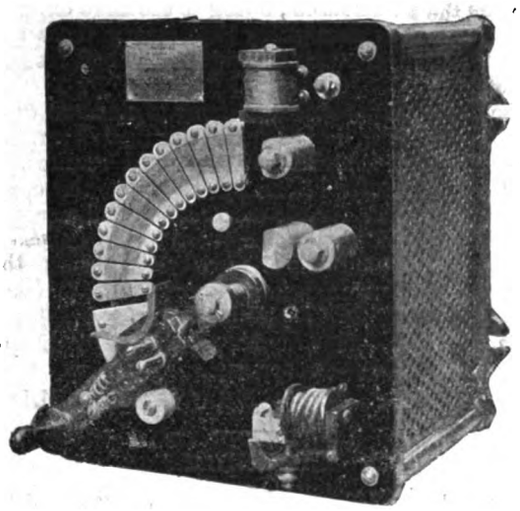

FIG. 1.—Open Type "Igranic" Starting Rheostat.

the sections of resistance are connected, mounted upon it, and a cast-iron ventilated resistance box. The contacts are of two sorts: (1) the button contact, which is used for currents not exceeding 55 amperes; and (2) the renewable contact, which is segmental in shape, used for currents exceeding 55 amperes. It is to be noted that all switches down to the smallest size can be fitted with these renewable segments, if required. The rheostat fronts are made in two patterns, one fitted with automatic no-volt release, which allows the contact arm to return to the off position, in case of failure of supply, and the other fitted with automatic no-voltage release and overload cut-out, the overload coming into effect when the current exceeds a predetermined amount. The front is provided with suitable terminals for taking the main cables, and a terminal is also provided for taking the connection from the shunt, in the case of shunt-wound machines, to the no-voltage release coil.

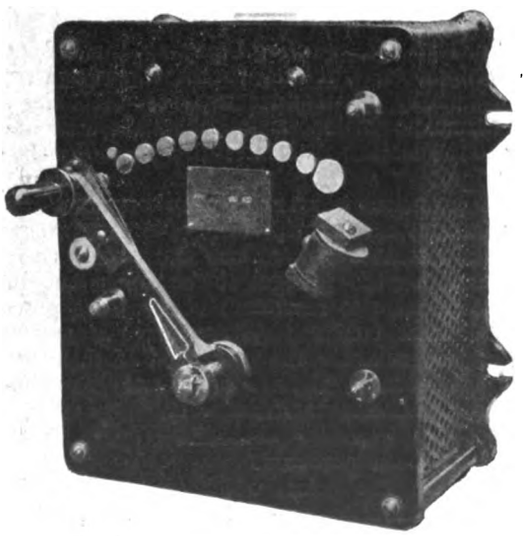

FIG. 2.—Open Type "Igranic" Starting Rheostat.

The principal feature in connection with the "Igranic" starting rheostats is the arrangement of the resistance box. The slate front described above is screwed to a cast-iron box, and insulated therefrom by means of insulating washers and bushes. The resistance material is wound upon asbestos tubes, the asbestos tubes being supported by specially formed porcelain insulators. This method of construction has proved by long experience to be most satisfactory, and provides a non-combustible, well-ventilated, highly insulated resistance. The insulators are held in specially arranged perforated supporting strips, thus ensuring a very high insulation between the resistance material and the metal box. The connections between the contacts on the slate front and the sections of resistance are made by means of specially formed clips, the connections all being made in chambers at either end of the resistance box. It is obvious that this arrangement is a very desirable one, for two reasons: (1) there are no internal connections in the resistance box; (2) every joint can be inspected at a moment's notice. The top, bottom, and sides of the cast-iron resistance box are covered by perforated sheet metal held in position by

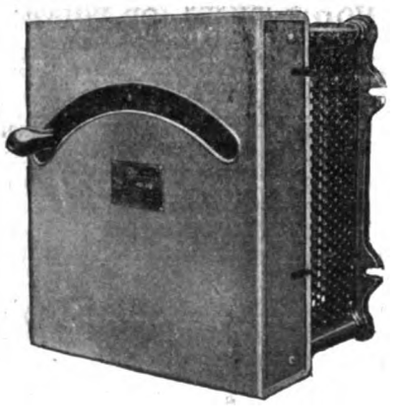

FIG. 3.—Semi-enclosed Type "Igranic" Starting Rheostat.

spring clips at the corners. It is, therefore, possible to open up and inspect the resistance box without removing a single screw, and without requiring any special tools. All that has to be done is to remove the spring clips from the corners, take away the perforated sheet sides, and the whole of the interior is exposed to view.

It will be clear from the above description that the "Igranic" starting rheostats embody simplicity and excellence of design. They are made in three patterns—namely, the open pattern, represented in Figs. 1 and 2 herewith; the semi-enclosed pattern (Fig. 3), provided with a metal cover to protect the operator against contact with any live parts; and the totally enclosed pattern, which is suitable for positions where dust, etc., would interfere with the working of the rheostat. Either can be supplied suitable for series, shunt, or compound wound motors. It remains to add that these rheostats are manufactured throughout at the Sturtevant Engineering Company's London factory, with first-class materials and the best workmanship.

## TRADE NOTICES AND NOVELTIES.

### Lighting Pillars and Transformer Tanks.

We have pleasure in illustrating herewith some useful specialities of up-to-date design and construction manufactured by the British Insulated and Helsby Cables, Limited, of Prescot,

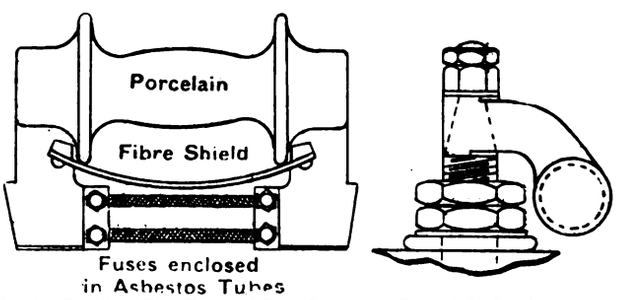

FIG. 1.—Details of Plug Fuse and Cone Connection Type of Feeder Terminal.

Helsby, and Liverpool. Figs. 1 and 2 show the details of a feeder pillar for a low-tension three-wire network. This pillar has a divided sealing base into which all hygroscopic cables enter, terminating into suitable clamps, from which rubber tails are taken to their respective terminals on the switchboard. The switchboard is composed of three enamelled slate panels for a three-wire network, one each for positive,

Digitized by Google

negative, and neutral. The positive and negative boards are placed vertically, and each is insulated from the ironwork by

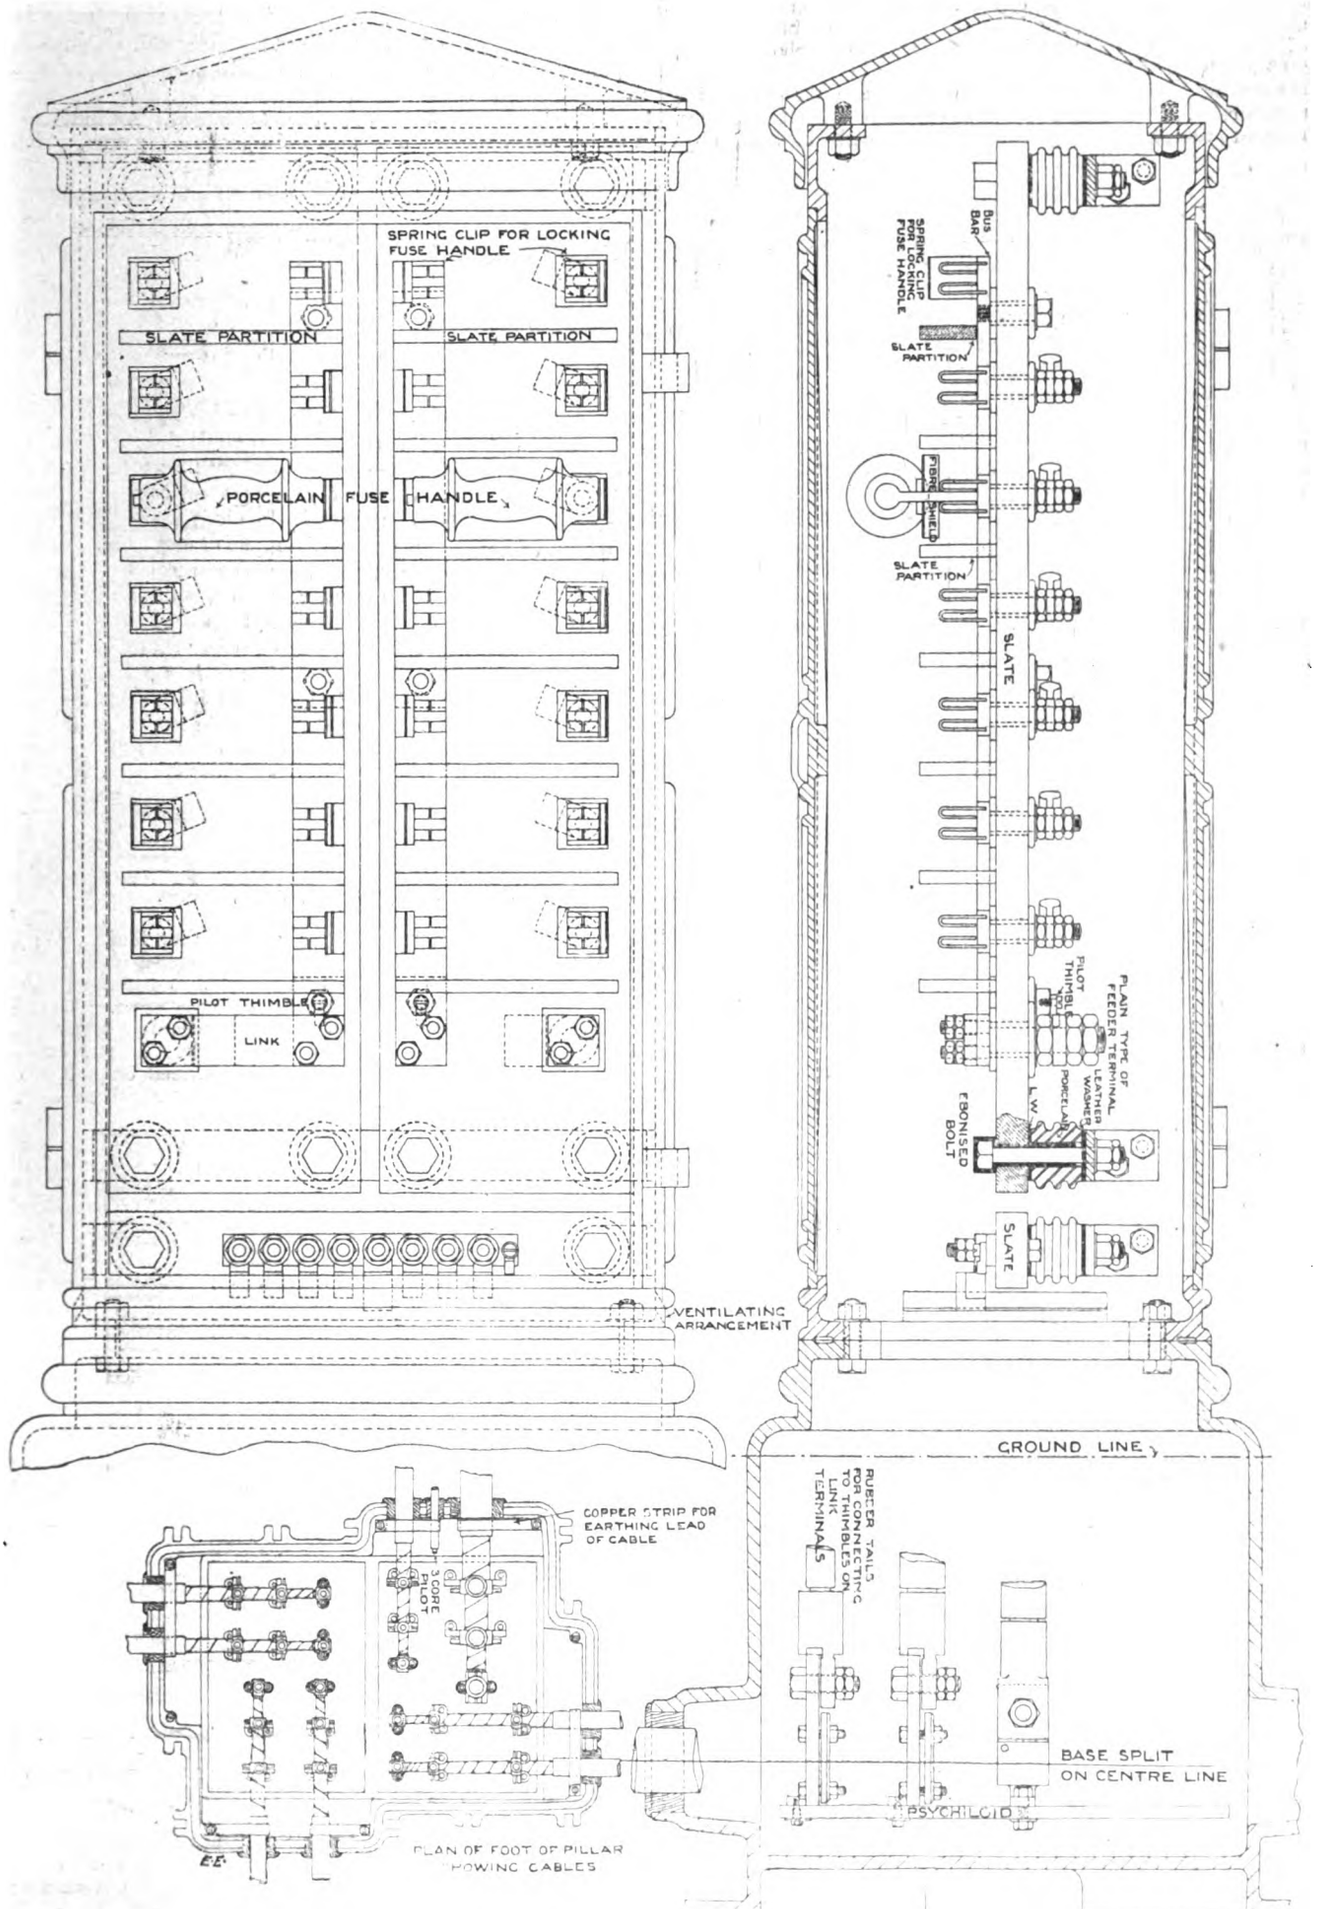

FIG. 2.—Details of Feeder Pillar manufactured by the British Insulated and Helsby Cables, Limited.

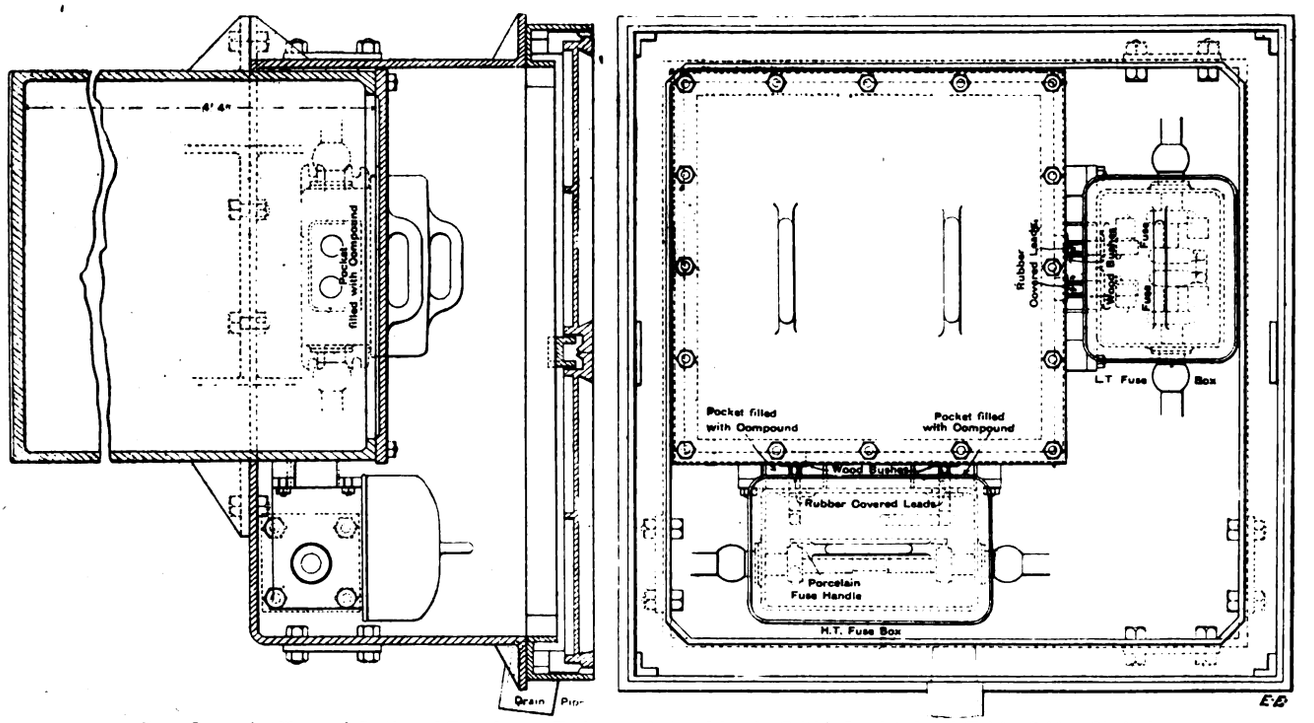
porcelain grip-handle type with enclosed fuses. The pillars are well ventilated, having inclined slots all round the base of the

non-inflammable, non-hygroscopic, corrugated insulators and insulated bolts. On each board are mounted plug fuses of the

pillar, and a continuous opening all round the base of the dome. Figs. 3 and 4 show a transformer tank, of which the firm are

Digitized by Google

supplying a considerable number at the present time we understand. Owing to the great difficulty in making brick-built transformer chambers watertight, they have directed their attention to the production of a chamber constructed entirely of iron castings; the first being the transformer tank itself, into which the high-tension and low-tension leads are taken through sealed pockets to their respective terminals on the transformer. These leads are taken from watertight boxes, bolted to the side of the tank and provided with suitable clamps and disconnecting links for testing purposes. On the outside of the tank is bolted a chamber which entirely surrounds the upper part of the tank and boxes. The top of this chamber, which is designed as shown, comes nearly level with the ground-line, and the usual pavement frame and cover rest upon it. The whole arrangement is a very convenient one, and all the fittings are easily accessible. For the rest we may well leave the accompanying illustrations to speak for themselves.



FIGS. 3 AND 4.—Plan and Section of Transformer Tank manufactured by the British Insulated and Helsby Cables, Limited.

## The Sinclair Variable Stroke Feed Pump.

Messrs. Hayward-Tyler and Co. have put upon the market a standard line of electrically-driven variable-stroke boiler feed pumps, which they are manufacturing under the Sinclair patent. These pumps, one of which we illustrate in Fig. 1, are designed to secure the highest efficiency with electrical driving. The economy of electrically-driven feed pumps over the old direct-acting steam type has frequently been commented on in our columns. In order, however, to get a wide range of output with the electric drive special devices have been adopted for reducing the speed of the motor. With the pump before us these electrical regulating arrangements are not required, as the stroke of the plungers of the pump can be varied to give different discharges while the pump is at work. The crank-shaft, instead of being fitted with cranks in the ordinary way, is provided with eccentrics, which are so arranged that their axes can be made to coincide with the axis of rotation of the shaft, or they may be removed from the centre a distance corresponding to half the full stroke of the plungers, or any intermediate distance. The change in the throw of the eccentrics is made while the shaft is rotating, simply by holding a lever or hand-wheel in one of two positions, corresponding to an increase or decrease of the stroke, and releasing same when the desired stroke has been obtained. An indicator is added which shows the output of the pump at any time, which is a great convenience when adjusting boiler feeds. With this mechanical construction an ordinary shunt-wound motor can be used, and it always runs at full speed. There are therefore no electrical losses due to regulating resistances. At the same time, there is no increase in the mechanical losses, so that the combination is efficient at all loads. In the curve (Fig. 2) we give particulars which were obtained on a 2,000-gallon pump of the three-throw type. It was driven by a 4-b.h.p. motor, supplied from a 500-volt circuit, and running at a speed of 450 revolutions per minute. The feed pump was working against 160lb. boiler pressure per minute. The over-all efficiency given is the ratio of the power put into the motor to the power represented by the quantity of water delivered against the boiler pressure. The power wasted in overcoming the resistance in the pipework system between the pump and the boilers is all included, so that the efficiency of the pump by itself would be considerably higher. The first of these Sinclair pumps have been working under commercial conditions for nearly two years, and giving great satisfaction.

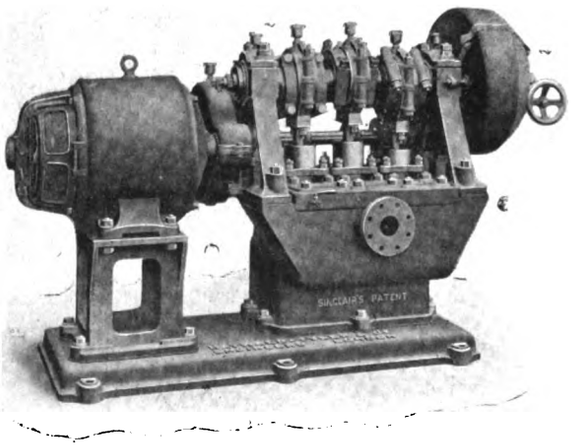


FIG. 1

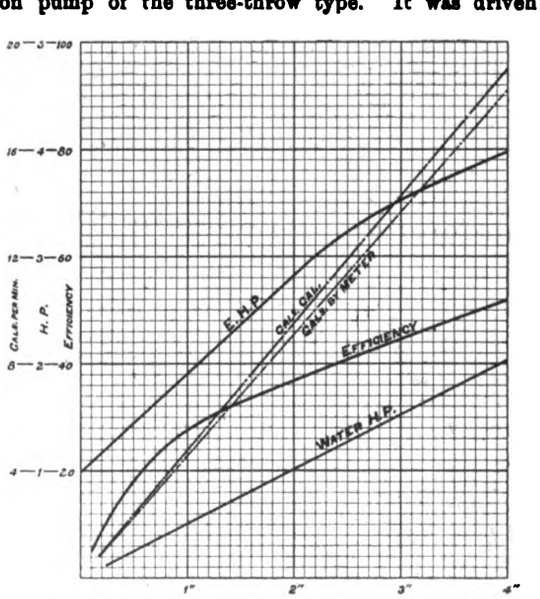

Output and Efficiency Curves of a Sinclair Electrically-Driven Feed Pump.

## "Union" Steel Interior Conduit.

The General Electric Company, Limited, 71, Queen Victoria-street, E.C., have just issued a revised edition of their conduit list, which includes particulars of several new departures. Special attention is drawn to the elaboration of their Papristeel conduit system. The paper-insulated tubes have been manufactured for some years, but hitherto no satisfactory means have been found by the company for lining the fittings. However, this difficulty has at last been overcome by using a mineral compound which is spread evenly over the interior of the fittings before enamelling. The same method is adopted

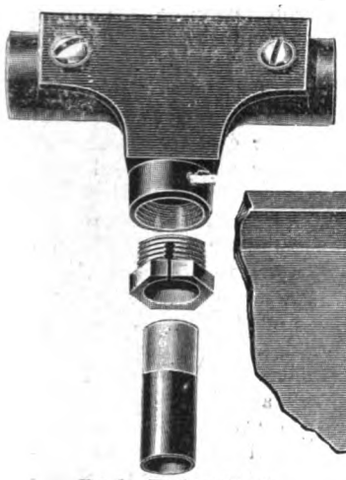

FIG. 1.—Earthing Nipple.

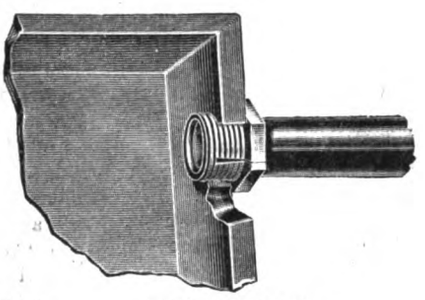

FIG. 2.—Standard Box.

with all types of joint-boxes, thus enabling much better tests to be made. Another great point claimed in favour of these insulated conduits and fittings is their reasonable price, by reason of which it is now possible, we understand, to erect an insulated conduit system for very little more than has previously been paid for ordinary screwed conduits. This result is obtained by using unscrewed Papristeel tube and insulated fittings with the "Union" patent earthing nipple (Fig. 1), which is an improvement on the soft metal nipple introduced by the firm some years ago for a similar purpose. The function of this nipple is to grip the conduit by the pressure exerted in screwing it into the fitting. It will be seen that the nipple is split through part of its length to allow for closing up tightly on the tube. Since it is necessary that these nipples should preserve their conducting properties indefinitely they are made of an alloy similar to type metal. If preferred, the conduits can, of course, be screwed in the ordinary way for watertight installation.s

Another noteworthy departure is the listing of the several sizes of plain steel boxes supplied to contractors at various times for special work. These boxes can be adapted for any number of ways, by either drilling clearing holes in them and using backnuts for clamping screwed tube, or (as shown in Fig. 2) by tapping the holes and using the patent nipples for plain tube described in the foregoing. In this connection it may be men-

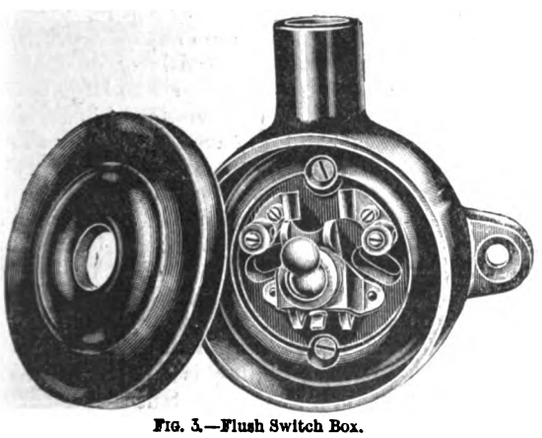

FIG. 3.—Flush Switch Box.

tioned that the company undertake to supply these boxes ready drilled to order at very short notice.

A combination switch and ceiling-rose box also calls for notice. The lugs of this box are drilled so that either the standard switches or ceiling roses can be fixed at will on the job, or transferred if necessary from one to two-way boxes.

Reference may also be made to a new and very neat design in wall-plug conduit boxes. This consists of a malleable iron box containing one of the company's "Midget" wall-plug sockets, and provided with a brass cover mounted flush. But no doubt the cover of insulating material, listed as an alternative, will be generally preferred.

Fig. 3 illustrates a useful type of flush switch box for concealed wiring. It is intended that this box should be fixed so that the edge shall come just level with the surface of the plaster. The lid then screws on to the boss of the switch, and when in position stands out only a very little from the wall.

Oval tube is also given some prominence. Our next illustration (Fig. 4) shows an adaptor by means of which an oval branch can be tapped off from any fitting in the circular main run. This is an entirely new departure, and enables the oval tube to be run direct from the fittings.

Among the accessories listed place is given to Kennedy's patent bending machine, of which an illustration is included, surrounded by bends made in brazed conduit. It is claimed that all kinds of tube can be bent by means of this machine to any required angle without heating. Two sizes are made, the smaller for bending from ½in. to ¾in. tube, and the larger 1in. to 2in. tube. We may add that particulars are included of some watertight fittings particularly adapted for use with conduits, also plain pendants and brackets, made from steel tube, for workshop and similar use. By using Union patent

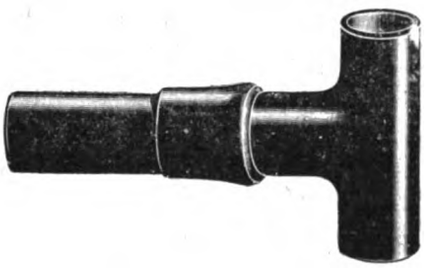

FIG. 4.—Fitting Adaptor.

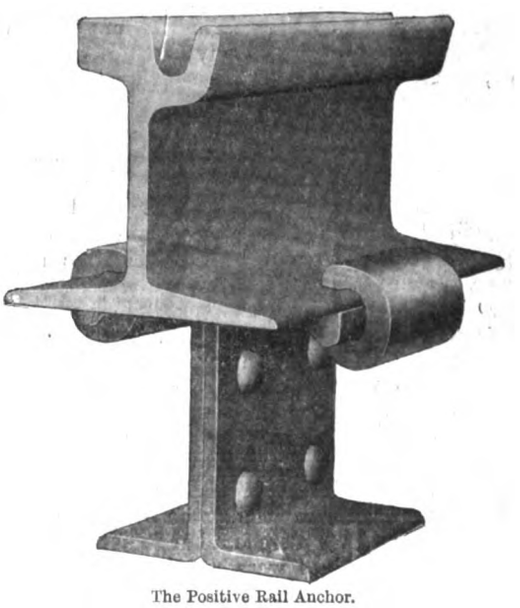
earthing nipples, these watertight fittings, which are usually screwed ½in. gas, can be immediately adapted for ¾in. ordinary conduit.

## The "Positive" Rail Anchor.

The accompanying illustration shows a new anchor (Walker and Grant's patent) for tramway rails, the rights to manufacture which have been acquired by Messrs. Naylor Bros., Limited, Golborne Ironworks, Golborne, Lancs. The "positive" rail anchor has been designed, we are told, to meet the demand for an anchor which can be fixed without drilling the rail, and is at the same time cheap, strong, and easy to fix. It resembles an "I" section with a "bulb" along each top edge, and is held under the rail by means of heavy clips driven on with a hammer in a direction parallel to the rail. The anchor itself is formed of two rolled-steel plates bent to the proper shape and riveted together; the clips are stamped out of stout steel plate and pressed round a mandril to the exact size required.



The Positive Rail Anchor.

The bulbs are formed to a slight taper, so that the clips enter easily, but grip like a vice when home. The anchor can be made to suit any section of girder rail, and may be added to an existing track with little trouble.

## Catalogues, etc., Received.

THE CAPE ASBESTOS COMPANY, LIMITED, 8, Minories, London, E.C., Kimberley, and Turin.—From the very serviceable combination blotting-pad of this firm, who are manufacturers of blue asbestos removable coverings for boilers, pipes, flanges, etc., we notice that they have a very large number of agencies in all parts of the world.

## SOME POINTS ON THE SELECTION OF ELECTRIC CABLES.

The above paper was read before the Manchester Section of the Institution of Electrical Engineers on Tuesday. The authors, Mr. L. B. Atkinson and Mr. C. J. Beaver, dealt generally with the types of cables at present in use, and as these were reviewed at considerable length, and from a somewhat technical point of view, this abstract will endeavour to deal with the main features of the paper from the standpoint of the ordinary buyer and user who prefers to note the results of experiments rather than to peruse the details of same, and who possibly considers opinions based on either practical experience or experiments to be of utility to him, even though ungarnished with tabulated data. The paper must be strongly commended for its exposure of the methods indulged in by unscrupulous manufacturers, which, though cheapening the cost or increasing the profits, tend to lower the standard of excellence that is such a feature of most English factories.

The opening paragraph, explaining the paucity of papers upon the subject, gives reasons why there are comparatively so few cablemakers in existence compared with the number of makers of other descriptions of central-station plant: A study of the proceedings of the Institution of Electrical Engineers reveals the fact that of all the important subjects relating to the practice of electrical engineering few have been dealt with to such a small extent as the subject of cables. The reason is, perhaps, not far to seek. In machines, in instruments, in switchboards, there is something which appeals at once to the inventive and constructive mind; known facts and laws may be manipulated to produce novel effects; the results are at once tangible and often striking, and the appliance may be generally readily introduced into the market with perhaps no great outlay of capital, whilst the production of cables with new dielectrics, involving laborious experiment in almost unknown regions of chemistry, requires plant and necessitates large outlay of capital. Their introduction into the market involves considerable expense, and the finding of heavy guarantees for their qualities and permanence. Then, again, electrical enterprises are generally in the hands of mechanical engineers, and the design, manufacture, and use of cables embody so many points of purely electrical and chemical knowledge that, bearing in mind that most mechanical engineers do not study these two sciences, especially the latter, it is not to be wondered at that the tendency is to accept what is given them, rather than make any careful study or enquiry into what they really should demand. Foremost among the papers on this subject which have come before the Institution was the paper on "Insulation on Cables," read in 1901 by Mr. Mervyn O'Gorman in London. This was practically the first paper treating cables from a broadly scientific point of view; and yet there was practically no discussion thereon, and so far many of the important suggestions made in it have been barren of any practical result. It is worth while for a moment to consider why this was so. To some extent it no doubt arose because the paper took so general a view of the whole question. Cablemakers found little to discuss, because their own particular products were simply accepted in the paper as existent, and suggestions, none of which had then been tried, were made for their improvement. Engineers were in the same position; for the questions with which they were familiar in the practical use and deterioration of cables were not brought at all into view. The aim of the authors of the present paper is far less ambitious. They desire to take into consideration the existing types of cable, to consider the purposes to which they are adapted, and to deal with the qualities to be sought for in each type to ensure that it may be the best of its kind.

*The Conductor* is naturally first dealt with, and this commences the series of *exposés* which is such a feature of the paper: The specification of any standard conductor should state the effective sectional area of the whole conductor, *i.e.*, the area of a solid wire having the same conductivity and the number of wires in the strand, or alternatively (as is common in the case of small conductors), the gauge number or diameter in mils of the wire, and the number of wires in the strand. It should further define the minimum conductivity allowable. In the case of tinned wires, it should also state the percentage permissible departure from the standard of conductivity produced by the tinning. Every engineer knows the enormous difference in conductivity between pure copper and copper containing small percentages of impurity. The conductivity of copper produced by ordinary smelting process may be only 50 per cent. to 80 per cent. of that of electrolytically-refined copper. Hence every engineer specifies that conductors shall be of electrolytic copper of 100 per cent. Matthiessen's standard, but in few cases, especially with smaller ones bought commercially, is this tested, and there are copper conductors in the market of not more than 80 per cent. (Matthiesen's standard) conductivity, and these are accepted and used for house wiring and other purposes without discovery.

It cannot be claimed that such wire is bought by the manufacturer as high-conductivity copper, as there is no difficulty in obtaining electrolytic copper of from 99 to 102 per cent., and for many years the only difficulties which the cablemaker has had to contend with, as affecting conductivity, have been mechanical, such as inaccuracy in drawing or imperfections which affect the homogeneity of the wire, but nowadays these are almost negligible. It may be thought that the gain to the manufacturer in making this substitution is too small to be worth considering; but it must always be remembered that the necessary fixed outlay in producing a cable is large, and it is only by variations of small percentages that profit or loss in cablemaking arises; hence a difference of about 3½ per cent. in the price of the copper is appreciable in the case of a large turnover. It is quite arguable that the margins of carrying capacity insisted upon by fire insurances and supply companies' rules are so great that such cables are quite sufficient for all requirements, but if they are the rules should be altered, and either wires admitted which, with lower electrical qualifications, give certain sizes and strength, whilst the purchaser gets them cheaper, or rigid tests should be made to ensure that all tenders are really on a similar basis.

*The Insulation* of a cable is described under three heads: (1) rubber, (2) elastic or plastic materials, (3) fibrous materials impregnated and covered with lead or waterproof material. Regarding rubber-insulated cables, the following may make the reader appreciate the necessity of conscience as an important part of the stock-in-trade of cable factories: Rubber-insulated cables were the first, and in the early days of heavy electrical engineering the only cables used, and their use to-day is still very large for all purposes where high insulation and easy fixing and manipulation are primary considerations. Indeed, except for their cost, they probably would never have been superseded. Speaking generally, there is hardly any article of general commerce in which the buyer places himself so largely in the hands of the seller as he does in the matter of indiarubber; and although large buyers often have facilities for analysis of goods, there are difficulties in the analysis of indiarubber articles which are hardly paralleled in other general analytical work, and to correctly interpret results, and to appreciate the vital points in cable manufacture, it is essential that the analyst should not only be, to some extent, a specialist in rubber, but should have knowledge of the manufacture of cables, and of the various electrical phenomena which affect the life and efficiency of cables. The importance of perfect tinning is insisted on as the best means of separating two substances—rubber and copper—which for chemical reasons should be kept apart. Details of a simple test are given in the appendix for ascertaining the value of the tinning, by immersing wire samples alternately in hydrochloric acid and sodium sulphide for definite periods of time, and then noting the blackening effect.

*Pure Rubber.*—The importance of the purity of this is dealt with, but: It is obvious that such pure rubber must be expensive. With raw rubber in the neighbourhood of 5s. 3d. per pound, the cost to the cablemaker will be about 8s. 6d. per pound. Though at the present time rubber strip, purporting to be pure Para, is being offered at 5s. 9d.

Digitized by Google

per pound. There is, therefore, little occasion for surprise to find that in foreign cables, and in cables made by firms with little or no reputation to support, the pure rubber, as above described, is substituted by a lower grade rubber, in which the requisite elasticity and mechanical properties are obtained by vulcanising by what is known as the "cold cure" method. This consists of treating the surface with chloride of sulphur in carbon bisulphide. Apart from the fact that this rubber contains sulphur, contrary to the essentials of its functions in the cable, it nearly always contains traces of hydrochloric acid as an after result of the chemical treatment. The danger of using such rubber hardly needs emphasis, but the temptation to the alien and the small maker lies in the fact that it can be produced at something like 40 per cent. less cost than pure Para strip made by the best method. In some cases of cheap cables the pure rubber may be found to contain a proportion of "rubber substitute," which usually consists of oxidised or vulcanised oil, sometimes with an addition of wax. Such adulteration is not only fraudulent, but almost as harmful as the low-grade chemically-treated rubber referred to above. Where no attempt is made to adulterate, it is sometimes found that makers attempt to imitate the hard non-adhesive surface of correctly "aged" strip by coating with a film of soapy composition. Wires coated with such rubber will blacken before vulcanising if traces of free alkali are present.

*Vulcanising Rubber.*—This compound material as usually applied in two layers of differing colours (generally drab and grey) is also subject to adulteration to a dangerous extent, as here followeth: The addition of rubber substitute, as referred to under "Pure Rubber," should never be allowed; and the expression, "containing no organic matter other than rubber," is in some specifications intended to prohibit such materials. In few cases are analysis made to check this important matter, and even when the specification is framed to bar substitutes large contracts are frequently placed without reference to anything of the kind, and the first-class firm has to be passed and orders given to possibly a foreign competitor, who does not scruple to put in his "mixings" 5 per cent., 10 per cent., or even more of a material costing anything from 4d. to 1s. per pound, in place of the hard fine Para costing from 6s. to 7s. 6d. per pound, according to the state of the market. Such substitutes are invariably prejudicial to the life of rubber cables or any other rubber goods. They increase the liability to oxidation, because they only form mechanical mixtures, and neither combine chemically nor cohere physically; in fact, they sub-divide the particles of rubber when ground up with it, and this means imperfect results as regards durability, from mechanical and from electrical points of view. It is pointed out that specifications are drafted even nowadays with sufficient vagueness to enable the unscrupulous to put in inferior material, and yet to get past the tests. An instance is quoted where a very large contract was recently passed abroad owing to the difference between "fine" Para and "pure" Para being unnoticeable to the eye of the simple foreign tenderer, and to him arranging his insulating materials so as to pass a test after *three* minutes' electrification, instead of after the more searching *one*-minute period, which, though generally understood, *was not specified.* For the prevention of local weaknesses in high-tension rubber cables, the addition of a metallic sheathing is recommended, on the same principle evidently as bonding is used for electrolysis in lead-sheathed cables.

*Fire-Resisting Cables* hardly appear to need much reference as to their suitability for certain situations, and the principles upon which their construction should be based are explained. The main qualities required are: (1) insulation; (2) flexibility; (3) waterproofness; (4) mechanical protection; (5) fireproofness; and either of the three classes of rubber, vulcanised bitumen, or guttapercha are preferred for the insulating medium to be covered by the usual tapes or braids chemically treated, so as to be incapable of supporting flame. Tanned jute is the covering best recommended, and asbestos is stated to be too mechanically weak.

*Vulcanised Bitumen.*—The weak point of this class of cable, its liability to decentralise, is discussed, but the results of tests made on three (incognito) samples of different makes showed that very little fear need be felt on this score. The permanency is, however, brought into question, and this is a point that has hardly been suspected in this class of material: The permanency of such dielectrics is, of course, an important element; it is by many thought that they are absolutely permanent, but they are so only relatively, as they all contain elements affected by various external agencies, and at least it is desirable in considering the use of such dielectrics in various situations to realise how far the possible attacking agencies may have weight. The action of the air gradually tends to oxidise and harden such compounds, particularly if they contain free oils or other oxidisable materials. Acid met with in mines, alkalies in works of various sorts, and some soils acting on other elements of the composition, have other effects. Various sulphates, acids, and alkalies were let loose upon samples of vulcanised bitumen with no effects in some cases, hardening in others, and others still were severely attacked; chromic acid and caustic soda being the most destructive agents: The results of these experiments are full of instruction as to the qualities of and uses to which this class of cable may be properly applied, and show how certain attacking and deteriorating agents not only have a surface action gradually thinning the insulating layer, but may by selective action be penetrating the mass. This latter effect would, of course, be enormously increased with cables carrying continuous currents and having earths on the circuit, on account of osmotic pressure forcing the chemical ions through the dielectric. Such action would be in some degree the equivalent of electrolytic action in lead-covered cables. This is worthy of note, as the freedom from such action is claimed as one of the strongest points in favour of the vulcanised bitumen type of cable. Regarding the whole of the above results broadly, the conclusion forced upon one is that to attain maximum efficiency in every respect vulcanised bitumen compounds must be designed, made, and applied with the greatest possible care. For instance, physical properties (such as resistance to decentralisation) must not be obtained by the sacrifice of chemical inertness. Efforts in this direction usually take the form of stiffening the compound by the addition of mineral loading matter, and, as shown above, this results in not only laying open the material to loss of coherence among its particles (and incidentally rendering it liable to fracture in very cold weather), but also encourages the action of oxidising influences and the selective actions which have been described.

*Fibrous Dielectric Waterproof Sheathed.*—The weak point of this class of cable is that, however well the fibrous material is impregnated, it is always liable to more or less readily take up moisture from the atmosphere, whereby its insulation resistance is reduced. Hence the necessity of covering with a waterproof sheath or metallic or non-metallic composition. A few words as to the protection of the dielectric when the paper is exposed for jointing, or trimmed for connection, may be advisable here. On comparatively small jobs suitable terminal ends are often omitted; pure rubber, or proofed tape, or both being frequently substituted therefor. Even in making joints, materials which are not waterproof for electrical purposes are often used. Care should be taken that only such materials as are non-fibrous and can be made homogeneous should be used. Reference to Glover's guttaroid tape for such purposes is made in a later part of this paper. The fibrous materials generally use are of two classes—viz, paper and fibre, the latter being usually jute or cotton, applied in the form of yarns and afterwards impregnated. The former usually consists of manilla paper, and comprises the great majority of cables which are now made with fibrous materials. The oils used are generally resin oils, or mixtures of resin and resin oils, while Messrs. W. T. Glover and Co. use a compound made from oils called "diatrine." This class of insulation, like its fellows, suffers from the Whitechapel taint, and the word manilla is evidently capable of as many meanings as its sellers choose to give it. In consequence of which: A combination of factors (among which may be included the above stated fact, keen competition, more or less lack of appreciation of the importance of the subject

Digitized by Google

on the part of the cablemaker, and on the part of the users or their consulting engineers, and the difficulty of constant checking of the paper manufacturer's products) has resulted in large quantities of paper cable being sold and used in the past containing small proportions of manilla (and in many cases none at all), and large proportions of straw, esparto, chemical wood, and even mechanical wood. Samples of Continental and American cables have been examined in which chemical and mechanical wood papers were used entirely, and some German makers have gone so far as to maintain that chemical wood is preferable to manilla. The chief disadvantages of the introduction of straw, grass, or wood fibres in place of manilla are as follows: (*a*) lower dielectric strength and insulation resistance, and higher capacity; (*b*) deterioration in strength and elasticity of the paper when heated continuously or intermittently, and consequent brittleness; (*c*) danger of rotting in course of time through the action of residual chemicals. Magnified photographs of some classes of manilla paper were shown on the screen, and the characteristics of the poorer classes distinguished from the better material by the differences in the nightmare-like shapes shown. A specification of paper suitable for insulating is given in the appendix. The peculiarities of impregnating compounds were touched on, the consistency recommended being plastic, but not so fluid as to run by gravity within the cable itself.

The lead-sheathing operations are considered: The lead is put on such cables in a plastic state by hydraulic pressure. This is an operation requiring such care to avoid minute cracks or damage from particles of oxide being forced in with the lead that there are engineers who still advocate the older system of drawing the cable into a lead pipe which has already been tested by water pressure, or of putting on double sheaths of lead. Messrs. W. T. Glover and Co., Limited, have, however, met the question by the use of hydraulic pressure up to 100lb. per square inch applied externally after the cable is finished. Such pressure invariably detects a fault if such exist in the lead. The ordinary tank test is practically useless, and it may take many months or even years for water to enter the very fine seams which such faults occasion, but eventually it will do so. No doubt in the past this has been the reason for many unexplained failures, while many more have been due to corrosion in various forms, the effects of which are usually difficult to diagnose, and in most cases the causes are equally difficult to trace. The chief causes of corrosion of lead coverings under working conditions may be summarised as follows: (1) impurities in lead, causing local galvanic action; (2) galvanic action between lead and adjacent metal; (3) corrosion by chemical action; (4) electrolysis.

The causes of the foregoing are reviewed. The most dangerous obviously is the last-named, and while the vagrant tramway and lighting earth currents are duly debited with their share of mischief, another less heard of cause of trouble is commented on. This is the corrosion of lead-covered cables in buildings, etc., due to the existence of a difference of potential between the lead sheathing and its surroundings: The character of the corrosion may vary from small holes which gradually penetrate the lead covering, convert the lead into various oxides of lead, and only make themselves apparent when the rubber dielectric becomes oxidised to a sufficient extent to break down, or the paper dielectric sufficiently exposed to absorb moisture and fail (which may take many months) to very extensive action and a high degree of oxidation (where there is a free and continuous supply of the electrolytic medium and a small difference of potential) or a limited amount of general corrosion, followed soon by fusion (where the supply of the electrolytic medium is small or not continuous, and the difference of potential is comparatively high). . . . In rubber cables the rubber usually fails quickly when the lead is finally penetrated, owing to oxidation; but in the case of paper cables, if undisturbed, the oxides into which the lead is converted will keep out atmospheric moisture for, possibly, years, and the effect of the liberated oxygen in the paper (if made of pure manilla only, and well impregnated) will be negligible. The opinion is expressed that lead-sheathed cables will have but a limited application in connection with heavy current work in the future, and the need for sufficiently bonding and earthing is mentioned.

A class of leadless paper-insulated cable was described as combining the dielectric strength of paper with the waterproof qualities of bitumen, and as being more suitable for heavy currents. It is somewhat disappointing to find that the paper concludes without hazarding a surmise as to the future form or type of electrical cables, but as in the past the question has principally depended upon fashion, so in the future that fickle dame may continue to exercise her control.

The matter in the appendix is really valuable as being specifications compiled by cablemakers for engineers, which is almost one of the signs of the millennium!

---

DISCUSSION.

**Mr. C. D. Taite,** from the chair, commented on the amount of original research occasioned by the paper, and on the valuable information thus given to engineers, who, as a rule, possess less information upon cables than upon any other subject. He thought the Cablemakers' Association standards were distinctly useful, and anticipated that there would now be less trouble experienced in preparing suitable specifications.

**Mr. T. L. Miller** congratulated the section upon the paper, and agreed that it added considerably to the very limited amount of information at present available on the subject. The revelations as to the cooking of cables, however, would add a new terror to the consulting engineer. He had imagined that all that was necessary was to specify the insulation resistance and the pressure test, when the cablemakers would guarantee all the rest. It pointed the moral that it was necessary to go to a reliable firm, as if cablemakers wish to "do" one, they can whether or no. He suggested that standard compounds should be devised by an independent analyst, as consultants were yet much in the dark as to the best arrangements for various conditions. He agreed that lead-covered cables had had their best days, and that vulcanised bitumen was a step in the right direction. In Liverpool district lead pipes would not stand any time, owing to the condition of the soil. He referred to a case of failure of lead-covered cable which had been laid solid with cover tiles 1ft. long, where the cable went wrong at 1ft. intervals, and he invited explanations.

**Mr. Pocklington** said that he had been waiting 18 years for this paper. He had laid a lot of cable in Liverpool, but had never found any decentralisation troubles, although his (vulcanised bitumen) cable was often overloaded. He had, however, known some cables give way due to inferior insulation mixtures. He thought that the magnified photos of manilla paper, which showed canals in each quality, almost indicated the cause of hygroscopicity by their presence.

**Mr. S. J. Watson** concurred that the paper was interesting and deserved large attention. He thought that some of the cablemakers must have waxed rich on the amount of adulteration carried on in the past as shown by the paper, but in the future buyers should be better able to get value for their money. He also agreed that lead-sheathed cables should be superseded by a leadless sheath. The past success of vulcanised bitumen, he thought, was largely due to its being generally laid on the solid system, which prevented contact with deleterious matter. He could not explain how rubber cables made by good firms had been so unsuccessful on town networks, and he could find no one else who could explain, makers included.

**Mr. Connelly** explained why separators were used in rubber cables, and gave the following rough tests for examining the quality of a rubber cable: (1) examine tinning for brightness; (2) rubber should be tough and elastic; (3) thicknesses should be up to standard; (4) a variation of between 40deg. and 200deg. should have very little effect upon the insulation.

**Mr. A. G. Cooper** emphasised the need for efficient bonding by wiped gland joints and by earthing at the station. He had found no trouble on account of oil running inside a cable through gravity.

**Mr. Harvey** said vulcanised bitumen cables were risky only when passing over bakers' ovens, and when properly laid they were O.K. His experience showed them to be the best for mining work, where the worst conditions were to be met with.

**Mr. C. C. Atchison** objected to the undue susceptibility of gas and water mains to be damaged by electric currents. His station had been running now for four or five years, and he had yet to experience the emotion of having a faulty cable on his network, but he believed he was in good hands. He was pleased to note that the C.M.A. specifications showed thicker paper and lead than previously was the practice. Considerable discretion should be used in bonding, and joint-boxes should be bonded across by something that would not act as a fuse to an excessive earth current. He thought that cement-jointed ducts caused trouble with lead-covered cables, but had known rubber-covered cables to last 10 years on alternating supply in iron pipes.

**Mr. Berry** thought cement had no effect upon lead-covered cables. The National Telephone Company had had eight years' experience of concrete ducts without a single case of deleterious action through cement. He spoke, as one interested in a new duct lined with lubricating material, of the strains met with when drawing cables into unlubricated ducts.

**Mr. W. W. Lackie** referred to the value of the paper, and to the numerous gathering compared to the Glasgow Section meetings.

Digitized by Google

**Mr. W. Taylor** considered that insulation should not be too solid, as it would be liable to be damaged by bending, particularly in cold weather.

**Mr. C. J. Beaver**, replying to the discussion, agreed that bonding and earthing should be considered upon the merits of each scheme, and that it was not advisable to invite current on to the lead sheathing. The seeming canal shapes shown on the magnified manilla paper photos were too minute to be water conductors, and he admitted that there were many peculiar shapes shown which might be likened to anything almost "except torpedo-boats." As to the tests with acids, etc., it should be noted that the severe testing conditions were arranged to the scale of about one day : one year.

**Mr. S. L. Pearce**, in proposing a vote of thanks to the authors, concurred as to the probability of lead-covered cables being used in the future more limitedly than in the past. His own investigations into the matter of bonding practice showed that there was absolutely every method in use, right and wrong, all over the country without the slightest attempt at uniformity.

**Dr. Bowman**, in seconding the vote, said that when he wanted cables he went direct to the makers, and had their experience put at his service, which he thought was the best way.

**Mr. L. B. Atkinson**, in acknowledging the vote, said that Mr. Taite had suggested the paper to him, and had worried him into promising to write it. He, in his turn, had worried Mr. Beaver into writing it, and Mr. Beaver was mainly responsible for the effort.

The **Chairman** announced that the meeting of Feb. 14 was postponed until the 21st, and the annual dinner date was also postponed by one week.

## PERSONAL.

Mr. T. B. Holliday, the engineer and manager of the Brighton Corporation tramways, has resigned that position for a similar one with the Hastings and District Tramways Company.

The recommendation of the Electricity Committee of the Manchester City Council that Mr. S. L. Pearce be appointed chief electrical engineer at a salary of £900, rising to £1,000, as stated in our last issue has been adopted.

The Bradford Electricity Committee have appointed as assistant electrical engineer Mr. Charles William Salt, of Croydon, at a salary of £250 a year.

The Dover Town Council have accepted the resignation of the station superintendent, T. McGill, and have appointed C. H. Lydall at £150 per annum, rising by £25 per annum to £200.

Mr. James Buckley, the chief assistant at the permanent-way engineer's office, Wellington Bridge depot, Leeds city tramways, has had his salary increased to £200 per annum.

We regret to learn of the death of Mr. James Edward Ransome, chairman of Messrs. Ransomes, Sims, and Jefferies, Limited, Orwell Works, Ipswich.

Mr. Frederick Coutts, general manager of the Ayr Corporation tramways, has been appointed manager of the Paisley tramways at a commencing salary of £400 per annum. Mr. Coutts, whose present salary is £250, came to Ayr from Dundee when the tramways were inaugurated in 1901, and his management of the system has been characterised by conspicuous success. His resignation has been accepted with regret.

The salary of Mr. A. P. Dryburgh, assistant engineer at Dewsbury electricity works, has been increased from £150 to £170 per year.

## LEGAL INTELLIGENCE.

### TRAMCAR ACCIDENT.

In the High Sheriff's Court at the Manchester Assizes, before the Hon. John Mansfield and a jury, the case was heard of Wiggins *v.* the Corporation of Manchester.

The plaintiff sought to obtain compensation for personal injuries received in a collision between two Manchester Corporation tramcars at a point near Singleton-road. The accident arose through one of the cars not entering a loop line in sufficient time to allow the other to pass. As a result the cars became interlocked while both were heavily laden with passengers.

The jury awarded £400 compensation.

### MOTOR TRACTION COMPANY.

In the Chancery Division last Friday Mr. Justice Buckley gave his decision in the matter of Mason *v.* the Motor Traction Company, Limited.

The plaintiff, as reported in our last week's issue, sought an injunction to restrain the company from carrying into effect an alleged agreement purported to have been entered into between the company and a Mr. F. G. Hackney, as trustee for an intended new company, or from otherwise carrying into effect a scheme for the reconstruction of the company, intended to be carried out by means of the alleged agreement. Plaintiff's contention was that the articles did not empower the company to sell for partly-paid shares in another company, as it was proposed to do. The company was incorporated in June, 1898, as the London Steam Omnibus Company, and in 1899 the name was changed to the present title.

**His Lordship** said the company had resolved to sell its undertaking for a certain number of partly-paid shares, and the sole question was whether the proposal to sell in this manner was *ultra vires*. The defendants were prepared to undertake not to carry out that part of the scheme relating to the manner of dealing with the purchase consideration without further resolution of the company. According to previous decisions, a sale might be made for partly-paid shares. There was no reason, in the nature of things, why a company, whose objects included the taking over and holding of shares, should be precluded from taking shares partly paid. The defendants, therefore, having given the undertaking stated, there would be no order on the motion, except that the costs be costs of the action.

### ACCIDENTS ON THE MANCHESTER TRAMWAYS.

#### Cross v. the Corporation of Manchester.

The plaintiff, George Cross, a cabowner, claimed compensation for personal injuries which he had sustained through a collision between a cab he was driving and an electric tramcar. Negligence was admitted, and the jury were asked to assess the amount of damages. In crossing the road on his cab he was run into by an electric car, which, counsel said, appeared to have been very negligently managed. The plaintiff, as his cab was crossing the metals, saw two cars approaching, the first of which was one of the heavy bogie cars, which struck the vehicle near the off front wheel with such force that the plaintiff was flung off his seat, falling with his head on the pavement. It appeared that the car was disabled before the accident, and had been towed into Albert-square; and it was on its way to the car-shed, being pushed forward by but not coupled up with the car behind it. Descending the slight incline in Cross-street, the car got out of control, the brakes being rendered temporarily useless by an entanglement with the trolley rope, which prevented the motorman from using them. The plaintiff claimed substantial damages, not only for his own injuries but also for damage to his cab. He was confined to bed for many weeks, under medical care, and suffered great pain.

Counsel for the Corporation having addressed the jury in mitigation of damages, the plaintiff was awarded £500.

## COMPANIES' MEETINGS AND REPORTS

### GREAT NORTHERN AND CITY RAILWAY.

The thirteenth half-yearly meeting of the Great Northern and City Railway Company took place on Tuesday at the Westminster Palace Hotel, the Earl of Lauderdale presiding. Particulars of the report appeared in our last week's issue.

The **Chairman** stated that the traffic receipts were steadily increasing, as the line was gaining in popularity. The ventilation of the tunnels and stations was very satisfactory, and the purity of the air was all that could be desired, while the temperature remained nearly uniform. With regard to working expenses, the matter was in the hands of the contractors, who were responsible for a further period of two years. Since their last meeting they had entered into a supplemental agreement with the contractors, by which the latter undertook to work the line at 60 per cent. of the gross earnings for the first year and at 50 per cent. for the second and third years. In the settlement of the accounts the contractors had met them in an exceedingly fair, liberal, and friendly spirit. The directors believed that in due time the projected extension to Lothbury would be an imperative and profitable addition to the system, but they considered it would be premature to undertake it at present, especially having regard to the condition of the money market.

The report was adopted.

### TYNESIDE TRAMWAYS.

The half-yearly meeting of this Company was held at Newcastle on Monday.

**Lord Armstrong**, who presided, referred to the happy results of the inter-running with the Newcastle Corporation. The delay in giving through traffic facilities on one of the routes arose through difficulties which the Newcastle Corporation were experiencing in the purchase of a house to widen the roadway near the point of junction. On the routes on which through traffic had been begun no hitch, friction, or difficulty of any kind had been experienced. During April—before the running powers were in operation—the number of passengers in Wallsend travelling to or from the junction between the two systems was 28,627, whereas the equivalent figure in September, after through traffic had been introduced, was over 66,000. As the consumption of current was the only item which increased through the additional passengers carried and as their company obtained from the Newcastle Corporation four-fifths of the receipts which the Corporation cars earned on this section of the line, it would be seen that the agreement would far more than justify both the capital cost of securing it and the burden which the efforts in this direction had laid on this year's revenue. Since September the running expenses had been steadily falling, and as a result of a reduction in the rating assessment and the price of current, the total expenses were now below 5½d. per car mile. In the published returns there were only two other tramway companies which showed a lower cost. The receipts had, therefore, exceeded the expenses by a greater amount during the past six months than before.

**Dr. Merz** seconded the adoption of the report, which was carried.

Mr. Summers Hunter and Mr. J. H. B. Noble were re-elected directors, and Mr. Swan, one of the retiring auditors, was re-elected.

Digitized by Google

A dividend was declared out of the profits for the half-year at the rate of 2 per cent. per annum.

At an extraordinary meeting consent was given to the promotion of a Bill in Parliament to enable the Company to issue a portion of their capital as preference shares.

## METROPOLITAN ELECTRIC SUPPLY.

An extraordinary general meeting of this Company was held on Tuesday at Winchester House.

**Mr. W. H. Crippe,** who presided, said the object of the meeting was to conform with the Standing Orders of the House of Commons in respect to their Various Powers Bill and the Acton Bill respectively. Situated west of Willesden was a very considerable area, including Uxbridge, Drayton, and other places, where at the present moment the use of electricity was very little developed. The Company had at Willesden a considerable amount of plant now set free which had been used in supplying St. Marylebone, and it was very desirable as far as possible to find use for it, therefore the Company were applying for powers to serve that district. Another scheme was for the supply of the north-west corner of Paddington, formerly part of Chelsea, which could not be supplied without the consent of Parliament. Further, there was before Parliament the Administrative County of London Bill, which applied for powers to supply not only the whole of London, but practically the whole of Middlesex and a good deal of Kent and Surrey. Their directorate felt very strongly that the present companies in London, which between them had invested many millions of money, were not only in a position, but willing and anxious to supply every scrap of power required for the whole of that district, and in the proposed Bill they sought power to do so. Further clauses in the Bill dealt with the reduction of the capital from £1,000,000 to £750,000. The second Bill was for the supply to Acton.

The meeting unanimously adopted the two Bills.

## SOUTH STAFFORDSHIRE MOND-GAS (POWER AND HEATING).

The report for the year ended Dec. 31 states that the central station has been practically completed, and substantial progress has been made in the laying of the trunk mains, which are also very nearly completed through Bilston to Wolverhampton, and through Wednesbury to Walsall. The latter work would have proceeded more rapidly had it not been that considerable delay has been caused in obtaining the sanction of one of the railway companies to the plans for crossing their lines with the trunk main, and also by negotiations with private owners with whom wayleaves have had to be arranged instead of using the public road on various sections of the trunk main route. The gas plant was started at the end of December, under the supervision of the Company's engineer and the Power-Gas Corporation officials, for the purpose of getting the same into good running order before commencing the supply of gas to customers. Various sections of the plant have been tested, and the whole will shortly be tested under actual working conditions. As far as can be ascertained at present, the subscribed capital of the Company will prove sufficient for the completion and setting to work of the central station and the present distribution scheme.

## ST. JAMES'S AND PALL MALL ELECTRIC LIGHT.

The report for the year ending Dec. 31, 1904, states that the supply has been distributed from the Carnaby-street and Mason's-yard stations of this Company on a total of 278,889 8-c.p. lamps, being an increase of 24,421 in the past 12 months. For this purpose 6,488,589 units were generated at these stations and 2,088,347 were purchased from the Central Electric Supply Company, Limited. The price charged on the supply of the Central Company has been considerably reduced, so that it has not been necessary to draw upon the contingency fund. The Central Company has recently declared a dividend of 5 per cent. on the ordinary shares, in respect of which a sum of £2,500 will in due course be payable to this Company.

| | £ | s. | d. |
|---|---|---|---|
| Net profits applicable to dividend on shares for the year 1904 | 36,146 | 12 | 4 |
| Add balance brought forward from 1903 | 2,744 | 16 | 11 |
| | 38,891 | 9 | 3 |
| Less interim dividend, paid in August last, for half-year ending June 30, at rate of 7 per cent. on preference shares, £3,500; 10 per cent. on ordinary shares, £10,000 | 13,500 | 0 | 0 |
| Leaving an amount now to be dealt with of | £25,391 | 9 | 3 |
| The directors propose to divide this amount as follows: | | | |
| By payment of a dividend of 7 per cent. on the preference shares for the second half-year | £ 3,500 | s. 0 | d. 0 |
| By payment of a dividend on the ordinary shares for the second half-year of 7s. 6d. per share, and a bonus of 2s. per share, making, with the interim dividend paid on Aug. 1 last, a total distribution of 14½ per cent. for the year | 19,000 | 0 | 0 |
| Amount to be carried forward | 2,891 | 9 | 3 |
| | £25,391 | 9 | 3 |

## BLACKPOOL AND FLEETWOOD TRAMROAD.

The report of this Company for the half-year ended Dec. 31 last, to be submitted at the meeting on the 23rd inst. at Manchester, states that, including the sum brought forward from last half-year, the balance of profits, after providing for debenture interest, is £10,714, and the directors recommend a dividend at the rate of 9 per cent. per annum for the half-year, which will absorb £6,750, writing off £1,500 to depreciation reserve and £500 to general reserve account, leaving a balance of £1,964 to be carried forward. The number of passengers carried during the half-year was 1,546,617. The receipts from all sources amounted to £21,699.

## SOUTH WALES ELECTRICAL POWER DISTRIBUTION.

At a Wharncliffe meeting of this Company the solicitor read and explained the provisions of the proposed parliamentary Bill, and the following resolution was unanimously passed: "That the Bill, entitled a Bill to transfer to and vest in the South Wales Electrical Power Distribution Company the undertaking of the Carmarthenshire Electrical Power Company, and for other purposes, be, and the same is, hereby approved subject to such alterations and conditions as Parliament may make and may be approved of by the directors and the company."

## CENTRAL ELECTRIC SUPPLY.

The report for the year ending Dec. 31, 1904, states that energy has been supplied to the St. James's and Pall Mall Electric Light Company, Limited, and the Westminster Electric Supply Corporation, Limited, throughout the year, to an amount of 6,214,873 units. This increase of output has materially affected the costs of production, and for the past year the Company have been able to considerably reduce the charge for supply. A Bill for an extension of the Company's powers will be dealt with in the ensuing session of Parliament. Further debenture stock, amounting to £48,014, has been issued during the year, and the premium on the issue, after deducting the expenses, has been carried to the credit of the capital reserve account.

| | £ | s. | d. |
|---|---|---|---|
| After making a full allowance for sinking fund and depreciation, the net balance for the year 1904 is | 604 | 10 | 1 |
| Add balance brought forward from 1903 | 4,402 | 19 | 11 |
| Leaving an amount now to be dealt with of | £5,007 | 10 | 0 |
| The directors propose to divide this amount as follows: | | | |
| By payment of a dividend at the rate of 5 per cent. on the ordinary shares for the year | 5,000 | 0 | 0 |
| Amount to be carried forward | 7 | 10 | 0 |
| | £5,007 | 10 | 0 |

## LIENS REGISTERED.

**Hastings and District Electric Tramways Company, Limited.** A trust deed, dated Nov. 20, 1904, to secure £250,000 debenture stock, has been registered. Property charged: 35,880 shares in the Hastings Tramways Company and the company's other assets and undertaking, present and future. Trustees: Debenture Securities Investment Company, Limited, 12, Moorgate-street, E.C.

**Havana Electricity Company, Limited.**—A trust deed, dated Jan. 19, 1905, to secure £150,000 debentures, created by resolution of even date, has been registered. Property charged: certain bonds of the La Compañia de Electricidad de Cuba for 1,500,000dol. in United States gold, and the company's undertaking and other assets, present and future. Trustees: H. Rüffer, Menival, Sydenham, and Major W. E. E. Gordon, M.P., 4, Chelsea-embankment, S.W.

**Northwich Electric Supply Company, Limited.**—A trust deed, dated Jan. 12, 1905, to secure £11,000, has been registered. Property charged: the company's freehold and leasehold lands and hereditaments and its undertaking and property, present and future. Trustees: Brunner, Mond, and Co., Limited, Winnington, Northwich.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Milan.**—The Mediterranean Railways require tenders for an electric crane to be erected at Gallarate. Tenders by Feb. 10.

**Arenas De San Pedro.**—The Municipality require tenders for public electric lighting for 20 years. Tenders by Feb. 12.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Bury.**—The Electricity Committee invite tenders for the supply and erection of one 500-kw. direct-current high-speed generating set. Tenders by Feb. 14.

**Swindon.**—The Corporation invite tenders for the supply, delivery, and erection of switch panels, etc. Tenders by Feb. 21. See advertisement in last issue.

**Dublin.**—The Corporation invite tenders for the supply of arc lamp carbons to their electricity undertaking. Tenders by Feb. 23. See advertisement in last issue.

**Lirla.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Battersea.**—The Council require tenders for the supply for one year from March 31 next of electricity meters, joint-boxes, carbons, coal, and oil stoves. Tenders by Feb. 27.

Digitized by Google

**Newport.**—The Visiting (Lunacy) Committee invite tenders for the installation of fire-alarms, telephones, etc., at the county borough asylum. Tenders by Feb. 14. See advertisement in last issue.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Leith.**—The Corporation invite tenders for the supply and erection of one 600-kw. steam dynamo, one water-tube boiler, and one traction switchboard. Tenders to the Town Clerk by 6 p.m. on Feb. 15.

**Manchester.**—The Tramways Committee invite tenders for the supply and erection of a main switchboard, auxiliary distribution boards, etc., for their car-repairing works. Tenders by Feb. 14. See advertisement in last issue.

**Stockton-on-Tees.**—The District Fund, Gas, Quay, and Electricity Committees invite tenders for the several articles and stores required by them for the year ending March 31, 1906. Tenders by Feb. 10. See advertisement in last issue.

**Rathmines and Rathgar.**—The Urban District Council invite tenders for the supply of coal for electric lighting purposes (about 2,000 tons), cables, etc., arc lamp carbons, and general stores. Tenders by Feb. 20. See advertisement.

**Great Western Railway.**—The directors invite tenders for the supply, delivery, and erection of plant in connection with their electricity generating station at Park Royal and proposed sub-stations and distributing centres at various places. Tenders by March 13. See advertisement.

**Kilkenny.**—The Committee of the District Lunatic Asylum invite tenders for fixing in the asylum an electric installation of tell-tales, consisting of 18 stations, and one recording tell-tale clock. Tenders must be delivered at Asylum before 4 p.m. on Feb. 20. Mr. Joseph Brennan, clerk.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Wimbledon.**—The Urban District Council invite tenders for the supply of (3) engine-room stores, (4) cables, (5) joint-boxes and jointing materials, (6) transformers, (7) meters, (8) oils, (9) incandescent electric lamps, carbons, and accessories, (10) iron castings. Tenders by March 4. See advertisement.

**Islington.**—The Council invite tenders for (Section A) meters, (B) time switches, (C) earthenware pipes, (D) carbons, (E) incandescent lamps, (F) terminal boxes, (G) arc lamp globes, (H) oils and lubricants, (I) waste, etc., (J) belting, (K) rubber and asbestos, (L) engineers' stores, sundries. Tenders by Feb. 23. See advertisement.

**Portsmouth.**—The Corporation invite tenders for 12 months' supply of electrical and other stores, laying cables, etc., and for carting coal from steamer to bunkers at the electric lighting station, Portsmouth. Tenders, by Feb. 15, to the Manager, Electric Light Station, Gunwharf-road, Portsmouth, from whom forms of tender can be obtained.

**Batley.**—The Batley Co operative Society, Limited, Commercial-street, Batley, invite tenders for wiring and fittings in connection with the electric light installation at the new central stores. Copies of the specifications can be had on receipt of 10s. at the offices of Mr. Harry B. Buckley, architect, 85, Commercial-street, Batley, up to Feb. 16, and tenders are to be delivered by 4 p.m. on Feb. 20.

**Manchester.**—The Electricity Committee invite tenders for the supply, delivery, and erection of the following at Dickinson-street station and sub-stations: (a) motor-generators, (b) five-wire balancers. Further information will be given by Mr. S. L. Pearce, chief engineer, Electricity Works, Dickinson-street, Manchester. Tenders to the chairman of the Electricity Committee, Town Hall, by 10 a.m. on Feb. 21.

**Stockport.**—The Gas and Electricity Committee invite tenders for the supply, delivery, and erection complete of one 21-kw. tramway rail return booster. Specification, conditions, and form of tender may be obtained from Mr. A. J. H. Carter, borough electrical engineer, Millgate, Stockport. Tenders, addressed to the Chairman of the Gas and Electricity Committee, Town Clerk's Office, Stockport, by noon on Feb. 15.

**Bournemouth.**—The Town Council invite tenders for the following: Contract No. 1 (Section A) steel grooved girder rails, etc.; (B) permanent-way construction and rail bonding; (C) wood blocks and granite sett edging. Further particulars and drawings, etc., may be obtained at the office of the engineer, Mr. F. W. Lacey, M.I.C.E., Municipal Offices, Bournemouth. Tenders to the town clerk, Mr. Geo. Wm. Bailey, by 10 a.m. on Feb. 15.

**Fulham.**—The Borough Council invite tenders for the supply and erection of (A) condensing plant; (B) boilers; (C) economisers; (D) stokers. Specification, drawings, and form of tender may be obtained from the borough electrical and consulting engineer, Mr. Arthur J. Fuller, on payment of a deposit of £1. 1s., which will be returned on receipt of a bona fide tender. Tender to the Town Clerk by 12 noon on Feb. 22. See advertisement in last issue.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A *pro forma* contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**South Shields.**—The Electricity Supply Department invite tenders for the supply, delivery, and erection of the following plant: (Contract No. 67) one multitubular marine-type boiler, with chimney and mountings; (68) two medium-speed open-type vertical engines for two 550-kw. direct-current traction generators; (69) two 550-kw. direct-current traction generators; (70) traction switchboard; tramways department—(Contract No. 4) electric tramcars, complete with "Brill" trucks, for the Corporation. Copies of specifications, conditions, form of tender, also form of contract, can now be obtained from Mr. J. H. Cawthra, M.I.E.E., borough electrical engineer, South Shields, on payment of £2. 2s. for each contract, which sum will be returned on receipt of a bona fide tender for each contract. Tenders to Mr. J. Moore Hayton, town clerk, Court-buildings, South Shields, by noon on March 13.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consulting Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess, M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

## RESULTS OF TENDERS.

**Middleton.**—The Corporation have accepted the tender of Meldrum Bros., Temperley, Manchester, for a dust destructor; the tender of W. B. Haigh and Co., Limited, Oldham, for the superheater; and that of Tetlow Bros., Hollinwood, Oldham, for boiler at the electricity station.

**Battersea.**—The Council have accepted the tender of C. A. Parsons and Co., at £4,680, to supply and fix one 750-kw. turbo-generator set at the central electric generating station; and the offer of Green and Sons, at £494. 17s., to supply and erect at the central electric generating station a special fuel economiser, consisting of 256 tubes.

**Sydney.**—The City Council have accepted the tender of Henley's Telegraph Works Company for the making of house connections and the laying of electric light cables for six months at the following rates: (A) services under footways up to 5ft. trench length, £2. 3s.; from 5ft. to 10ft., £2. 10s.; 10ft. to 20ft., £3. 1s. (B) under roadways, ordinary paving, £3. 9s.; block paving, £5. 17s. 6d.

**Transformers.**—The Islington Borough Council have placed an order for seven 30-kw. single-phase transformers with Messrs. Ferranti Limited. Messrs. Ferranti have also received orders recently for three-phase and single-phase transformers from the Midland Electric Corporation for Power Distribution, Limited (10 boosters); Bloemfontein Corporation, Eccles Corporation, and Messrs. Bruce Peebles and Co., Limited, etc.

# BUSINESS NOTES.

## TRACTION.

**Rochdale.**—The Corporation traffic returns for Jan. 7 totalled £1,718 against £1,755 last year.

**Halifax.**—The Corporation have decided to proceed with the scheme of tramway extensions, but those outside the borough have been deleted.

**Birkenhead.**—A conference between the respective committees of the Corporation is to be held in regard to running cars or motor 'buses to the ferries.

**Perth.**—It is reported that the plans for the reconstruction of the permanent way have had to be varied, owing to the location of water and other pipes.

**Swansea.**—At last week's meeting of the Tramway Committee it was reported that the new track would probably be completed by the end of the month.

**Grimsby.**—The Light Railway Commissioners have sanctioned the scheme for a line to the new Immingham Dock, of which we gave particulars recently.

**Derby.**—The question of proceeding with the route from Market-place to the borough boundary has been referred back to committee for further particulars as to cost.

Digitized by Google

**Keighley.**—The Stockbridge extension is practically complete, and may be opened to-day. A proposal to institute ½d. fares has been referred to committee for a report on the subject.

**Glasgow.**—It is reported that the opposition by the Pollokshaws Town Council to the Corporation tramway provisional order for extending their system will be withdrawn, terms having been agreed upon.

**The Monorail System.**—A working model of the Kearney-Thom electric monorail system, which is to be used on the proposed London and Sussex Railway, was exhibited last week at the exhibition held at the Battersea Town Hall.

**Blackburn.**—The Corporation tramway returns for the nine months ending Dec. 31 show considerable improvement, although there is still an adverse balance. This, however, has been reduced to £601 against £2.144 for the corresponding period of the previous year.

**Western Wagon Property Co.**—For the year ending Dec. 31 this company shows a net revenue of £17,546. A further dividend of £6,650, making 10 per annum, is to be paid, leaving £899 to be written off for old stock, and a sum of £670, which has been carried forward.

**Tipton.**—It is reported that the solicitor to the Council having had an abortive interview with Mr. J. A. Lycett, it has been decided to proceed with the action to compel the tramway company to carry out its obligation to electrically equip the line from Dudley to Wednesbury.

**Stockport.**—The Corporation and the Ashton, Oldham, and Hyde Tramway Company have agreed to compare figures in order to arrive at a fresh agreement regarding through running between Hyde and Bredbury, the company contending that the present arrangement is unfair to them.

**Underground Electric Railways Co.**—It is reported from New York that the profit-sharing notes of the Underground Electric Railways of London underwritten by Messrs. Speyer Bros.' syndicate have all been disposed of to the public and various financial institutions, and the syndicate is now dissolved.

**Batley.**—The Corporation have decided to oppose the Dewsbury Tramway Company's application for an extension of license for 12 months to use steam power on the Bradford-road pending reconstruction. The Corporation are prepared to assent to a six months' extension. The Birkenshaw Council are also opposing.

**Hastings.**—A letter in somewhat conciliatory terms, but adhering to the overhead system for the front, from the solicitors to the promoters was read at last week's meeting of the Corporation. The opposition to the company's Bill is, however, to be continued, though Councillor Boutwood reiterated his plea for a compromise.

**Railway Bills.**—The Great Northern, Piccadilly, and Brompton Railway (No. 2), which was opposed by the Marquis of Salisbury and Sir Walter Phillimore, has complied with Standing Orders. The Hammersmith, City, and North-East London Railway Bill has been referred by the examiner to the Standing Orders Committee, certain formalities not having been complied with.

**Manchester.**—The Tramways Committee have adopted a scale of charges for parcels, fixing "inside" and "outside" rates for the city and its environs respectively. They also decided to run motor 'buses to Cheadle, Northenden, and Chorlton-cum-Hardy. At present horsed omnibuses are run to each of these places, meeting the tramcars at convenient points, and these conveyances are much used, especially in summer.

**Bradford.**—On Wednesday evening a car failed to grip the rails on the Barkerend-road incline, owing to the greasy state of the line, and started to go backwards, although the driver checked the pace by the application of the brakes. Finally it was stopped through colliding with a car bound for the same point. Though the impact was considerable, no injuries were sustained by the passengers beyond a shock, except in the case of two ladies who jumped off.

**Great Northern, Piccadilly, and Brompton Railway Co.**—The capital expenditure during the half-year amounted to £644,896. The estimate for the current half-year is £750,000. The progress of the works during the past half year has been satisfactory. The rent due from the Underground Electric Railways Company of London, Limited, under the terms of the agreement for lease dated Jan. 13, 1903, up to Dec. 31, 1004, permits of a dividend at the rate of 4 per cent. per annum.

**North-Eastern Railway.**—The half yearly report states that during the period under review the company have carried on the Newcastle and Tynemouth suburban lines which are now worked by electricity, 675,000 more passengers between stations on these branches than in the corresponding half of 1903. The directors consider that the results of substituting electricity for steam in working the passenger traffic on these lines have, so far, been satisfactory as regards receipts and expenses.

**Maidstone.**—An enquiry has been held into the application of the Town Council for leave to borrow £60,000 for extending the light railway service. Two new routes are proposed, one from the top of High-street, down Gabriel's-hill, as far as the King's Arms, Loose, and the other from the top of High-street, along Week-street, to Perenden Heath, with a branch along Bexley-road to Holland-road. The Commissioners subsequently inspected the routes, and intimated that a decision would be arrived at shortly.

**Port Elizabeth.**—It is reported that considerable extensions of the tramway network of the Cape Electric Tramways, Limited, are under the consideration of the directors, in addition to which the same company have a Bill before the Cape Parliament for an extension of their Cape Town network into the suburban districts of Woodstock and Maitland. Both schemes will involve large purchases of permanent-way material, while the Cape Town extension will also include the acquisition of rolling-stock and, possibly, sub-station equipment.

**Lancashire and Yorkshire Railway Co.**—At the half-yearly meeting of this company the Chairman, speaking with regard to the Liverpool and Southport line, said that the company could not at present tell the precise cost of working in comparison with steam traction, but reliable accounts were being kept, which would enable this to be done in due course. The increase in the traffic had far exceeded their most sanguine expectations. In the month of December alone, when the dense fogs occurred, they had an increase of 104,000 passengers on that section.

**Highgate-Barnet.**—The electric tramway from Highgate Archway to Barnet, passing through Finchley and Whetstone, is now nearing completion. The rails have been laid for some little time, and the standards to support the wires which will convey the electric current have now been erected. It is hoped that an efficient service of cars may be ready within a few weeks. The short connecting link between the existing horse tramways from the City and Euston to the Archway Tavern and the commencement of the new electric line at the Highgate Archway is not yet sanctioned.

**London County Council.**—The City Corporation have decided to oppose the Council's Embankment scheme, to which we refer in another column. The receipts for the week ending Jan. 28 amounted to £12.048. as against £8,848 last year, and from April 1 the total was £550,061, against £427,754. An enquiry was held last week by the Light Railway Commissioners into the proposal of the County Council to expend an estimated sum of about £250,000 on an extension of the county of Middlesex light railways and tramways in the urban district of Enfield. At the close of the enquiry the Commissioners stated that they would report favourably to the Board of Trade.

**Exeter.**—The Tramways Committee considered on Monday a report on the question of Sunday traffic from the chief officer, who calculated that Sunday traffic would represent at least £780. The committee decided to recommend that the cars be run on the Council's system on Sunday afternoons and evenings from 1.30 to 10. As a result of a conference between the Electric Lighting and Tramway Committees, it is recommended that the price to be charged for electric current to the tramways undertaking be 1¼d. per unit for the first 100,000 units, and 1½d. per unit for any amount taken after the first 100,000; also, that the electrical engineer have charge of the overhead work and the electrical apparatus on the tramway system and in the depôt.

**West Cumberland.**—At a meeting of representatives of the Whitehaven Town Council, Workington Town Council, Maryport Urban Council, and Cleator Moor District Council a letter was considered from the solicitors for the West Cumberland Tramways Company. The letter stated that the engineers of the company (Sir Douglas Fox and Partners) have completed detailed specifications and bills of quantities, and tenders have been received from the Brush Electrical Engineering Company, Limited, and other contractors for carrying out the work. A prospectus inviting public subscriptions will very shortly be issued. After full discussion it was decided to inform the promoters that assent could not be given unless the extension of two years for the commencement of work specified in Clause 3 of the Bill were altered to one year.

**Mansfield and Newark Tramways.**—The delay which has taken place in the commencement of the work of laying down the tramways for which a private company obtained an order in 1901 was the subject of some important and rather strong remarks on Monday at the Notts County Council meeting. At Newark it is proposed to connect the town with the outlying villages of Farndon and Balderton, while the Mansfield scheme is for an extension of the lines and railway sanctioned by the order of 1901. The County Council instructed counsel to represent them at the enquiries to be held by the Light Railway Commissioners, the first of which was held at Newark on Wednesday. The Newark Urban District Council also decided to engage counsel, and to apply for the insertion of clauses relating to widening of streets, term of years for completion, motor power to be used, and terms of purchase.

**Birmingham.**—The Executive Committee of the City Association have prepared a further report upon the tramway scheme of the Birmingham City Council relative to the mode of traction to be adopted. During the last month a demonstration was given in the city at the request of the City Association of the Dolter surface-contact system, and representatives of the association have also inspected the working models of the Waggott surface-contact system. The committee is now completing arrangements with the Lorain Steel Company to take a special party over to Wolverhampton to inspect the whole of the Lorain system of tramways. Shortly afterwards it is hoped to make arrangements for parties to inspect models of the Kingsland surface-contact system and the Waggott surface-contact system. At Tuesday's meeting of the Corporation the agreement with the City of Birmingham Tramways Company in reference to the Balsall Heath route, of which we gave particulars last week, was unanimously confirmed.

**Nottingham.**—The Corporation have considered the Tramway Committee's report as to the Midland Railway Bill, which contains a clause providing for the use by the company of a street service in any district affected by their system. In their report the committee said that the effect of this clause would be to enable the Midland Railway Company to compete with the tramway undertaking of this city. The committee had no desire to oppose a fair system of omnibuses, etc., used only in connection with an extension of the present system of the company, but it appeared to them that the clause went beyond this. The committee were in negotiation with the Midland Railway Company on the matter, and it was hoped that the clause would be modified without going to the expense of opposing the Bill in Parliament. In the meantime, however, it would be necessary to petition against the Bill, and the committee recommended that the Council should direct this to be done. The report was adopted.

Digitized by Google

**Sunderland.**—At a meeting of the Tramways Committee, Mr. A. R. Dayson, manager, reported as to the proceedings of the Executive Committee of the Municipal Tramways Association relative to the Bill which railway companies are promoting in Parliament to have power given them to run omnibuses and conveyances in any area to which their lines run. The committee considered that if this Bill became law, it would place too much power in the railway companies' hands, and they therefore decided to call together a full meeting of the association to discuss the matter. The desirability for a loop in West Wear-street was again considered, and it was decided that the matter should stand over for the present. The returns for January, together with the figures for the corresponding period of 1904, are as follows: passengers, 1,170,675 against 1,113,533, being an increase of 37,142; mileage, 123,183 against 118,442, being an increase of 4,741; and receipts, £4,864 against £4,711—an increase of £153. The receipts per car mile amounted to 9½d. in both cases.

**Leith.**—A start was made on Monday with the reconstruction of the tramways. The first section to be electrified is the new line along Pilrig-street and Newhaven-road to Bonnington, and the continuation of that line along the old horse-car line to Newhaven. The whole work of reconstruction will be carried out with the minimum of inconvenience to the public. A gang of men will commence operations at Pilrig and another at Newhaven. The two gangs will meet about Bonnington, and thus complete the line of rails between the two starting points. The section from the foot of Leith Walk to Pilrig does not require relaying, as the rails there are already bonded for electricity, and it is likely that as soon as the car depôt is ready electric cars will be put on this route from the foot of Leith Walk to Newhaven by way of Pilrig, there being at present sufficient plant at the electric station to provide power during the summer load for the propulsion of a number of cars. It is expected that the extension of the electric station and the additions to the plant will be completed before the next winter load is required.

**North Lincolnshire.**—Two light railway schemes, which would open up a portion of the Isle of Axholme and an important section of North Lincolnshire, were the subject of an enquiry by the Light Railway Commissioners on Tuesday. The first scheme is an extension of the Axholme Light Railway, which was opened to develop the peat moss industry, which is already a great factor in the industrial life of Hatfield, Thorne, and Crowle. The necessity of extending the line to Hatfield has forced itself on the attention of the North-Eastern and Lancashire and Yorkshire Railway Companies, by whom it is worked. The other scheme is known as the Blyton and Frodingham Light Railway, and is to be run from Blyton to within two miles of Frodingham Station, where it will join the Great Central Railway, and be worked by them, the cost of this undertaking being £84,661. The Commissioners thought an order might be granted in the first case. Regarding the Frodingham scheme, the chairman said that the Commissioners were prepared to recommend the Board of Trade to grant an order. They had made a note of the various matters brought before them, some of which might require some settlement. As to a bridge at Blyton, the Commissioners thought a level crossing would be sufficient to meet the case at present. As to cattle guards, the Commissioners would specify such roads as they thought required gates, and others that should have cattle guards.

**Metropolitan District Railway.**—The report contains the following passage: "The work of electrification is nearing completion. The directors are assured by their engineers that within two months the whole of the works necessary to operate the railway electrically will be finished. The various electric railway services will then be commenced as rapidly as the car contractors deliver the cars. The important widening of the company's railway between West Kensington and Hammersmith is nearly finished. A new station is being built, and will shortly be opened, at Barons Court. By arrangement with the Metropolitan Company, the High-street, Kensington, Station, is being rebuilt and enlarged. The company's car-shed and depôt at Ealing Common is finished. Extensive sidings are being laid down at Mill Hill Park, at Gloucester-road, and at Parson's Green. The Harrow and Uxbridge Railway has been opened for traffic. The directors have not thought it wise at present to exercise the running powers to which the company is entitled. The directors have given notice, on behalf of the company, of a Bill enabling the company to apply to the general purposes of the company a portion of the capital authorised by the company's Act of 1897 which is not required for the construction of the deep-level railway. Several important schemes will be submitted to Parliament adversely affecting the company. In view of the early adoption of electric traction, and the entire abolition of steam traffic upon the railway, and the changes which will be involved, the directors have made several important alterations in the company's staff."

**Newcastle.**—At the meeting of the Tramways Committee the acting general manager (Mr. T. P. Easton) presented a report relative to the estimates of working for the year ending March 31, 1906. The estimates do not include the amount necessary for the maintenance of the track or the amount necessary for the payment of interest and redemption. Mr. Easton bases his calculations upon the present cost of working—*i.e.*, 6¾d. per car mile—which he acknowledges to be a high rate as compared with other large towns, notwithstanding the economies which have been effected. The average traffic receipts for 45 weeks of the present year equal £3,660 per week, and Mr. Easton estimates the receipts for the ensuing year at £194,737, including amounts payable by the Lighting Committee. The expenses are estimated at £115,265, leaving a balance available of £79,472. The sum of £10,131, representing the estimated expenditure prepared by the city engineer (Mr. Edge) in his report for repairs and renewals to the tramway track, must, however, be added to the estimated expenses referred to above—namely, £115,265—thus making a total of £125,396. This will reduce the balance to £69,341, out of which must be paid the sum of £67,142, being the city treasurer's estimate for the amount necessary for the payment of interest and redemption. This will further reduce the balance to £2,199. The total amount estimated for maintenance work, including the city engineer's estimate for track repairs, amounts to £32,958. A long conversation ensued regarding the estimates, and ultimately it was decided to adopt them, along with the suggestion of the city engineer and the estimate prepared by the city treasurer. The subject will in due course be brought before a meeting of the City Council.

## LIGHTING AND GENERAL.

**London County Council.**—On Tuesday the Hampstead Borough Council received sanction to the borrowing of £4,335 for electric lighting purposes.

**Longton.**—The output of electricity at the Town Council's works during the month was 13,220 units, being an increase as compared with last year of 7 per cent.

**New Issue.**—The Electric Conversion Syndicate, Limited, are issuing 85,000 of the preference shares of the Durham Collieries Electric Power Company.

**South Metropolitan Electric Light and Power Co.**—The preference share register of this company will be closed as from the 15th to the 28th inst. inclusive.

**London Gazette.**—A first and final dividend of 3s. 6d. in the £ has been declared in the estate of Benjamin George Hedges, electrical engineer, 20, St. Luke's-street, Derby.

**St. Andrews.**—Four arc lamps are to be erected in a central position as an experiment in street-lighting. Mr. H. Richardson, electrical engineer, Dundee, is to be consulted in the matter.

**Loughborough.**—The engineer has been asked to make enquiries for manufacturers as to the cost, etc., in connection with his suggestion to letting motors and arc lamps on hire to consumers.

**Huntingdon.**—The Town Council have an application for the provisional order for electric light in the borough, and have asked Mr. Waudle Stephens, of Stamford, to enquire into the matter and report thereon.

**Electrical Exhibition.**—Particulars of the County of London Electric Supply Company's electrical exhibition to be held at 118 to 122, Holborn, E.C., from March 20 to April 5 appear in another column.

**Telegraph Construction and Maintenance Co.**—The directors propose to pay a dividend of 10 per cent. (£1. 4s. per share) in addition to the 5 per cent. already paid, making 15 per cent. for the year 1904.

**Award.**—We learn that Messrs. Brown Bros., Limited, 22-30, Great Eastern-street, E.C., have obtained for their Brown motorcar a silver medal for elegancy over 85 competitors at the Turin Motor Exhibition.

**St. James's and Pall Mall Electric Light Co.**—The share transfer books of the company will be closed from Feb. 8 to 22, both days inclusive, preparatory to the payment of dividends for the half-year ended Dec. 31 last.

**Chelsea Electric Supply Co.**—The directors have decided to recommend, subject to audit, a dividend on the ordinary shares at the rate of 7½ per cent. per annum for the half-year to Dec. 31, 1904, making 6 per cent. for the year, carrying forward about £1,170.

**Wakefield.**—The City Council propose to apply for sanction to borrow a further sum of £18 000 for the purposes of extensions in connection with the electrical undertaking. The appointment of a city electrical engineer in succession to Mr. Shaw has not yet been made.

**Birkenhead.**—The steady increase in the use of electricity in Birkenhead is maintained. The Electricity Committee in their last report show that during the past quarter 272 555 units were consumed by 717 customers, being an increase of 30 335 units and 149 consumers.

**Smithfield Markets Electric Supply Co.**—The directors propose to place £1,500 to the general reserve fund, raising it to £5,740; to add £1,000 to the depreciation fund; and to pay a dividend at the rate of 4 per cent. for the year; carrying forward a sum of £1,659.

**Swansea Telephones.**—There are now 980 subscribers' lines in operation, and 173 orders in hand. Preparations are being made with reference to the proposed action to compel the National Company to grant inter-communication. Once the legal matters had been settled the case would be put down for trial.

**Horsham.**—The Urban District Council have decided to apply for sanction to borrow £4 500 for electric lighting purposes. This amount includes £500 for free wiring purposes and £1,000 for the cost of various extensions which have been already carried out, but which were not included in the previous scheme.

**Kensington and Knightsbridge Electric Lighting Co.**—The directors recommend a dividend on the ordinary shares at the rate of 10 per cent. per annum for the half-year ending Dec. 31, 1904, and a bonus of 2 per cent. for the year, making with the interim dividend paid on Aug. 1 12 per cent. for the year 1904.

**Bishop's Stortford.**—Copies of the objections made by the Bishop's Stortford and District Gas Company to the Council's application for an electric lighting order were laid before the Urban District Council at the last meeting, and it was decided to leave the matter to be settled by their parliamentary agent.

**Electrical Trades Union.**—At a meeting of the Electrical Trades Union, at Aston, on Feb. 2 a resolution was passed recording the meeting's emphatic disapproval and condemnation of the employment of cheap labour upon the electrification of the London railways, considering it a possible source of very grave danger to the travelling public.

**London Branch.**—Messrs. John M. Henderson and Co., of King-street Engineering Works, Aberdeen, have established an office at

Digitized by Google

26, Victoria-street, S.W., where, we are informed, an engineer or representative will be available at all times for the transaction of urgent and other business in London and district. The registered address for London telegrams is "Cableways"; telephone No. 431 Victoria.

**National Telephone Co.**—After paying the dividend on the preferred ordinary stock, a distribution at the rate of 5 per cent. per annum for the half-year ended Dec. 31 is declared on the deferred ordinary stock. The sum of £115,000 is placed to reserve and about £10,000 is carried forward. A year ago the dividend was at the same rate, £110,000 was placed to reserve, and £10,500 carried forward.

**Electric Lamp Tests.**—In connection with the independent tests just concluded by the Westminster Electric Testing Laboratory, of York-street, Westminster, we are asked to mention that the A.E.G. make (Electrical Company, Limited), which is a foreign one, comes out almost as well as the best English make, and infinitely better than the average make of the various manufacturers. The company also think that the difference in price should be taken into account when ordering such goods.

**Gravesend.**—At the adjourned meeting of the Gravesend and Northfleet Tradesmen's Association last week the proposition of Mr. Harrington of the previous week—viz., "That in the opinion of this meeting the proposal of the Gravesend Town Council to apply to the Board of Trade for powers to supply Northfleet without the consent of its District Council is inadvisable, and, while certain to involve the borough in heavy law costs, is without a reasonable possibility of success"—was carried.

**Willesden Polytechnic Electrical Engineering Society.**—On Saturday last the third annual dinner of the society was held at the Horseshoe Hotel, under the chairmanship of Mr. Frederic H. Taylor, A.M.I.E.E. At the conclusion of the dinner programme the annual report of the secretary, Mr. H. Drury, was read, and this showed the most successful year the society had known. Many new members have recently been elected, and a lending library for technical works is now being organised by the committee.

**Dance.**—Messrs. Anderson and Munro, electrical engineers, Glasgow and Edinburgh, held their annual gathering and dance in the Masonic-chambers, Glasgow, on Friday last. There was a large company of employés and friends present, and many of the country foremen sent their good wishes for a happy evening. We are glad, in face of the many grumblers who made themselves heard recently, to note that it was remarked that not during the whole 65 years of the firm's existence had there been one so satisfactory in every respect as 1904.

**Derby.**—The Electric Lighting Committee in their report mention the following extras on the undermentioned contracts, and also the amount of architect's commission—viz.: new battery-house contract (Messrs. Radford and Greaves), £24. 15s. 10d.; switchboard platform contract (Mr. H. Vernon), £9. 4s.; turbine bed contract (Mr. E. Morley), £87. 14s. 3d.; architect's commission (Mr. A. Eaton), £163. 6s.—total, £285. 0s. 1d. The above amount of £285. 0s. 1d. is included in the sum of £33,400 granted by the Council in May, 1903.

**Stoke Newington.**—A special meeting of the Council will be held to-night, in pursuance of a requisition, for the following purpose—viz: to consider the desirability of opposing in Parliament the London Building Acts Amendment Bill and the Bills of the Administrative County of London and District Electric Power Company and the Charing Cross and Strand Electricity Supply Corporation (Power Supply), and if thought desirable, to seal petitions in opposition thereto, and to give such directions in connection therewith as the Council may think fit.

**Municipal Telephones.**—The official figures of the National Telephone Company, just issued, show the progress of municipal telephones in 1904. The relative increase in the number of stations or working instruments for the year ended Dec. 31 is as follows: Glasgow—Corporation increase 1,504, National 5,209; Portsmouth—Corporation 553, National increase 981; Swansea—National increase 702; Corporation 488. The grand totals at Glasgow are: National, 17,227; Corporation, 12,136. The totals at Swansea are: National, 2,548; municipal, 1,067.

**Bo'ness.**—The installation of electricity for the lighting of Bo'ness was inaugurated on Feb. 6. The works, which are estimated to cost about £25,000, have been constructed by the National Electric Construction Company, which have already fitted installations in Oban, Musselburgh, and other towns. The power station is situated in the centre of the burgh, near the docks, and cables have been laid throughout the burgh. The light has been running for some months by means of a temporary engine for the lighting of the new library, town hall, and infectious diseases hospital.

**St. Annes.**—Mr. J. H. Clothier, electrical engineer, in his last report, gives the following figures: units sold during December, 51,919; units sold to Dec. 31, 459,820; equivalent to 8-c.p. lamps connected, 16,300; units sold per 8-c.p. lamp connected, 9·5; maximum load, lighting, 173·7 kw.; ditto, traction, 100 kw.; total number of consumers, 305. They had also received three applications for an addition of 100 8-c.p. lamps. Mr. Clothier says that the small total increase for the month is due to a decreased demand by the tramway company, and that the private lighting shows the substantial increase of about 30 per cent.

**Stepney.**—The Borough Council have agreed to order an additional steam-turbine generator from Messrs. Parsons and Co., Newcastle-on-Tyne, at £5,900, being about £877 less than the amount of their previous tender. This reduction is largely due to the fact that a spare armature was supplied with the turbine already delivered. The cost of providing the plant has been included in the estimate of £78,280 approved by the Council on Jan. 6, 1904, in respect of the extension of the system. The Council have also decided to borrow £3,700 for providing further storage tanks, water-softening plant, artesian well, pipes, and pumps at the electric lighting station.

**X-Rays.**—Mr. and Mrs. W. K. Vanderbilt have, it is said, after a successful cure of rheumatism by X-rays, founded and endowed a hospital in the Rue Leonard de Vinci, Paris, at a cost of £40,000. The building, which will be a model institution for treatment by the latest scientific methods and appliances, is practically complete. On the ground floor are the laboratories for the preparation of serum of various kinds and for other services. On the first floor are eight rooms, with 10 beds each. The hospital will be supported entirely by the founders, and the patients will be treated absolutely free of cost. The institution has been placed under the direction of Dr. Georges Gautier.

**Sydney (N.S.W.).**—Mr. Sidney Smith, the Postmaster-General of the Australian Commonwealth, is about to promote the extensive use of telegraph wires for telephone purposes. A test has recently been made in this direction on the line between Geelong and Barwen Heads, thus connecting the latter direct with Melbourne. The first official estimate of the cost of this connection was £400. It was then reduced to £252. Both estimates were conditional upon a payment of £168 by the residents. The distance between the two points is 15 miles. By the utilisation of the telegraph wires the whole work has now been completed at a cost of £5, while the residents will not be asked to contribute one penny.

**Edinburgh.**—The Town Council have adopted a suggestion by Mr. Stevenson, convener of the Electric Lighting Committee, to authorise the committee to undertake the testing of incandescent lamps for use in the city at a charge of 6d. per dozen. He explained that a large number of uneconomical lamps was being used in the city, and thus injustice was being done to the consumers. It was therefore proposed to set up a testing plant where wiring contractors could have their lamps tested and stamped, so that consumers might be satisfied that they were getting lamps sufficient to consume the current for which they were paying. The stamping would be optional. The committee has been empowered to proceed with the painting of the power stations at Dewar-place and M'Donald-road at an estimated cost of £700.

**Stock Exchange.**—The Stock Exchange Committee have appointed Feb. 15 special settling day for Bath Electric Tramways Company's £135,000 4½ per cent. first mortgage debenture stock. The committee have also ordered the undermentioned securities to be quoted in the official list: Bath Electric Tramways Company's £135,000 4½ per cent. first mortgage debenture stock; Birmingham and Midland Tramways, Limited, £200,000 4½ per cent. first debenture stock, redeemable. The committee have been asked to appoint a special settling day in Marconi's Wireless Telegraph Company's further issue of 30,016 shares of £1 each, fully paid, Nos. 196,112 to 196,127 and 221,128 to 251,127; and to allow to be quoted in the official list City of Buenos Ayres Tramways Company's (1904) 248,000 shares of £5 each, fully paid, Nos. 1 to 248,000; and £174,000 4 per cent. debenture stock, in lieu of the shares and debenture stock of the City of Buenos Ayres Tramways Company now quoted.

**Battersea.**—The Council have been in communication with the London and South-Western Railway Company for some time past with reference to the supply of electrical energy for the purpose of their electric installation, particularly for the lighting and supply of power at the Nine Elms goods yard. The company have now stated their willingness to take a supply of electrical energy in the first instance for any purpose on their railway from points in Plough-road, Clapham Junction, Nine Elms, and New-road, and guarantee a consumption for five years of 200,000 units per annum, as per terms agreed upon. The company may at a later date require a much larger quantity to be supplied. The electrical engineer is to prepare a scheme for the lighting by electricity of Nine Elms ward, including provision for the supply of electrical energy to the Nine Elms goods yard of the London and South-Western Railway. In the meantime, however, to cope with the present demand of the company and as a matter of urgency, six double tariff meters are to be procured of the General Electrical Company at a cost of £78.

**Marconi's Wireless Telegraph Co.**—The directors in their annual report, to be presented at the annual ordinary general meeting of the company on Feb. 16, gives some interesting details of the work carried on at their various stations. They consider that as a result of Mr. Marconi's experiments the company is now in possession of all the data necessary for the equipment of stations for good commercial working between England and the continent of America, and a new station embodying the latest improvements equipped on a commercial scale is already nearly completed in Canada. The question of a site for a new station in Great Britain, for which the greater part of the machinery has already been ordered, is still under consideration. Reckoning the total number of words transmitted per year at the rate of only 15 words a minute, for 10 hours a day for 300 days, it is estimated that two wireless stations should earn, after deducting land charges, about £56,000 per annum. The stations already equipped at Poldhu, Cornwall, and Cape Cod, Massachusetts, are being regularly employed for transmission of messages to ships fitted with long-distance receiving apparatus at any point on the Atlantic, and by the results of the working of these stations during the last seven months, the directors are confirmed in their belief that the new stations will afford a satisfactory service between England and the continent of America. Reference is made to the company's agreement with the Post Office, War Office, and Admiralty, and details are given of the company's stations which have been equipped in Canada, Newfoundland, Italy, Holland, and Chili, showing that the company are making satisfactory progress in all parts of the world. The accounts for the year ended Sept. 30, 1904, show an increased profit on the year's working, the net profit for the year ending Sept. 30, 1904, being £12,681. 5s. 3d., as against £10,607. 7s. 8d. for the year ending Sept. 30, 1903. Full particulars of the report and accounts are given in another column.

Digitized by Google

**Electrical Exhibition.**—A two weeks' electrical exhibition will be held next month in the new department of Messrs. R. Stephens and Sons' foundry, top of Tucking-mill-hill, by Edmundson's Electric Company, the owners of the Camborne-Redruth electric works. We understand that the company have two travelling exhibitions, one in the North and the other now travelling in Cornwall. The proceeds of this exhibition will be handed to the Miners' Hospital, and Messrs. Stephens and Son have offered to give half of the sum they will receive by way of rent to the Miners' Hospital as well. Concerts and other attractions are being arranged.

**Feed-Water Purifiers.**—The Paterson Engineering Company, Limited, Amberley House, Norfolk-street, W.C., report the following orders recently executed and received by them for Paterson feed-water purifiers for power plants: Babcock and Wilcox, Limited, for H.M. Dockyards, Pembroke, and Gosport and Fareham tramways; Belliss and Morcom, Limited, for their Ledsam-street works; Danks and Co., for H.M. Dockyards, Chatham; Electric Construction Company (two) for H.M. Dockyards, Gibraltar; Mirrlees-Watson Company, for Partick Electricity Works; Crompton and Co., for Ultadunga Station, Calcutta; Earl of Rosslyn's Collieries Company, Limited; Sharp and Sons, Baltic Sawmills, Dartford; Busbridge and Co, paper makers, Kent; and other private firms.

**Dublin.**—The Council have adopted a report of the committee of the whole house upon the reports, etc., in connection with the electric lighting scheme, recommending the Council to retain control over the electric lighting undertaking and the working thereof; also that the committee undertake no further or additional construction works until the consulting engineer has reported that the works covered by his agreement with the Corporation of Sept. 22, 1899, have been finally completed, provided that the Lighting Committee be at liberty to carry out all necessary services' work in connection with the giving of supplies to new consumers, and the extending of the existing distributing mains where necessary within the present area of supply, and where there is statutory obligation to give such supply.

**Football.**—On Feb. 1 a return match was played on the ground of the Reading Football Club, at Elm Park, between the Reading Corporation Tramways and the London United Tramways. There was a good attendance of the public, together with many members of the Corporation, and a well-contested game ended in a win for the Reading men by six goals to nil. Unfortunately, the goalkeeper of the Londoners met with an accident, fracturing his kneecap and necessitating his being taken to the hospital and a substitute put in his place. In the evening both teams were entertained by Mr. Councillor Bull, chairman of the Tramways Committee, and a very successful smoking concert concluded the evening. The above is the fourth match played with the London United Tramways Company, each club previously winning games on their own ground by three goals to two.

**Stretford.**—The additional plant recently installed at the Council station will give the necessary current for electric lighting extensions and for the proposed tramway to Chorlton-cum-Hardy. A large number of houses in the district have already been wired, and a provisional arrangement has been entered into between the Trafford Park Electric Power Company and the District Council of Stretford, by which the electric lighting in the residential portion of Trafford Park is now undertaken by the local authority. Provision has also been made to supply the southern tramway extension to Urmston whenever it comes into operation. The total cost of the additional plant is £6,500, and the Council's installation down to date has cost £42,000. The Electricity Committee have finally recommended the Council to reduce the charge for electric light to private consumers from 6d. to 4½d. per unit.

**Glossop.**—The Guardians have been considering what it would cost to fit up the workhouse buildings with electric light. It appears that for the workhouse proper there would be required 49 8-c.p. lamps, 29 16-c.p. lamps, and 83 switches. For this portion of the work the cost would be £75. 6s. For the tramp ward five lights would be required, and the cost would be £5. 2s. For the infirmary they wanted 32 8-c.p. and 27 16-c.p. lamps, two pulley fittings, 59 switches, etc., the cost of which would be £50. Owing to the distance of the buildings from the nearest underground cable, the Urban Electric Supply Company, Limited, ask the Board to pay a rental of 22s. per quarter for the portion of the underground cable required. The total amount of the estimate for the work is £130. 12s. The question of the desirability of installing the electric light or otherwise has been left in the hands of a committee, consisting of Messrs. Furniss, Rowbottom, Hyde, T. Waterhouse, S. Gregory, J. Malkin, E. Waterhouse, and the chairman.

**Lancaster.**—The Lancaster electricity works were inspected by the members of the Corporation on Friday afternoon in response to an invitation given by the Mayor in his capacity as chairman of the Electricity Committee. Mr. Tester, the electrical engineer, and his assistants conducted the party over the works. Representatives of the British Westinghouse Company, the chief contractors, were also present. The station contains four engines and dynamos, two of 300 kw. and two of 200 kw., each engine capable of running at 300 revolutions per minute. There is a condenser with a 25in. vacuum fed from cold-water tanks outside the station for each engine. A travelling crane capable of lifting 15 tons has been erected for use in case of repairs to the machinery, and as the flywheel of one machine weighs from four to five tons, it is conceivable that some such provision is an absolute necessity. In the evening the members of the Astronomical and Scientific Society, the science classes at the Storey Institute, and a large number of townspeople visited the works.

**Liverpool.**—The accounts of the Corporation electric supply department for the year ending Dec. 31, 1904, show, *inter alia*, the following particulars of expenditure: generation of electricity—coal, including cost of unloading, etc., £36,012; oil, waste, water, and engine-room stores, £5,198; wages at generating stations, £15,082; engines, boilers, dynamos, transformers, etc., £8,896—total, £65,192; distribution of electricity—wages, £1,746; repairs and maintenance of mains, £1,720; repairs and maintenance of meters, £516; repairs of machinery at distributing stations, £769—total, £4,752; rents, £1,990; rates and taxes on buildings, plant, etc., £14,441; management expenses, £11,455, including salaries of engineer's department and clerical staff, £8,275; special charges, £1,967; amount written off for bad debts, £113. The income was as follows: sales of electrical energy for lighting and power, £135,631; sales of electrical energy for public street-lighting, £2,571; sales of electrical energy for electric tramways, £91,674; rental of meters, £2,326; Allerton installation rentals, £29; rents of property, £650; manufacturing account, £3,718.

**Elland.**—The combined refuse destructor and electricity works of the District Council were opened in October, 1903, with 27 consumers, representing an equivalent of 2,191 8-c.p. lamps. By January, 1904, the consumers had increased to 59, representing 2,853 8-c.p. lamps, with 7 h.p. in motors, the units sold during the latter month amounting to 3,641. On Dec. 31, 1904, the consumers had risen to 97, and the units sold during the month to 9,255, there being connected the equivalent of 53·50 8-c.p. lamps and 72 h.p. in motors. The total units sold for the 12 months ended Dec. 31, 1904, was 46,054. In November, 1904, the destructor was shut down owing to there not being sufficient refuse; but in the months from January to November 2,621 loads of refuse were destroyed, together with 679½ loads of sludge from the sewage works. The works' costs show that the only fuel used, except, of course, the refuse and sludge named, up to the time of the destructor being shut down in November, was the small quantity required on the stand-by boiler while the destructor was cleaned out at regular intervals during the 11 months, and the cost of this fuel has only amounted to ·07d. ($\frac{7}{100}$d.) per unit sold. During December the current has been generated from fuel alone by means of the Babcock boiler, but the cost of such fuel has amounted to less than ½d. per unit sold, or ·43d. The oil, waste, and other stores for the 12 months have cost ·06d. per unit sold, while there has been no money expended on repairs. The wages of management and electrical staff have amounted to nearly 1½d., or 1·41d., per unit sold. The cost in men's wages destroying sludge and refuse has been 9½d. per ton. The revenue, at 2d. per unit for power purposes and 4d. per unit for lighting purposes, the price now in force, will amount to about £750, and the expenses of the department only amount to about £290 for the 12 months.

**South Africa.**—We are indebted to the *British South African Export Gazette* for the following particulars of electrical undertakings in South Africa. The Corporation of Pretoria have now completed the purchase of the electric lighting company's property, the shareholders having consented to accept the sum of £115,000 in 5 per cent. bonds, which works out at £1. 2s. for each £1 share. As already announced, considerable extensions are contemplated, for which the necessary funds are to be raised by loan. In the meantime a reduction in the cost of current is announced, lighting being now charged at 1s. per unit and power 5d. and 6d. according to circumstances. No rent is likewise charged for a single meter. The Potchefstroom Consumers' Electric Light and Power Company, Limited, have recently accepted the offer of the Town Council to purchase their undertaking for £6,000, which places the Council in a position to realise their scheme of an installation abreast with the requirements of this progressive town. The company's plant is small and its capacity limited, and it is intended to retain it only as a stand-by, and to erect an entirely new equipment on a scale answering to the town's actual needs An expenditure of £10,000 has been mentioned, but the plans have to be drafted, and when a complete survey is made, and a reckoning taken of future contingencies, it is probable that the outlay of a much larger sum will be decided upon. After having considered a number of offers from various bodies and firms, including that of Messrs. Harris, Lee, and Co., of Johannesburg, the Streets and Public Works Committee of the Mafeking Town Council have recommended that of Mr. J. Addison, of Kimberley, for acceptance, subject to a proper agreement being drawn up. The terms are roughly as follows: Mr. Addison to have the sole right to lay down plant for the supply of electricity and erect lines and appliances, and to supply and erect works and material for a period of seven years, at the end of which the Council to have the right to purchase the undertaking at a valuation plus 15 per cent. If not purchased, an extension is to be granted for a further period of 10 years, at the end of which the Council are to have the same right of purchase plus 5 per cent. It is provided that should the works not be commenced for six months, or the supply within 18 months, the concession is to be considered as lapsed. The Council is to furnish the site for the erection of the power station at a reasonable rent, and also defray the cost of the current for the public lamps, the concessionee bearing the charges of erection and maintenance of the lines, poles, and lamps. The Council will erect the fittings in the town hall, the concessionee supplying the current at the reduced rates for the public lighting. The system is to be a two-wire continuous 200-volt, and the generation by steam or oil, the lines being overhead and bare conductors used. The charges for current are: for lighting, 1s. 6d. per Board of Trade unit, with a meter rental of from 2s. to 7s. per month; for power, heating, cooking, ventilating mills, etc., 25 per cent. less. The minimum charge for current to each consumer is 5s. per month. Orders for the necessary material may be expected to be given out forthwith. The concessionaires of the Boksburg lighting scheme are Messrs. E. H. Gellender and Co., electrical engineers, Germiston, who have, we learn, already placed most of the orders for the plant. These include boilers by Messrs. Davey, Paxman, and Co., Limited, and Messrs. Marshall, Sons, and Co., Limited, and two compound engines by Messrs. Belliss and Morcom, Limited. The General Electric Company supply the two 100-kw. capacity dynamos. The system adopted is the three-wire, direct current, 800 volts pressure across the outers, the voltage to con-

Digitized by Google

sumers being 250. Street-lighting will be by 12 arc lamps and 30 incandescent lamps. The cost to the consumer is fixed at 1s. per unit. It is expected that the plant will be in operation by April next.

## PROVISIONAL PATENTS, 1905.

JAN. 30.

**1762. Means for electrically turning on and lighting up gas lamps, particularly those whose burners are beyond reach of hand.** William Pare, 11, Burlington-chambers, New-street, Birmingham.

**1792. Improvements in electric arc lamps.** Joseph Devonport Finney Andrews, 2, Park-avenue, East Sheen, London.

**1820. Improvements in or relating to electro-dynamic traction systems.** Julien Dulait, Constantin Zelenay, and Léon Rosenfeld, 111, Hatton-garden, London. (Complete specification.)

**1837. Improvements in the electrolytic production of metallic sheets, tubes, wire, strip, or the like.** Sherard Osborn Cowper-Coles, 4. South-street, Finsbury, London.

JAN. 31.

**1863. A new or improved method and arrangement for enclosing cables, electric wires, or the like.** Heinrich Rosner, 5, Corporation-street, Birmingham. (Complete specification.)

**1868. Improvements in electric lampholders and the like.** August Eckstein and Albert Julius David Krause, Peel Works, Adelphi, Salford.

**1874. Improvements in apparatus for regulating variable-ratio transformers.** Francis Lydall, Queen Anne's-chambers, Broadway, Westminster, London.

**1876. Improvements in apparatus for controlling the working of electrically-driven cars.** Francis Lydall, Queen Anne's-chambers, Broadway, Westminster, London.

**1878. Telephony.** Edward Alexander Buell, 65, Chancery-lane, London. (Complete specification.)

**1884. Electric system of fog signalling.** Alwyn Bruce Dawson-Moray and John Ffrench Fitzsimons, 3, Marshall-street, Golden-square, London.

**1891. Improvements in contact breakers of induction coils.** Mortimer Arthur Codd, 9, Elliscombe-road, Charlton, London.

**1912. Electric railway system.** Frank Eugene Kinsman, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**1919. Brush-holder for dynamo-electric machines.** James Burke, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**1920. Laminated cores for dynamo-electric machines.** James Burke, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**1921. Dynamo-electric machines.** James Burke, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**1943. An improved suspension device for electric lamps and the like.** August Günther, jun., 6, Lord-street, Liverpool. (Complete specification.)

**1951. A new or improved system of automatic block signalling for electric railways.** Fitzhugh Townsend, 18, Buckingham-street, Strand, London. (Complete specification.)

**29082A/04. Improvements in the means for the mutual electrical control of oppositely rotating members of turbines.** John Hubert Davies and Max Blieden, 1, Queen Victoria-street, London. (Date applied for under Patents Rule 9, Dec. 30, 1904.)

FEB. 1.

**1966. Improvements in or appertaining to mechanically or electrically propelled road vehicles.** Joseph William Allison, Palatine-chambers, Market-street, Halifax.

**1968. An electric carrying lamp.** Frank Greig Bucher, 37, West Nile-street, Glasgow.

**2004. Improvements in or relating to electric vapour lamps or enclosed arc lamps.** Charles Orme Bastian and George Calvert, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**2014. Improvements in or relating to electric distribution systems.** Alfred Julius Boult, 111, Hatton-garden, London. (Justus Bulkley Entz, United States.) (Complete specification.)

**2015. Improvements in or relating to brush-holders for electric dynamos or motors.** Laurence Checkley Barker and John Wesley Burleigh, 111, Hatton-garden, London.

**2022. Improvements relating to electric accumulators or secondary batteries.** Vickers, Sons, and Maxim, Limited, and Robert Frederick Hall, 7, Southampton-buildings, Chancery-lane, London.

**2030. Improved method and means for eliminating or reducing the influence of disturbing currents on telephone circuits.** Charles Mark Jacobs, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

**2033. A mechanically operated electric switch.** Stanley Matthews, 4, South-street, Finsbury, London.

**2039. Improvements in electric meters.** The British Thomson-Houston Company, Limited, and Frank Holden, 83, Cannon-street, London.

**2048. Improvements in windings for dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**22326A/04. Improvements in controllers for electric current.** Philip Middleton Justice, 55, Chancery-lane, London. (The Voltage Controller Company, United States.) (Date applied for under Patents Rule 9, Oct. 17, 1904.) (Complete specification.)

**22326B/04. Improvements in electricity transmission systems.** Philip Middleton Justice, 55, Chancery-lane, London. (The Voltage Controller Company, United States.) (Date applied for under Patents Rule 9, Oct. 17, 1904.) (Complete specification.)

FEB. 2.

**2066. Improvements in automatic controlling apparatus for operating electric switches or cut-outs.** Charles Mark Dorman, Reginald Arthur Smith, and Herbert George Bagga, Ordsal Electrical Works, Salford.

**2088. Improvements in brush-holders for dynamo-electric machines.** John Wesley Burleigh, Norfolk House, Norfolk-street, Strand, London.

**2108. Improvements relating to intercommunication telephone systems.** John Young, 322, High Holborn, London.

**2113. Improvements in combined overload and reverse current electric cut-outs.** The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

**2116. Improvements in alternating-current motors.** Valere Alfred Fynn, 18, Southampton-buildings, Chancery-lane London.

FEB. 3.

**2159. An automatic electric portable signal.** Henry Wallace, 10, Rosenau-road, Battersea, London.

**2172. Improvements in or relating to electric traction systems.** Wilfrid Swanwick Boult, 111, Hatton-garden, London.

**2189. Improvements in single-phase induction motors.** The Akt.-Ges. Brown, Boveri, und Co., 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, Feb. 4, 1904, being date of application in Switzerland.) (Complete specification.)

**2183. An improved form of contact breaker for induction coils and the like apparatus.** Alfred Henry Avery, Fulmen Works, Park-street, Tunbridge Wells.

**2199. Improvements in starting switches for electric motors.** Walter Angove Clatworthy, Alfred Holmes, John Henry Holmes, Leonard William Holmes, and Elwood Holmes, 47, Lincoln's-inn-fields, London.

**2194. Improvements in inspection boxes for electric light leads and the like.** James Wenham, 115, Cannon-street, London.

FEB. 4.

**2264. Improvements in and connected with means for generating electricity from heat.** William Anthony Turner, 14, Coleman-street, London.

**2266. Improvements in the construction of spring jacks for telephone switchboards.** Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Akt.-Ges.) (Complete specification.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published Feb. 23.*

1904.

**135. Alternating-current generators and motors.** Zani.

**2066. Electric receiving apparatus for telegraphic and other purposes.** Armstrong and Orling.

**2096. Apparatus for use in the distribution of alternating currents.** Berry.

**2277. Electric low-water alarm for boilers and the like.** Sugrue.

**2471. Electric alternating-current machines.** Latour. (Date applied for under International Convention, Feb. 2, 1903.)

**2580. Means for rectifying alternating current.** Weintraub. (Date applied for under International Convention, Feb. 2, 1903.)

**2734. Electric telegraphy.** Gáti.

**3000. Controllers for electric motors and other apparatus.** Laird and Todd.

**3244. Induction transformer for wireless telegraphy receiving stations.** Ducretet.

**3460. Circuit breakers and indicators for use with electric alternating currents.** Andrews.

**4176. Multiplex telegraphy.** Field.

**4512. Generating electricity by the use of moist chemicals which are mechanically pressed upon zinc.** Nehmer.

**6748. Electric switches.** Gore.

Digitized by Google

**7827. Electroliers, gas and oil pendants, and the like.** Sanders.

**8714. Electric switches.** Gore.

**12322. Speed control of high-pressure electric motors.** Boult. (De Kandó.)

**12707. Process for the production of electrical resistance bodies from amorphous or crystalline carbide of silicon or boron, or of silicon or other like suitable materials.** Thompson. (Chemische Elektrische Fabrik Prometheus G. m. b. H.)

**12729. Electric railways and motor vehicles therefor.** Sayer.

**13483. Combined electric regulating and measuring apparatus.** Fauvin, Amiot, and Cheneaux. (Date applied for under International Convention, Nov. 28, 1903.)

**15862. Conduits for underground electrical wires or cables.** Stone and Fenwick.

**19432. Electric automatic block signal and safety systems.** Finnigan.

**21138. Electromagnetic therapeutic apparatus.** Bachelet. (Date applied for under International Convention, Oct. 2, 1903.)

**21580. Contact devices for electric clocks.** Gustafson and Carlstedt. (Date applied for under International Convention, Oct. 8, 1903.)

**22171. Electric switchboards to protect persons from injury.** Elektrizitäts Act.-Ges. vorm. W. Lahmeyer und Co. (Date applied for under International Convention, Dec. 31, 1903.)

**23090. Methods of increasing the effective radiation of electromagnetic waves.** Stone. (Date applied for under International Convention, Oct. 30, 1903.)

**24470. Gas or vapour apparatus for electric lighting, rectifying, and other purposes.** Hewitt. (Date applied for under International Convention, Nov. 24, 1903.)

**26887. Apparatus for indicating the presence of faults and the like in three-phase electric circuits.** MacGahan. (Date applied for under International Convention, Jan. 20, 1904.)

**26915. Electrodes for arc lamps.** Dempster. (Date applied for under International Convention, Dec. 10, 1903.)

**26916. Arc lamp electrodes.** Steinmetz (Date applied for under International Convention, Dec. 10, 1903.)

**26918. Arc lamps and electrodes therefor.** Härdén. (Date applied for under International Convention, Dec. 10, 1903.)

**26919. Arc light electrodes.** Härdén. (Date applied for under International Convention, Dec. 10, 1903.)

**28349. Generation and distribution of electricity.** Dixon.

**28467. Electric incandescence lamps.** Thompson. (Deutsche Gasglühlicht Act.-Ges. Auergesellschaft.)

**28543. Electric junction and like boxes.** Manquais.

**28554. Thermoelectric couples.** Boult. (Hoskins.)

**28608. "Electric candle" lamps.** Regnart and Hunter Electric Candle Lamp Company, Limited.

**28629. Drop signals or annunciators for central telephone stations and so forth.** Birnbaum.

**28722. Electric incandescent lighting devices.** Schwabe.

**28723. Electric incandescent lighting devices for shop windows, show-cases, and the like.** Schwabe.

**28724. Electric incandescent lighting devices for billiard tables, exhibition tables, sale counters, and the like.** Schwabe.

**28962. Galvanometers.** Richard. (Date applied for under International Convention, Feb. 3, 1904.)

**29054. Electric incandescent lighting devices for pictures, music desks, writing desks, pianofortes, and the like.** Schwabe.

**29059. Electric ignition plugs for internal-combustion engines.** Renault. (Date applied for under International Convention, May 2, 1904.)

**29233. Low-tension electric ignition devices for internal-combustion motors.** Albion Motorcar Company, Limited, and Murray.

**29310. Electrical dumb-bells and similar appliances for physical exercises.** Loebl.

**29347. Electric transformer.** Stern.

**29423. Automatic photographing telegraphs.** Ribbe.

## NOTES.

**Electro-Harmonic Society.**—The 24th inst. will be a "ladies' night," and proceedings will, as usual, commence at 8 o'clock. An excellent programme has again been arranged, the vocalists being Mr. Arthur Strugnell and the Misses Mabel Mawson and Carmen Hill, while instrumental music will be provided by Mr. T. E. Gatehouse and the orchestra. To complete the evening's entertainment, variety performances will be given by Messrs. E. Douglas, F. Leedham, and W. Graham.

**Wireless Telegraphy.**—The Pacific Islands Phosphates Company are so impressed with the success of the installation of wireless telegraphy in the Sandwich Islands that they are investigating the problem of connecting their group by the same means. The group of islands over which the company's operations extend is a large one, but no individual island is further than 200 miles from its nearest neighbour. The group is about 1,000 miles distant from the Fijian cable station, and, according to latest advices, there is a talk of endeavouring to also connect the islands with China by means of wireless telegraphy, and thus bring the group into direct communication with the whole world. It is, however, apparent that for such a great distance a very powerful and large installation would be required at both ends.

**Historical Exhibition.**—An historical exhibition of rare and curious objects relating to medicine, chemistry, pharmacy, and the allied sciences is to be held in London shortly, organised by and under the direction of Henry S. Wellcome. The exhibition will be strictly professional and scientific in character, and will not be open to the general public. We notice that part of a special section (Section VII. B) has been set apart for curious magnetic and electrical appliances. Section II. deals with rare and curious manuscripts, incunabula, books, periodicals, pamphlets, and book-plates on and connected with medical, chemical, pharmaceutical, and allied scientific subjects. We understand that Mr. Wellcome will be pleased to receive at Snow-hill-buildings, London, E.C., any curiosities or apparatus of the medical and allied sciences.

**Motor Omnibuses.**—The competition of electric trams has been a sore point with the railway companies, and now the latter are entering on a form of enterprise which the municipal tramway authorities deem it necessary to take certain precautions against. At a conference of 22 of these authorities, held in London on Monday, Councillor Boyle (chairman of the Manchester Corporation Tramways Committee) presiding, it was resolved to oppose the proposals of several railway companies made in private Bills this session to run motor omnibuses, unless the routes were restricted to the railway stations of the company and fixed points in the vicinity. It was also agreed to support the Bill of the Automobile Club and the Cyclists' Touring Club, providing that all vehicles using the highways after dark shall be compelled to carry a white light in front and a red light in the rear.

**Municipal Wiring.**—A special meeting of the Electrical Contractors' Association was held held last Friday at Frascati's Restaurant to protest against Clauses 63 and 64 of the London County Council General Powers Bill, which propose to confer power upon the borough councils of the Metropolis to execute the wiring of consumers' premises. The hon. solicitor, Mr. R. Tweedy Smith, contended that such powers would lead to municipal trading in its worst form. Large sums had been invested by private firms in the electrical contractors' industry, and there was already great competition. If powers were given to the borough councils to carry on the business of electrical contractors, they would practically have a monopoly in the areas of their supply. It was unfair, he concluded, that the ratepayers' money should be utilised for carrying on such private enterprises as wiring and fitting the premises of consumers in competition with the ratepayers themselves. A resolution was carried that the members should use every endeavour to prevent the passage of the clauses in question, and it was decided to approach the President of the Board of Trade on the matter.

**Non-Sparking Poles.**—In the earlier days of dynamo design, when sparking rather than heating was a limit against which the designer had to contend, the introduction of auxiliary poles was frequently discussed, and often tried with and without success. Such poles have been adopted by one large firm in this country in connection with their turbine-driven direct-current generators, where the commutating troubles are exaggerated by the high speed and consequent few turns in the armature. For this purpose auxiliary poles have been quite successful, and they have enabled large turbo-generators to be worked successfully with fixed brushes at any load. We notice in the *Street Railway Journal* a description of this class of non-sparking pole for another object—*i.e.*, to enable a shunt-wound motor to have its speed varied over a wide range. In the machine in question, which is a four-pole one, the main field coils are shunt-wound, and there are four auxiliary series-wound poles in between them. The device is said to be exceedingly serviceable, as the auxiliary poles always give a correct field for commutation. It is claimed that in this motor, with the brushes placed equidistant between the poles, the direction of rotation may be reversed without any sparking taking place. It runs sparklessly with a variable load as well as at variable speed. The motors of this type are being put on the market in the States by the Electro-Dynamic Company of Bayonne, New Jersey.

**The Domestic Uses of Electricity.**—In the issue for Feb. 15 of *The House Beautiful*, Sir David Salomons writes upon "Electricity in the Home." This article deals with the Protean applications of electricity for domestic purposes. After describing its uses for ordinary and ornamental illumination, Sir David enumerates its special functions in the different rooms. For ventilation it is a convenient agency throughout the house. Then there is the electric radiator, which, if somewhat expensive at present for general use, is a great convenience in the bedroom or the bathroom, or for making a cup of coffee. Nor has Sir David omitted its use to the amateur photographer or in the sick-room, where the value of electro-therapeutics is gaining wider recognition. In addition to these, there is the telephone and the electric bell, to say nothing of the apparatus for frustrating the cult of Bill Sikes. Another article, entitled "The Wonders of Broomhill," describes how Sir David has given practical effect to his views at his seat in Kent. Not only is electricity employed in manifold ways for domestic purposes, but there is a power station where energy can be generated up to 100 h.p., a storage battery, and some workshops containing a variety of machinery. The beautiful picture gallery is artistically illuminated by electricity, which also finds its way into the billiard-room for automatically marking the scores. The articles contain a lot of interesting matter, and are admirably illustrated.

**The Lyons-Moutiers 57,000-Volt Transmission.**—An interesting transmission of energy is about to be undertaken between Moutiers, in Tarentaise, and Lyons, a distance of about 113 miles. The actual power to be transmitted is about 4,700 h.p., which, with the distance,

Digitized by Google

makes a record, we believe, for Continental practice. The work is to be carried out for the Société Grenobloise de Force et de Lumière by the Compagnie de l'Industrie Electrique et Mécanique de Genève. For the purpose the contractors are about to instal four pairs of dynamos at the generating station at Moutiers, and there will be at the receiving end of the line five groups of double motors with all accessories. It is an interesting fact that under the order for this equipment the plant will work on the continuous-current series system. This system has, however, been largely used in the district in question, and has worked successfully between Saint-Maurice and Lausanne, a distance of 36 miles. In this case, however, the maximum voltage did not exceed 22,000, so that there will be a considerable jump in the present instance, as at full load the voltage at the generating station is calculated to be 56,960. With this voltage the horse-power above mentioned will be transmitted over the distance of 113 miles by means of two copper wires 9mm. in diameter. At the point where the line enters the town of Lyons underground cables are to be used, which will be highly insulated and armoured. Allowing for the loss on the line these cables will still have to stand a voltage of 50,000. While the continuous-current series system greatly simplifies the line construction, it seems to us that the insulation of the generators and of the receiving motors will need very careful attention.

**Electrical Exhibition Scheme.**—Under the auspices of the National Electrical Manufacturers' Association, a meeting of the industry was held at the Hotel Cecil on Wednesday, when a proposal to hold a general electrical exhibition was approved. The attendance was somewhat limited, but Mr. Walter Davenport, the secretary, who was voted to the chair, read numerous letters from metropolitan and provincial firms promising their support. It is proposed to hold the exhibition in October at Olympia or the Crystal Palace, probably the former. A month was spoken of as the duration of the exhibition, but this remains to be finally settled. The arrangements will be carried out by an executive committee of 15, composed of 10 nominees from the exhibitors and four from central-station owners, while a representative of the electrical Press is also to be invited to officiate. Of the 10 members to be selected by the exhibitors, half will be composed of members of the association and the remaining five will be elected from the other exhibitors. The voting for the five members of the executive to be selected from the members of the association resulted in the following houses being nominated to appoint representatives: General Electric Company, Edison and Swan, Verity, Limited, Electric Power Storage Company, and the International Electric Company. Under terms provisionally agreed upon exhibitors will incur no liability beyond the rent for space, so that should the exhibition fail to succeed the loss will be comparatively small; but Mr. Davenport intimated that, with the numerous assurances of support that had been received, there was every prospect of success, and the lines upon which the exhibition was to be run would ensure the exhibitors, and not professional promoters, benefiting by the profits.

**Smoke Prevention.**—In the course of his address the other day to the Society of Experimental Engineers at Dundee upon the economical use of coal, Mr. H. Richardson, the city electrical engineer, dealt largely with the smoke nuisance, and urged the necessity of further investigation into this matter. The first part of the lecture was somewhat reminiscent of the paper lately presented to the Institution of Electrical Engineers by Messrs. Booth and Kershaw. Improperly designed furnaces, Mr. Richardson held, were responsible for a great amount of the smoke nuisance, and they should get away from the present rule-of-thumb method of building these. Smoking chimneys were quite unnecessary, for the smoke was a sign of imperfect combustion, and therefore showed an uneconomical use of fuel. He went on to show that if those old-fashioned methods of designing furnaces were departed from, and the real principles of combustion recognised, more economical results would accrue, besides attaining nearer to the absolutely smokeless chimney shaft. The whole trouble, he said, was due to designers following the old way, although they had kept up-to-date in the design of pressure-resisting machines, boilers, etc. Referring to the waste gases, Mr. Richardson suggested that these should be analysed on their way to the chimney, and records kept, so that engineers and managers of works might know exactly the state of their combustion. One of the chief causes of the smoke trouble, especially in the North Country, was the fact that bituminous coal was used, unconsumed hydrocarbons, due to imperfect combustion, being also responsible for it. Where anthracite coal was used, very much less trouble with smoke was experienced. In conclusion, he stated that investigation into the combustion question would repay trouble more than any other department of steam-plant engineering.

**London Electric Supply Corporation, Limited.**—We have to congratulate this company on the fact that it has at last reached the stage when it is able to pay a dividend upon its ordinary stock. This company was registered in 1887, although it had been in existence under another name since 1885. It was responsible for pioneering work in the transmission and distribution of electrical energy which has been invaluable to other undertakers. In the earlier days Mr. S. Z. de Ferranti was responsible for the undertaking, and under his advice works were laid down at Deptford from which power was transmitted to London. Mr. Ferranti's ideas as to the generation of electricity outside London, where coal can be cheaply obtained and there is ample water for condensation purposes, have proved to be absolutely correct. Unfortunately, at the time when the Deptford works were started, the experience to enable this to be successfully done had to be dearly bought. Cables to stand the high voltage necessary for such transmission had to be specially designed, and the paper-insulated cable, so largely used throughout the world to-day, may be said to have developed from the Ferranti tubular mains manufactured at Deptford. The result of this pioneering work was to hamper the company with a vast amount of unremunerative capital, but those responsible for the management, of whom Mr. R. Stewart Bain must be given the first place, have carried the matter through in spite of discouragement. Lord Crawford and Mr. Partridge, the chief engineer of the company, have also been with the company throughout, and are to be congratulated on the fact that they have so far overcome their financial difficulties as to be able to declare a 3 per cent. dividend on the ordinary shares. The accounts of the company are reproduced elsewhere, and show that during the past year the number of units sold increased from a little over four millions to 10½ millions.

**Tramways and Light Railways Association.**—Continuing its policy of inspecting the power stations of the electric railways and tramways, a considerable party of this association paid a visit last week to the generating station of the London United Tramways Company. At Chiswick the party were received by the managing director, Mr. J. Clifton Robinson, who escorted them round and pointed out the main features of interest. They first saw the car sheds, where 75 out of the 300 cars in regular use are

Digitized by Google

housed, and were then taken through the repairing shops. A tour was next made of the boiler-room, with its range of 11 Babcock and Wilcox boilers, each capable of evaporating 11,000lb. of water an hour. Descending below the boilers, the party inspected the steam-pipe connections with the engines, all placed out of sight, yet readily accessible. Finally they emerged into the engine-room, with its five Allis vertical cross-compound engines, three of 500 kw. capacity and two of 1,000 kw., supplying power to the whole of the company's extensive system. The annual meeting was held on Friday at the Society of Arts, Mr. Alfred Baker, the president, in the chair. The following gentlemen were elected to fill vacancies on the council: Mr. Arthur Stanley, M.P., as president; Mr. H. England, Mr. J. B. Hamilton, Mr. J. H. Rider, Mr. S. Sellon, and Lord Vaux of Harrowden. After the chairman had introduced the newly-elected president, Mr. A. Stanley, M.P., the latter took the chair. In the course of his address he expressed the belief that if anybody invented a cheaper mode of traction than that of a metal wheel on a metal rail it would run trams off the road, but it would not be done by motor omnibuses. In conclusion, he stated that a meeting had been arranged with the Association of Municipal Corporations, and the council hoped that one result of it would be a joint representation to the Government, with the view of doing away with some of the obsolete forms and anomalies at present existing.

**Electro-Acoustic Sea-Sounding Device.** — An electro-acoustic method of sea-sounding where it is unnecessary to touch bottom has recently been devised by Mr. H. Berggrof, a Norwegian engineer, and a description of the apparatus is given in the *Scientific American*. The depths are also registered graphically upon a revolving drum. The operation of the device depends upon the time which sound takes to travel to the bottom and return, and the measurement of the time thus gives the depth to which the exploring apparatus is lowered. According to experiments, it is found that sound takes one second to make the double distance of 2,000ft. In the inventor's recent trials, the vessel was equipped with an acoustic tube which could be lowered into the water. By means of an ordinary clock he could take the depth with considerable precision; thus, four seconds shows about 8,000ft. For more exact work he used a registering apparatus, in which the depth is indicated on a band of paper. The apparatus consists of three parts—a transmitter, an acoustic receiver, and a chronometer. The sound is formed at intervals by a revolving disc which turns slowly and carries a projection on the periphery. The latter is made to strike against a fixed point, and thus makes an electric contact at each revolution. The electric circuit has a magnet which operates a vibrating armature, and each time the contact is made a sound is sent toward the bottom of the sea, whence it comes back to the vessel and is received in a microphone. The microphone is specially constructed so that it is only sensitive to sounds for which it is tuned, by means of a resonator. The vibrator is tuned to the same pitch, so that the membrane, upon receiving the sound from the bottom, will vibrate, and this movement is registered in the apparatus, taking account of the time which has elapsed between the closing of the electric contact and the reception of the sound in the microphone. The apparatus is said to have worked very successfully.

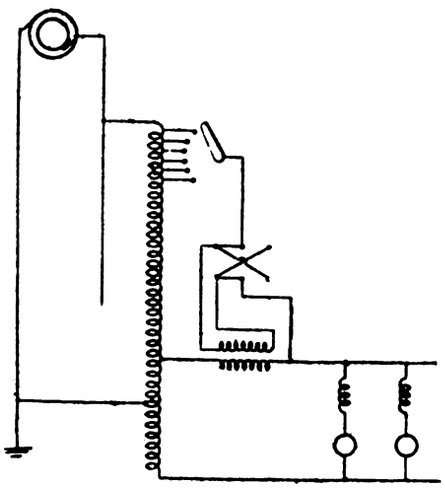
**Birmingham Electric Club.**—At a meeting of this club held on Saturday last, a paper was given by Mr. E. R. Wood on "The Starting and Speed Regulation of Electric Motors." Mr. Wood remarked at the outset that to secure a satisfactory performance from a motor a reliable starter was a *sine qua non*. He pointed out that numbers of starters in use could be improved by a better gradation between the stops—*i.e.*, that although the total resistance might be correct in ohmic value, owing to the unsuitable divisions in that resistance, violent sparking occurred while the contact lever passed over the last few stops. The lecturer suggested grading the resistance so that the amounts between the several stops were in a geometrical progression in the case of shunt-wound motors, but this law must be departed from for series-wound motors in order to reduce the sparking voltage to a minimum. This method would be found to give the best all-round results. The difference between the general starting conditions of shunt and series wound motors was then reviewed, and illustrations given of the advantages to be derived by employing the series-parallel control for tramway purposes. Interesting descriptions were given of different methods for obtaining speed variation by alteration of the supply voltage and by shunt regulation. Because starting switches, as a rule, only have current passing through their contacts for but a very short time, these contacts may be made for a comparatively high current density. This, however, is sometimes carried too far, notably in the case of the surface-contact density between the brushes and contact segments in many controllers. Various methods that have been introduced for prevention of overheating of resistance conductors and for the prevention of oxidation were dealt with. The advantages of compounding motors, cumulative series winding to increase the torque, and cases where the series coils are afterwards cut out in order to secure a practically constant speed, were also dealt with. The paper was well discussed.

**Obituary.**—Those members of the Institution of Electrical Engineers who toured the United States last autumn will hear with deep regret of the decease of Mr. Edward H. Mullin, who acted as chairman of the Transportation Committee on the occasion of the International Electrical Congress at St. Louis, and took a prominent part in carrying out the arrangements connected with the visit. From a memoir of Mr. Mullin appearing in the *Electrical World* of New York, we notice that he was born at Castlederg, co. Tyrone, in 1859, so that he has passed away at the comparatively early age of forty-five. He graduated with honours at Queen's College, Belfast, where he took a special interest in physics, and a little later he proceeded to the States. For some time he was associated with the New York *Times* and other prominent dailies, but his sympathies strongly tended towards scientific and technical subjects, and he devoted himself to this branch of journalism with enthusiasm, contributing extensively to periodicals on both sides of the Atlantic. In 1898 his work in this field attracted the attention of President Coffin, of the General Electric Company, who appointed Mr. Mullin head of the company's publication department. Enjoying the confidence of the Press, Mr. Mullin's services were of great value to the company in removing misapprehensions and setting both sides of the case before the public. Under Mr. Mullin's supervision the company's bureau of intelligence reached a high standard of efficiency. Of his interest in technical journalism our contemporary remarks that "it is not saying too much to include him among the potent influences which, during the last 10 or 15 years, have so perceptibly raised the general standard in this field." Mr. Mullin was for many years actively associated with the American Institute of Electrical Engineers, and at the time of his death was a member of the council. He was also connected with several other electrical organisations, and possessed an extensive knowledge of technical matters. He will be missed the more because, to qualifications of an

Digitized by Google

uncommon order, he united a genial personality and a high standard of integrity, which gained him the esteem of all he came in contact with.

**Single-Phase Alternating-Current Distribution.** A patent for a single-phase alternating-current system of distribution has recently been granted in the United States to Mr. P. M. Lincoln, who has assigned it to the Westinghouse Company. From a brief description given in the *Electrical Review* of New York, it appears that the object of the invention is to provide a system in which energy may be transmitted at high voltages and delivered through voltage-regulating apparatus to translating devices at lower voltages, and in which the differences of potential between the grounded conductor from the source of energy and the respective terminals of the translating devices are reduced to safe and limited values. It has been suggested that motors of the commutator type of construction having series-connected armature and field-magnet windings, and being similar in many respects to ordinary direct-current motors, should be operated by alternating current. Various systems have been devised for transmitting energy at high voltages and supplying it at variable low voltages to motors at the points of consumption. The feature of the present invention is that, unlike a previous system, the differences of potential between the respective motor terminals and



the grounded conductor are only one-half that between the motor terminals. With this arrangement the stresses on the insulation and the dangers incident to the operation or repair of the motors are materially reduced.

**New Publications.**—"'N' Rays," by R. Blondlot, translated by J. Garcin. (London: Longmans, Green, and Co. 3s. 6d.) This volume comprises Prof. Blondlot's communications to the Académie des Sciences upon the subject of "N" rays, and is supplemented by instructions for making phosphorescent screens suitable for the observation of the rays.—We have received the January number of the *Proceedings* of the American Institute of Electrical Engineers, which contains papers on "Acyclic (Homopolar) Dynamos," by J. E. Noeggerath; and "Modern Central-Station Design," by J. E. Moultrop; also the discussion on "Problems of Heavy Electric Traction."—A reprint of a paper entitled "The Absorption of Electromagnetic Waves by Living Vegetable Organisms" has been forwarded to us. The author, Major G. O. Squier, of the United States Army Signal Corps, details some experiments in wireless telegraphy carried out by him at the manœuvres held in California last August. It had been noticed in some previous manœuvres that in laying rapid telephone lines in a wooded country for the field exercises of the army, a much better ground could be obtained by attaching the earth side of the instrument to an iron nail driven into the trunk of a tree or shrub than by the ordinary method of burying a conducting plate. Major Squier found that in California, where it was almost impossible to use the ordinary single-wire grounded circuit on account of the extremely dry condition of the soil, a ground connection could be established in a few moments by using a tree. He conducted some simple experiments in wireless telegraphy with vegetable antennæ, and the results prompted him to suggest that the matter was worthy of further investigation in order to see what could be accomplished by the use of more elaborate apparatus than were available when he conducted his tests. There is some talk of such an installation between one of our groups of islands in the Southern Pacific. The idea suggests an interesting field of research, and Major Squier, in concluding his remarks, puts in a plea for the more systematic study of vegetation from a distinctly physical standpoint.—"The Inventors' Guide," by Jas. Roberts (London: John Murray. 2s. 6d). The author has compiled a comprehensive treatise on the patent laws, including the regulations which recently came into force.

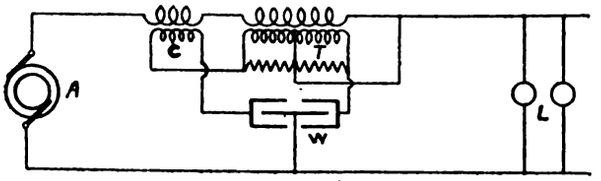
**British Association.**—Activity is being evinced at the various centres of the South African Association for the Advancement of Science, in view of the visit of the British Association in August. It is proposed that sub-committees of the local committees shall be formed to deal with the different matters arising out of the tour, and in order to co-ordinate the proceedings a central executive committee, under the chairmanship of Sir David Gill, H.M. Astronomer at the Cape of Good Hope, with whom the secretaries of the local committees will consult in organising the programme, has been constituted. According to the provisional arrangements, the visitors will land at Cape Town on Aug. 15, when the presidential address will be delivered, the remainder of the week being devoted to meetings in the mornings, and lectures, social functions, and excursions in the afternoons and evenings. The Saturday will be entirely devoted to excursions, and in the evening of the same day a special steamer will leave direct for Durban. About two days will be devoted to Durban and Pietermaritzburg, and another couple of days to the Natal battlefields, Johannesburg being reached on Aug. 28. The rest of the week will be spent on the Rand and in Pretoria, the party proceeding thence to Kimberley, *vid* Bloemfontein. A couple of days will be spent at each of the latter places, and then a move will be made for Bulawayo, and finally for the Victoria Falls. If a minimum of 100 members decides in sufficient time to return to England *vid* Beira from Rhodesia, the Union Castle Steamship Company will provide a special steamer sailing by the East Coast and Suez Canal. It is probable that at Cape Town and Johannesburg hospitality will be provided for at least 200 guests, special accommodation being prepared for the secretaries of the sections so as to facilitate their work. Meetings of all the sections will be held both in Cape Town and Johannesburg, and the South African Association are seeing to it that nothing shall be lacking at those places in the way of accommodation for the meetings and facilities for the transaction of business in the most convenient manner. The local committees are also making arrangements for extending private hospitality or providing free hotel accommodation for the visitors, it being understood between the British and South African Associations that only distinguished scientists shall be invited guests.

**The Metropolitan Railway.**—A correspondent to the *Times*, while acknowledging the good points of the new electric service between Baker-street and Uxbridge, has one or two grievances to ventilate. The corridor type of carriage has generally been regarded as an advance in the construction of rolling-stock, but this gentleman evidently does not participate in that view. It is all very well for

Digitized by Google

tubes, he says, but when the passenger gets beyond Finchley-road, where the underground section of the Metropolitan Railway ends, he is exposed to a cutting blast, if there is any wind about, every time the doors are opened. The *Times* correspondent considers this not only highly disagreeable, but positively dangerous, and he even indulges in the dismal prediction that to travel on this line will mean a sure journey to the tomb. The older form of carriage is not without its comfortable features, but it really seems as though this gentleman is conjuring up an imaginary bogey when he paints the peril of the corridor train in such a .sombre hue. The American death-rate does not appear to have been accelerated from this cause. The same gentleman urges the following further objection: "Under the old dispensation the man of business had come to look upon his journey to and from the City, if not with pleasure, yet with a chastened affection. It supplied him with two fairly quiet intervals in the day. . . . These oases of comparative peace are now denied him. At intervals of two and three minutes, and with a clang of metal that suggests the bursting of the gates of Hades, the doors fly open and stentorian tones, before and behind, tell him where he is. A half-minute draught and unrest and the doors clang to, and the tones announce with similar and unpleasant emphasis where he will be presently." If the stations could be announced by some improved form of automatic indicator, such a device would probably meet with appreciation, and perhaps railway companies will give this matter fresh consideration. The *Times* correspondent has still another grievance in the abolition of the second-class, stating that it is especially hard on those who cannot afford to travel first-class, but are willing to pay a little extra "to avoid the honest, though rough and emphatic, personalities that pervade many of the trains." These passengers, however, represent a comparatively small section, and scarcely justify the confusion and waste of time consequent upon additional classes, especially as the difference between the first and third class fares on this section of the Metropolitan Railway does not in general, if at all, exceed 50 per cent.

**Electrostatic Wattmeter.**—A patent in connection with an electrostatic wattmeter has recently been granted in the United States to Mr. Miles Walker which substitutes for the resistance, as a source of E M.F. proportional to the load current and in phase therewith, a step-up series transformer. The electrostatic wattmeter has not found an extensive use in commercial work, because the forces which act upon the moving member of the instrument when connected up in accordance with the ordinary method are so small as to necessitate the employment of an instrument which is extremely sensitive and delicate. Under the ordinary practice, the voltage which is applied to the quadrants of the instruments is secured by passing the main current through a non-inductive resistance which necessitates the utilisation of a low voltage in the instrument in order to avoid the large loss of power which would otherwise result in the non-inductive resistance. Mr. Walker's invention, of which a description appears in the *Electrical World*, is designed to eliminate the objections to the use of large voltages. The connections are illustrated in the accompanying diagram. A difficulty in using a plain series transformer in its simplest form is found in the fact that the E M F. measured across the open-circuited secondary coil will be perhaps 40deg. out of phase with the primary current, due to the predominating influence of the magnetising component of the primary current. The inventor, therefore, places a non-inductive resistance across the secondary of the transformer, the effect being that the current which flows through the resistance in phase with the secondary E.M.F. necessitates an opposing component in the primary, and the resultant primary current is caused to be more nearly in phase (opposition) with the secondary E.M.F. In order to shift the phase of the E.M.F. applied to the quadrants so as to bring it directly in opposition to that of the main line current, the inventor uses the compensating transformer shown at C in the illustration.



This transformer has a core provided with a partially short-circuited air-gap so that its secondary E.M.F., which is added vectorily to the secondary E.M.F. of the main series transformer, T, may be in the proper phase position with respect to the primary current to compensate for the lack of exact phase opposition referred to as above.

**Obituary.**—We regret to hear of the death of Mr. C. J. Sutherland, who for many years held the position of city electrical engineer at Worcester. It was only a short time ago that we announced his retirement from that post, and expressed a hope that complete rest would enable him to recover his health. Unfortunately this was not to be.

Mr. Sutherland died on the 30th ult. His experience in electric light distribution went back to the early days of the Eastbourne Company, and he also saw the pioneering work in connection with the first Brompton and Kensington station. After experience at the Stanhope-street station of the St Pancras Vestry, he was appointed assistant engineer to the Hanley Corporation electricity works in October, 1894. In the following June he was appointed joint manager and electrical engineer of those works in conjunction with Mr. C. A Cowell. After holding this post for over three years, he was appointed in November, 1898, city electrical engineer at Worcester. The supply in that city was then being given on the single-phase alternating-current system from works 2½ miles away. With the extension of the supply it was found necessary to put down new works in the city, and these were designed by Mr. Sutherland, and carried out under his supervision. This new station at Hylton-road was completed in 1902, and will serve as a fitting monument to the late engineer for years to come. Mr. Sutherland was highly respected by his committee and staff, and by his colleagues in the electrical profession. He leaves a widow and one little son to mourn his loss.

## THE LOTS ROAD POWER STATION.

*(Concluded from page 194.)*

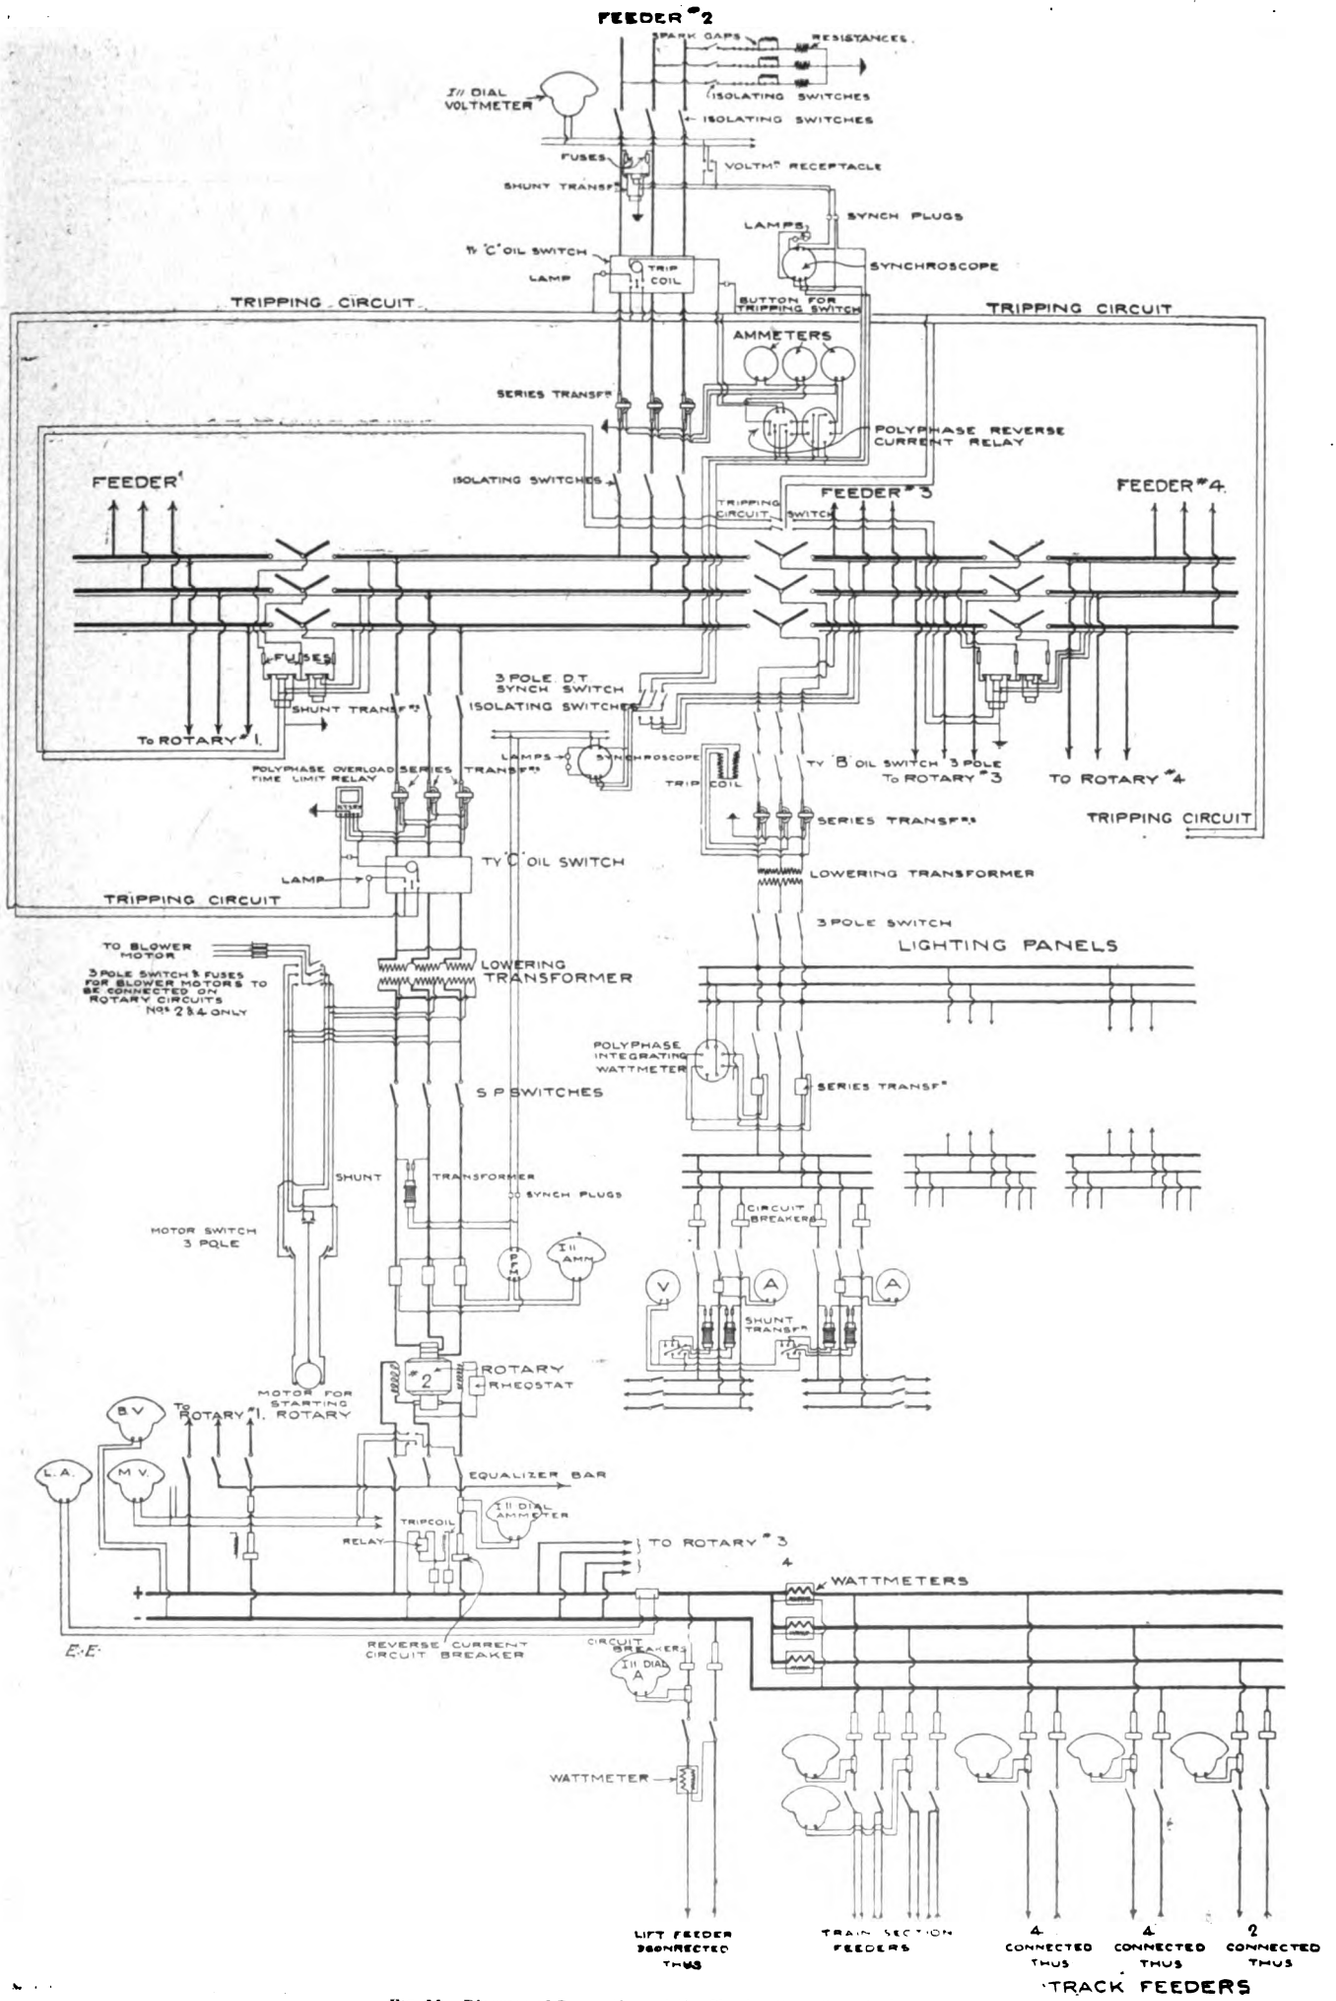

FIG. 14.—Diagram of Connections at the Charing Cross Sub-Station.

Digitized by Google

In our last issue we completed the description of the switchboard and auxiliary plant in the above power station. This week we propose to treat of the sub station plant for which the British Westinghouse Company have been the contractors. The sub-stations of the Metropolitan District Railway supply direct current to the southern half of the Inner Circle, and to a very wide area, extending from East Ham to Hounslow and from Sudbury to Wimbledon and Richmond. These points form approximately the bounds of the company, and are all primarily supplied with power from Lots-road. As all the sub-stations are to a great

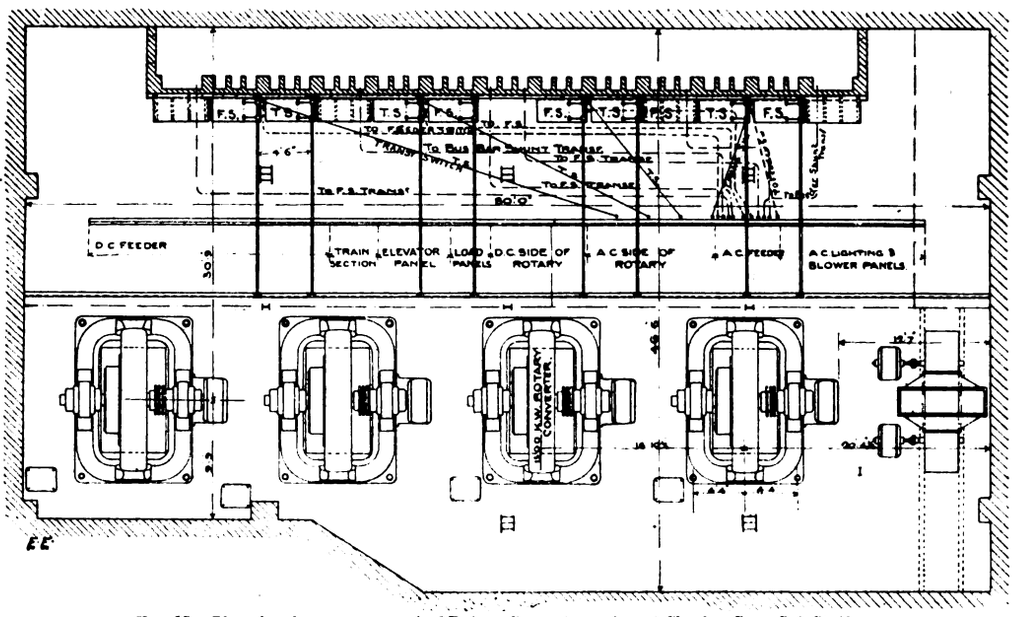

FIG. 15.—Plan showing arrangement of Rotary Converters, etc., at Charing Cross Sub-Station.

degree similar in design and construction, it will suffice to select one of them—viz., that at Charing Cross—for description. Three-phase current at 11,000 volts is supplied to this sub-station from Chelsea by means of four feeders, and, after being converted to direct current at approximately 600 volts, is conveyed by 24 cables to the track rail. In addition, there are direct-current feeders that supply current to the tube stations for operating the lifts, and alternate-current feeders set apart for the lighting of the stations and tunnels.

Fig. 14, which is a diagram of connections at Charing Cross sub-station, shows the system upon which it is

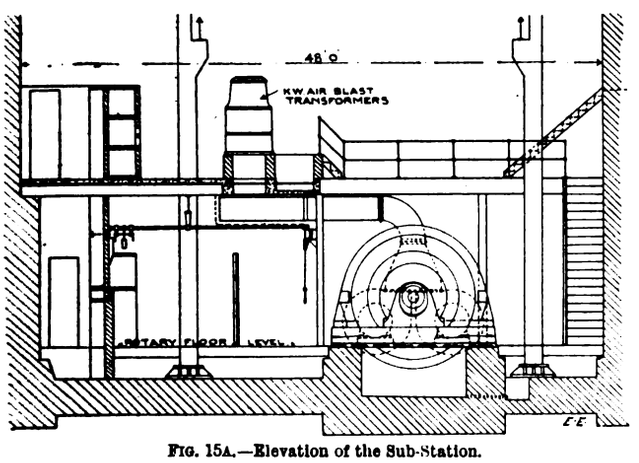

FIG. 15A.—Elevation of the Sub-Station.

operated, and Figs. 15 and 15A give a plan and elevation, from which an idea of the general lay-out of the plant can be obtained. The following details of the equipment are of special interest. Westinghouse spark-gap lightning arresters protect the feeders directly upon their entrance into the building, after which they pass to isolating switches of a single knife pattern, and operated by a long insulating pole fitted with a hook at the end. These switches are, of course, only used upon rare occasions, their function being to cut the pressure off from the oil-break feeder switches when cleaning or repairs are to be undertaken. Like arrangements are made upon the other side of the oil switches—that is, between them and the 'bus bars. Reverse current relays are installed for the protection of the high-tension feeders from the sub-station end, and thus if a short-circuit occurs on any feeder, current will not flow to it from the sub-station 'bus bars. As will be seen from Fig. 14, the main high-tension 'bus bars are divided into four sections, each of which has one feeder and one rotary converter connected to it. By the means of selector switches of the same type and method of operation as the isolating switches, these 'bus-bar sections may be so connected as to use the feeders separately or in parallel as desired, and similar selector switches being included in the rotary circuits, a very flexible and convenient arrangement is secured. The pressure transformers used in connection with the measuring instruments are also provided with selector switches, and thus may be fed from any particular pair of 'bus bars if necessary. The transformers for the alternating-current lighting circuits are connected to the middle set of 'bus-bar selector switches, which arrangement makes it possible to supply the load from either pair of incoming feeders.

The circuit to the primaries of the step-down transformers is completed by isolating and main oil switches in series, and connection is made from the secondaries to the collecting rings of the rotaries through sets of three single-pole knife switches. The main oil switch of each converter is in the ordinary way hand operated, but it is also fitted with an overload time-limit relay, which comes into operation, automatically tripping the switch, if a prolonged short-circuit or overload occurs. In addition, there is a push on the switchboard, the pressing of which will electrically open the main switch. Two knife switches, one for each pole, are provided for the direct-current side of the rotary converter, and there is also a reverse-current circuit breaker in the negative side and the usual equalising switch, which latter, however, is not placed on the switchboard, but on a cast-iron pillar close to the machine. A small induction motor, coupled direct to the shaft, is provided for starting each rotary, and its switch is placed on the alternate-current converter panel of the switchboard.

As direct current is supplied from this sub-station to three railway systems controlled by the Underground Electric Railways, Limited, it has been necessary to split the positive 'bus bar up into three sections on the far side of the main load panel, and in each of these is interposed a suitable direct-current integrating wattmeter. The first and second meter the power in one train section and four track feeders, the third, that in two track feeders. The three other cables that convey the current for operating the lifts are fitted in a like manner.

All lighting is carried out on the three-phase system, each sub-station being responsible for as much as lies halfway between it and the neighbouring ones. By the use of interconnecting switches it is possible, however, to couple up the

Digitized by Google

sections, so that the lighting will not be interfered with in the event of a sub-station breaking down or being stopped. A Westinghouse type B triple-pole automatic oil switch is interposed between the main switchboard and the high-

The instruments and controlling gear of the switchboard are mounted upon polished blue Vermont marble panels, which collectively give a total length of 69ft. 4in. Referring to Fig. 16, and beginning from the right-hand side, there

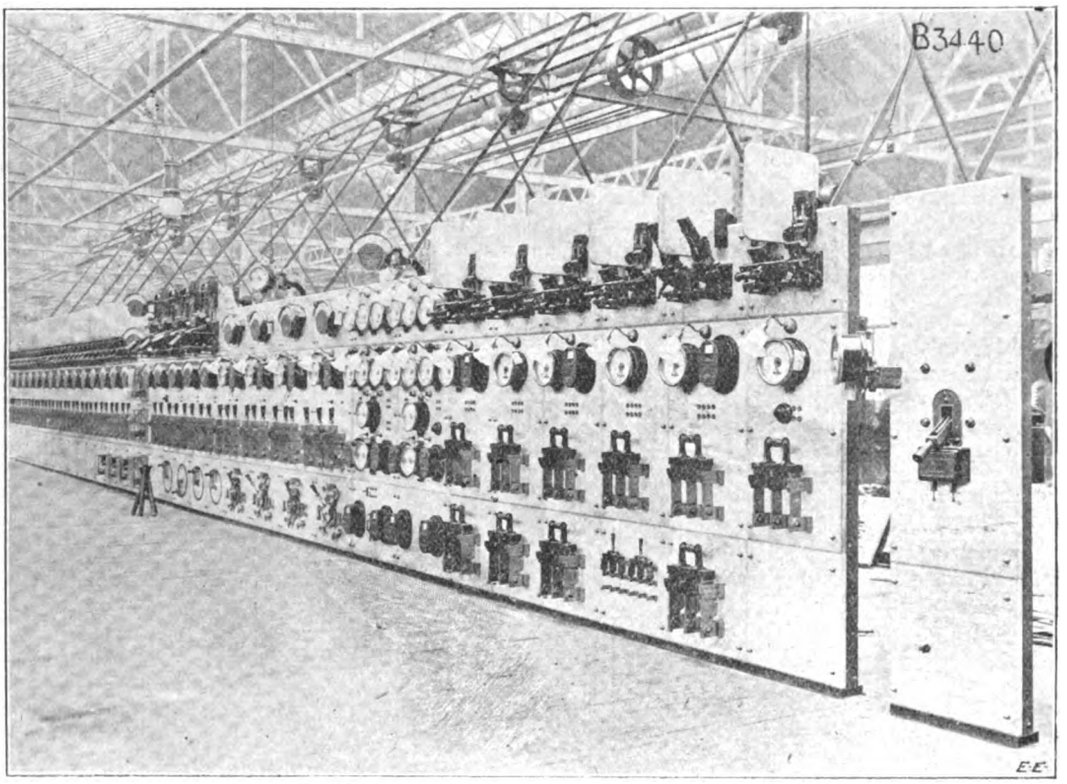

FIG. 16.—View of the Charing Cross Sub-Station Switchboard.

tension lighting panels, which are mounted separately and distinct from the former. The current is transformed down, and then passes through a triple-pole switch and a small separate set of 'bus bars to the low-tension alternate-current 'bus bars, which are divided up into three sections, each

are, firstly, the six alternate-current lighting panels referred to above. Each pair of these contains two double-pole circuit breakers, two ammeters, one integrating wattmeter, two 800-ampere triple-pole knife switches, and one triple pole 1,000-ampere switch for connecting the sub-lighting 'bus

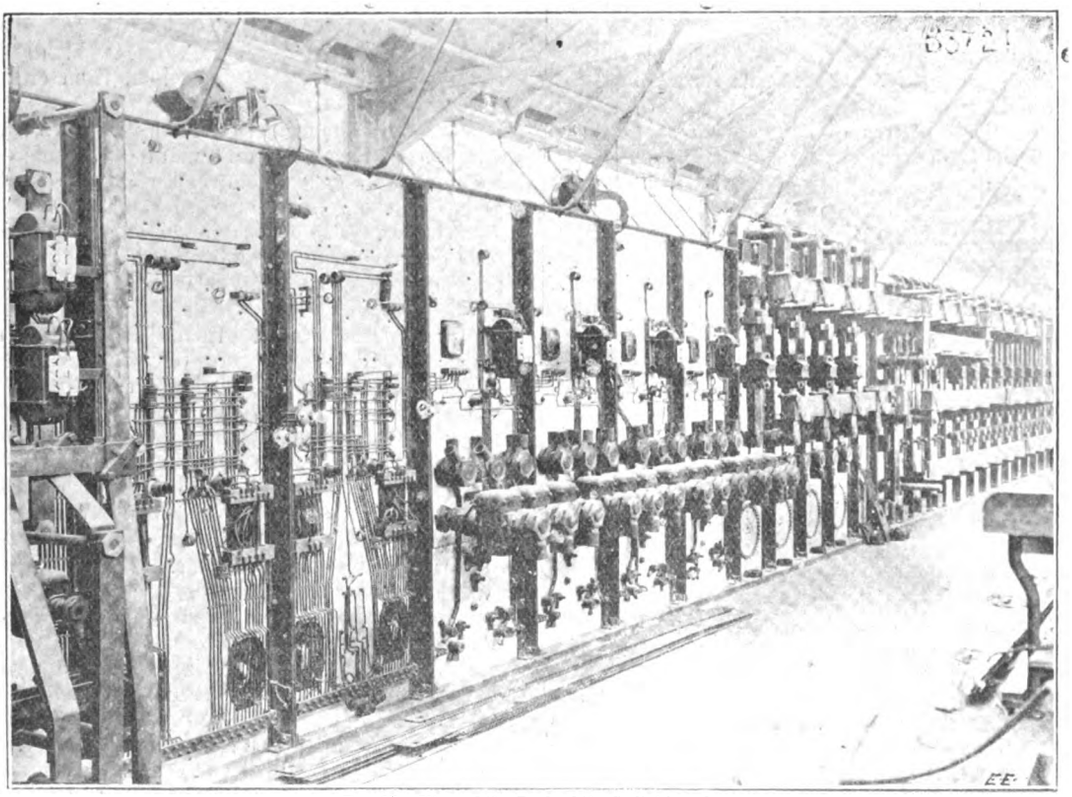

FIG. 17.—View of the Back of the Switchboard.

feeding two lighting circuits. These run in duplicate to the District Railway, the Charing Cross, Euston, and Hampstead Railway, and the Baker-street and Waterloo Railway respectively; and are each provided with integrating wattmeters for measuring their consumption,

bars and the main 'bus bars. There are also two triple-pole two-way 100-ampere switches for starting the fan motors that supply cooling air to the transformers, and one triple-pole main switch for disconnecting the lighting transformer on the low-tension side. The usual swinging arm is

Digitized by Google

attached to these panels, in this case carrying a 300-volt instrument, and plugs and sockets are provided that will

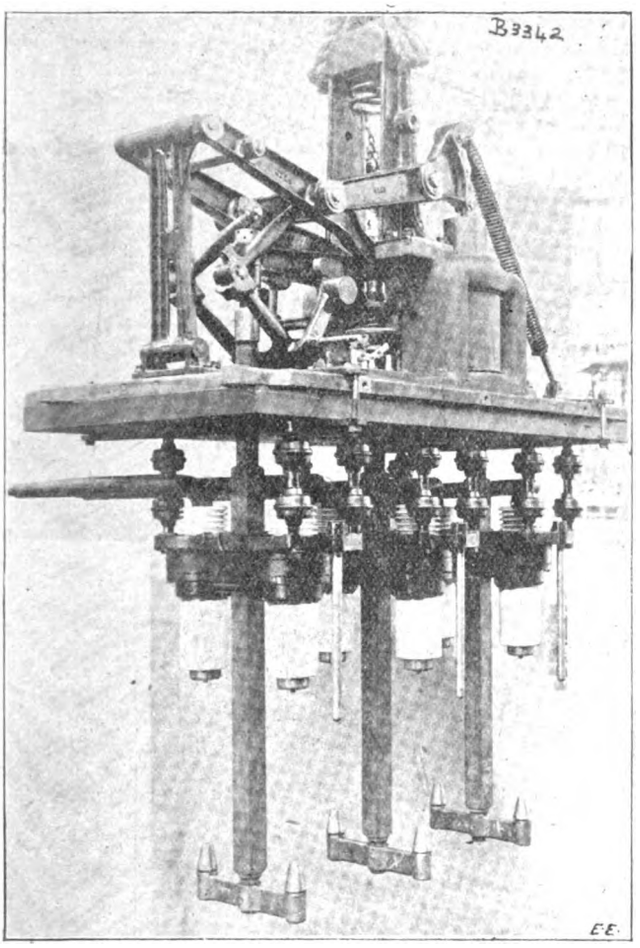

FIG. 18.—The Westinghouse Mechanically-Operated Oil Break Switch for Sub-Station Working.

allow of its connection to any phase and any low-tension feeder for purposes of voltage measurement. The four incoming high-tension feeders are connected, two each, to two instrument panels placed adjacent to the lighting section of the board. These panels are fitted each with six 300-ampere ammeters, two synchroscopes, two integrating wattmeters, and two polyphase reverse-current relays, and adequate illumination of the instruments is obtained by four incandescent bracket fittings. The two red signal lamps below the ammeters are so connected with the two main feeder switches that they will light up, and so warn the attendant, in the event of either of these opening automatically on a fault. These panels also contain two push buttons for tripping the main oil switches and two voltmeter switches, one for each feeder.

Following the feeder section of the board, there are four alternating-current low-tension panels for the rotary converters, each of which contains a large illuminated-dial ammeter, one power factor meter, and one polyphase overload time-limit relay. Red lamps are also fitted and connected with the main switches for the purpose described above. The alternate-current side of the rotary is controlled by three large single-pole knife switches, placed conveniently on the lower portion of the panel, and the sub-base of each contains a starting switch for the induction motor used for starting the converters. Centrally placed above the four panels is a Westinghouse synchroscope, mounted on a double-jointed bracket that enables it to be turned in any direction. The four direct-current panels for the same machines stand next, and contain each, one 4,000-ampere circuit breaker, with a reverse-current relay attachment, one large illuminated-dial ammeter, one voltmeter plug switch, two 4,000-ampere single-pole knife switches, and, on the sub-base, a rheostat dial switch. Then follows the main load panel, upon which are mounted an illuminated-dial voltmeter for the 'bus bars and another similar one for the machines, and an illuminated-dial ammeter that measures the total 'bus-bar current. Next is the wattmeter panel, containing three instruments of 8,000, 6,000, and 4,000 amperes capacity respectively, which are used for metering the power supplied to the three lines before mentioned. The lift panels follow this, three in number, and are each fitted with a suitable wattmeter for measuring the power absorbed by each railway in its lift circuit. After these come 12 train section and track feeder panels, with a capacity each of 3,000 amperes. They are individually fitted as follows: two single-pole. 3,000-ampere circuit breakers, one 4,000-ampere illuminated dial ammeter, and two 3,000-ampere single-pole knife switches; this double-pole arrangement being necessary, as

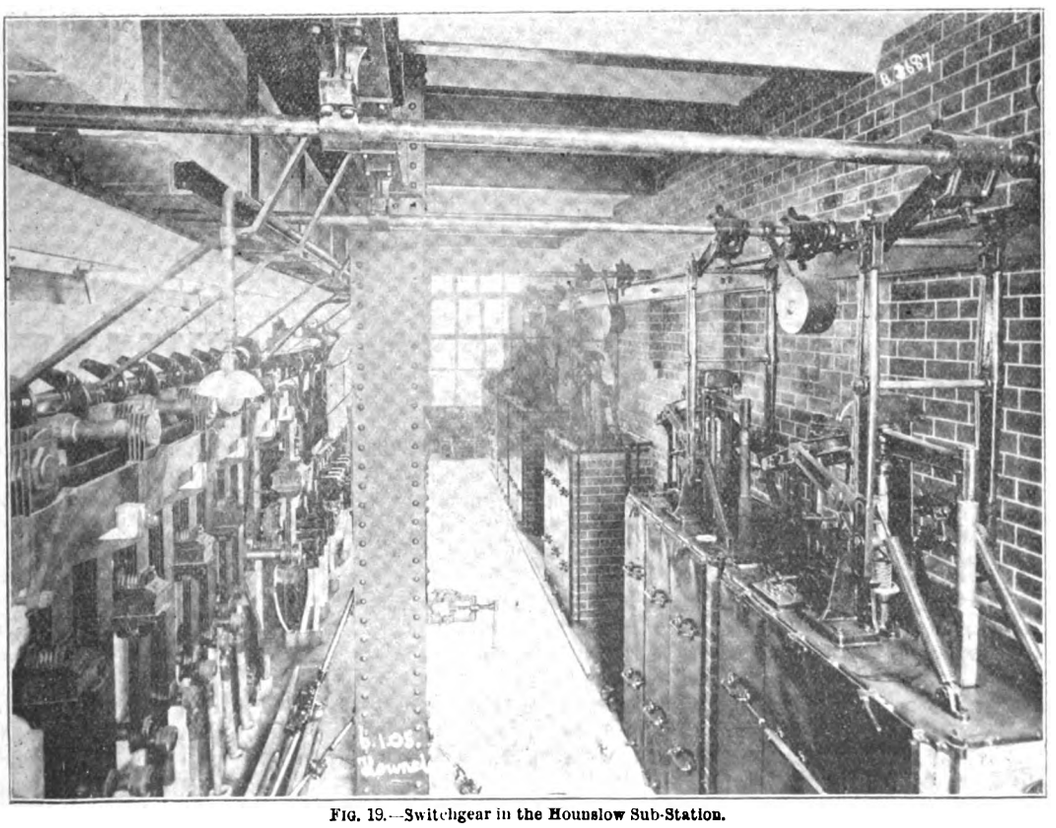

FIG. 19.—Switchgear in the Hounslow Sub-Station.

Digitized by Google

both the positive and negative current rails are insulated from earth throughout. The 'bus bars, which are built up of 6in. by ¼in. copper strip, are arranged with a ventilating space between each section instead of being clamped together solid, as is frequent practice. The small wiring of the switchboards, which so often constitutes a danger, has been very carefully carried out, and is neat and at the same time thoroughly mechanical. The low-tension alternate-current ammeters are all operated by small series transformers, which in themselves are decidedly unique. They consist only of a magnetic circuit and a secondary winding, and all that is necessary is to slip them over the switch studs which form the primary, inducing by the virtue of the current flowing in them the secondary current that operates the instrument. By the arrangement of the whole of the high-tension gear, such as cable ends, series transformers, etc., on an incombustible brick wall divided into small cells, fire and life risks are minimised to a great degree. In similar but horizontal cells the high-tension 'bus bars are placed, and the lightning arresters have each a separate cubicle, with a fireproof door completely isolating them but rendering access easy.

Hand operation is used for all the high-tension oil-break switches (Fig. 18) in the sub-station, and this is effected through gearing by large levers. As before mentioned, they are electrically tripped. The switches are erected in a masonry structure with each of their three poles, and the oil-tank in which they are immersed, in a separate fireproof compartment. Two stationary contacts, mounted in large porcelain insulators, are provided for each pole, one being connected to the incoming lead, and the other to the outgoing. The movable contact, as shown in the illustration, consists of a copper bridge-piece mounted on the end of a strong wooden rod, which latter is fastened at the upper end to a cross-bar common to all three poles. In closing, the magnets mounted on top raise the contacts with the assistance, initially, of a pair of balance springs, and through the agency of a system of levers that give a straight-line motion. The switch is kept closed by a toggle joint, which automatically locks the levers, but upon putting the tripping gear into action, the toggle is released, and gravity, assisted by a powerful spring, causes the cross-bar and contacts to drop to the open position. The oil-tanks, which may be readily disengaged from the contacts, are constructed of heavy sheet metal, and lined internally with an insulating cement moulded to fit closely round the terminals and moving contacts. The amount of oil required and fire risk are thus reduced to a minimum, and the wooden rod carrying the contact piece interposes an effectual barrier between the two terminals of each pole. The tank is fitted with a gauge glass that shows the oil-level at sight, and draining and refilling arrangements are provided that allow the oil to be changed without putting the switch out of service. The small double-pole two-way knife switch mounted on the top of each case is connected in the red lamp indicating circuit above mentioned, and is operated by the movement of the main switch levers, changing its position as the switch moves from "on" to "off," or *vice versâ*. The essential features of this oil-break switch may be shortly summarised as follows: a positive and direct action, the maintenance of the open position by gravity, the immersion of all live parts in oil, high insulation and great freedom from fire and shock risks, and accessibility for cleaning and repair.

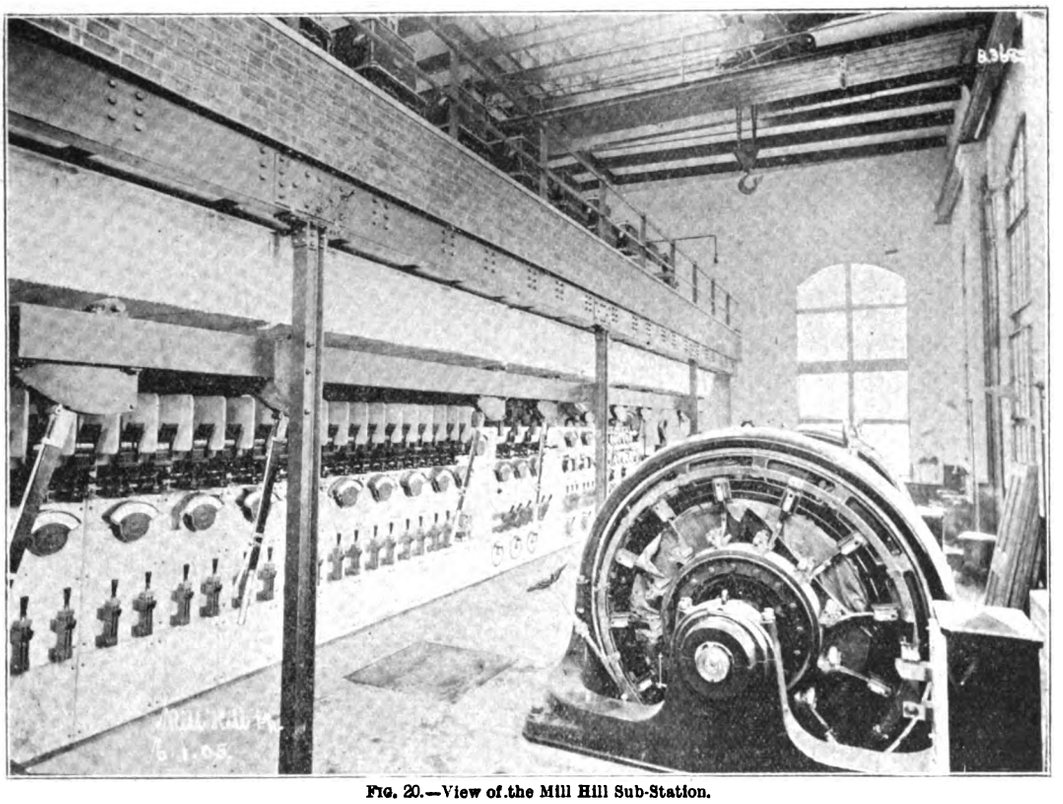

FIG. 20.—View of the Mill Hill Sub-Station.

## AUTOMATIC SIGNALLING ON THE UNDERGROUND.

In anticipation of the more strenuous conditions caused by the shorter headway planned, the District Railway Company has had installed a system of signalling for which great improvements over all earlier systems are claimed. This plant presents features of more than ordinary interest, and is, moreover, the first installation of its kind in this country. The section of line between Hanger-lane Junction and South Harrow has now been worked electrically by the District Railway for over a year, with results that augur well for its success on the more important sections of the line. The length of this trial section is about five miles of double track, and it is divided into block sections varying in length from 1,400ft. to about 3,500ft. On the District Railway generally there are both positive and negative insulated traction rails, the running rails not being used for the traction current. The space between stations is usually divided into two blocks—that is, a "starting" and a "berth" block—and the signalling is on the "normal clear" principle. The signals themselves are of the ordinary mechanical type, and in no way specially adapted for power or automatic working; consequently they are being replaced by special arms with Westinghouse electro-pneumatic signal motors fitted close under them, and the ordinary counterweight abolished for one directly on the signal arm, as shown in Fig. 1. The motors are

Digitized by Google

enclosed in cast-iron casings, and being essentially strong and simple are not affected by climatic conditions. They are controlled by small pin valves worked by means of electromagnets in the local signal circuit. Signal cabins are required only at each end of the branch, or where there

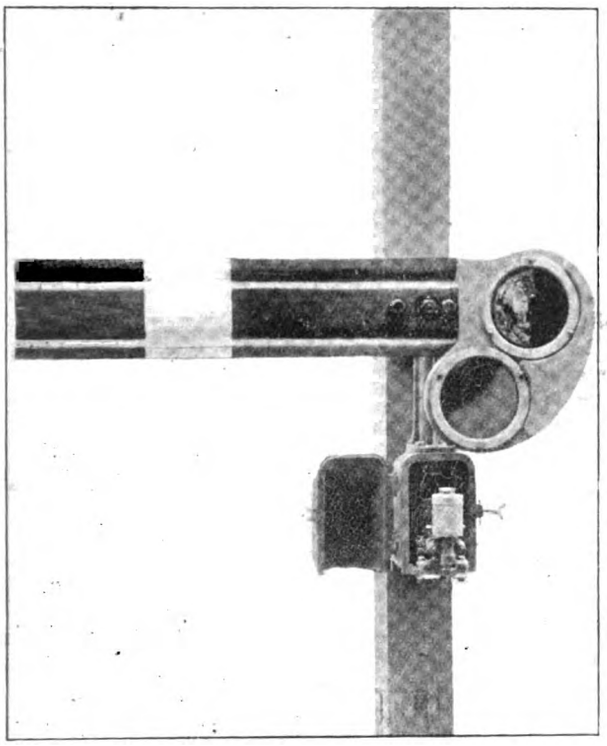

FIG. 1.—An Underground Signal Arm worked on the Westinghouse Electro-Pneumatic System.

is a cross-over road; in the latter case they are normally closed, being opened only when required. An automatic stop (Fig. 2) prevents trains from over-running home signals. This consists of an iron arm between the track rails actuated by a compressed-air motor acting in unison with the adjoining signal motor. When the signal goes to "danger" this arm is elevated to a position in which it engages with a cock on the air-brake system of the train; thus the brakes are instantly and automatically applied if for any reason the driver should run past the signal.

No great saving in first cost need be expected from an automatic installation, as the initial expenditure would probably be quite as great as that incurred in laying down the mechanical system. The working expenses, on the other hand, should be very much reduced, the saving in labour being a most important item, and the cost of renewals and repairs trifling. But, undoubtedly, the greatest advantage of an automatic system is its suitability to the requirements of a very frequent and quick service. The blocks may with facility be made as short as is compatible with the running speed and brake power of the trains. The strain on the signalmen, inseparable from such a service, is abolished, and the safety of passengers is thus independent of the personal equation.

The principles of the system may be best understood by reference to the diagram, Fig. 3. One of the track rails is electrically continuous through the whole length of the plant, and constitutes the positive conductor from the generator to the individual track sections. The other rail is cut up into block sections by means of special rail joints insulated with fibre. All uninsulated rail joints are bonded, to ensure electrical continuity. Power for the operation of the system is generated at 65 volts pressure by motor-generators placed centrally, the negative terminals of which are connected to an insulated negative main running the entire length of the system. This main is connected to each section of the sectionalised track rail at a point near the latter end of the block—*i.e.*, the end at which the train leaves, as distinct from the end at which it enters. It will be seen, then, that there is a potential difference of approximately 65 volts between the continuous positive rail and the insulated negative main. Resistances are interposed in the connections between the negative main and the sectioned rail which reduce the potential difference between the rails to, in the present instance, from three to six volts, according to the length of the block and various local conditions.

Let us now consider the circuit for a single block unoccupied by a train. The current from the positive brush of the dynamo flows along the continuous rail, and thence through the two relays, one at each end of the block, and through the ballast between the rails, all in parallel, to the sectioned rail. From this it flows through a relatively large resistance to the negative main and back to the machine. Now, suppose a train enters the block. Obviously

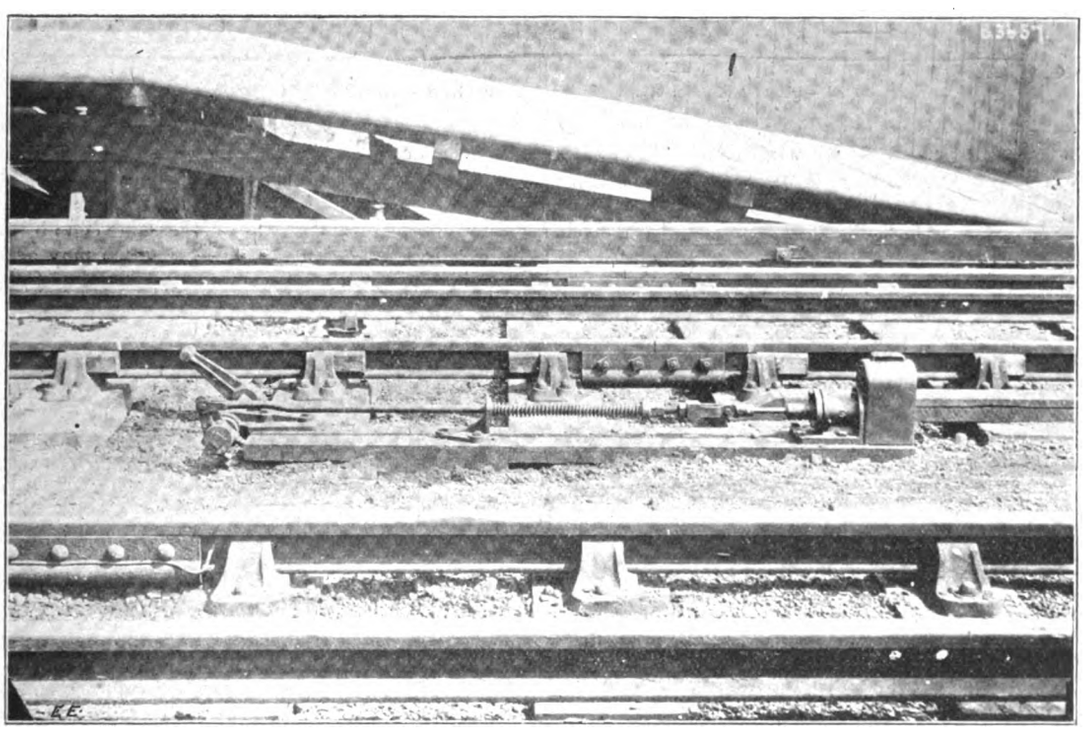

FIG. 2.—Automatic Stop to prevent trains over-running home signals.

the current now flows through the practically negligible resistance of the car wheels and axles from one rail to the other, and the relays are shunted, with the result that the signal is allowed to go to danger. The "track-battery" resistances connected between the negative main and the sections of the sectionalised rail prevent the generator being

Digitized by Google

short-circuited when the track circuit is shunted by the axles of the train. In fact, these resistances bear such a relation to the combined resistance of the road bed from rail to rail and the two relays, all in parallel, that the shunting of the track cuts out only a small percentage of the total resistance of the circuit. Thus the current increase in a circuit, when shunted, is not great. This is important, as it is advisable to keep the track potential as nearly as possible constant. An increase of the total current, resulting from the blocks being occupied by trains, affects the potential between the rails of unoccupied sections, increasing the transmission loss in the negative main. The loss in the continuous track rail may generally be neglected on account of its large section Another circumstance directly affecting this track potential is the variation of the resistance of road bed according to weather conditions. Broken stone forms much the best ballast from an electrical point of view, and cinders the worst. It may here be mentioned, however, that though on several occasions recently the track rails on this system have been flooded, the operation of the signals has, we are informed, been in no wise interrupted.

Next we come to the consideration of the circuits of the track relays which control the signal circuits. Fig. 3 is a diagram of the relay and signal magnet circuits for a single block. The track coils of the relays are permanently connected across the rails at that end of the block at which the relay is placed. Between the pole-pieces a polarised armature is suspended from a pivot. This armature bears a winding of considerable resistance, and is connected between the positive rail and the negative main through a contact—operated by the track-coil armature—which is

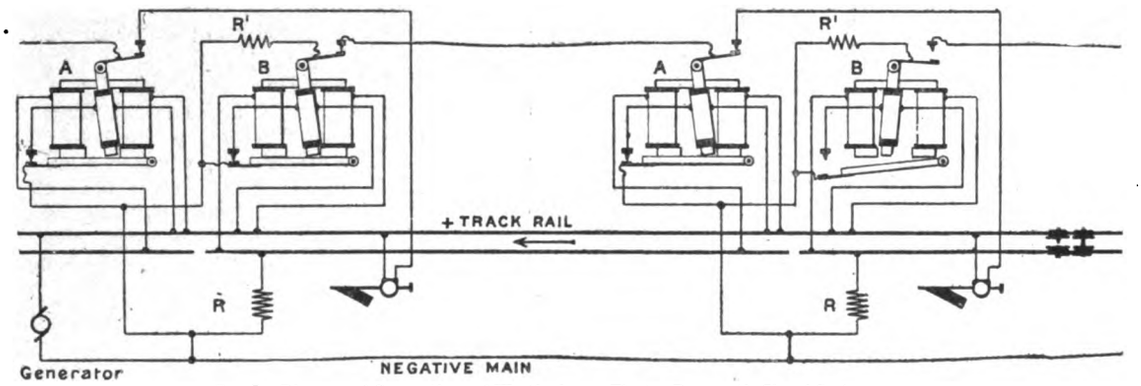

FIG. 3.—Diagram of Connections of Westinghouse Electro-Pneumatic Signal System.

closed when the track coils are energised. To the polarised armature is rigidly connected an arm which actuates a contact, the function of which is to open or close the local circuit controlling the signal motors. The operation of the relays is then as follows: When a difference of potential exists in the normal direction between the rails—*i.e.*, when there is no train on the block—the relay track coils are excited and draw up the armature, which closes the circuit through the polarised armature. The polarised armature is then attracted to one of the poles of the relay, and, swinging over, closes the contact in the local signal circuit. As already mentioned, there are two relays in each block, one at each end. These are duplicates, and operate normally in a precisely similar manner, each working a contact in the local signal circuit. These contacts are in series, as shown clearly in Fig. 3—relays A and B—and unless they are both closed no current can flow through the signal magnet, and the signal will, therefore, remain at "danger" by gravity.

The position of the apparatus when the block is empty has been indicated above: both relays energised, the local signal circuit closed, and the electromagnetic valve operating the pneumatic signal motor consequently open, admitting compressed air to the motor, which holds the signal arm "off." As soon as a train enters the block the relays are short-circuited by the car axles and thereby de-energised, permitting their armatures to drop, and thus breaking the circuit through the polarised armature coils. The polarised armatures then swing back from their position in contact with one of the track-coil pole-pieces, and in doing so break the signal circuit at two points in series. The electromagnet operating the admission and exhaust valves of the pneumatic signal motor is de-energised, and the exhaust is opened, permitting the signal to return to "danger" by gravity. It is, of course, a condition of successful automatic signalling that any interfering influence must, if it has any effect at all, cause the signal arms to go to "danger," and not bring them "off."

So far, so good; but experience has shown that the greatest obstacle to the success of automatic signalling, on electric railways in particular, is the liability of the relays being operated by extraneous currents so as to cause a false "clear" indication when danger should be shown. The particular claim of the system under consideration is that it is impossible for an extraneous current, from whatever source, to bring the signal arm to the "off" position when it should stand at "danger." The main source of extraneous currents affecting the signals is the 500-volt traction power circuit, and when, as is the case at Ealing, the track is not used as a return, the presence on the block sections of current from this source is abnormal. Faulty insulation of the train equipment, positive and negative rails, positive cables, etc., is the most frequent cause of leakage to the track rails. Whether currents other than the signalling current on the track rails are normal, as would be the case were one of the track rails used as a power return, or abnormal, as in the present case, is immaterial; such currents would be equally disastrous to a susceptible system, and are, it is said, impotent to affect the system considered. Faults in the main power circuit occur with sufficient frequency to demand the closest attention on account of the disorganisation of the traffic which they may cause, but even if they were rare, the least liability to give false signal indications of safety would forfeit all claims for consideration.

Although in the present system it is possible for the extraneous currents to energise either one or both relays while the train is in the block, these latter are so interconnected that it is not possible for them both to be energised in the normal direction at the same time by extraneous currents. The various conditions which may occur with a train in the section may be ennumerated as follows: both relays shunted, no extraneous current (normal); one relay shunted, the other energised normally (signal circuit broken at one point); one relay shunted, the other energised reversely (signal circuit broken at two points); both relays energised, one normally and one reversely (signal circuit broken at one point). As will be plainly seen, the circuit through the signal magnet is designed to be always open at one point when a train is in the section, and often at two.

A few words may be added with regard to reliability. The only part of the mechanism which can be described as in any way delicate are the relays, and these are enclosed in weatherproof boxes, where they can readily be examined at intervals. The air pressure used is about 70lb. per square inch, which enables compact motors to be used for signals, points, stops, etc. The air motors employed work, we are told, year in year out without giving the least trouble. The piping is compact, the electrical wires few and small, and the alterations to the track of a trifling nature. The system is applicable where track return is used with either third rail or overhead trolley wire. The signal motors, relays, and other special apparatus were manufactured at the London works of the Westinghouse Brake Company, and supplied direct to the Underground Electric Railways Company of London, Limited, who installed the apparatus themselves.

## ARMATURE WINDINGS OF THE CLOSED-CIRCUIT TYPE.

BY WM. CRAMP.

*(Continued from page 152.)*

**Examples.**

Following these rules, we have for Fig. 11 :

| | |
|---|---|
| Number of inductors ..... | 64 |
| Forward number-pitch ..... | 17 |
| Backward number-pitch ..... | 13 |

The winding table runs :

1——18——5——22——9, etc.

It is curious to note that inductors of each winding come together in pairs around the armature.

As another example of such a winding :

| | |
|---|---|
| Four-pole machine—number of inductors | 228 |
| forward number-pitch ... | 57 |
| backward number-pitch.. | 53 |

The winding table will run :

1——58——5——62——9——66, etc.

Of course, it is obvious that a single *spiral* may consist of any number of turns, and that in the case of slotted armatures the number of conductors must be equal to, or a multiple of, the number of slots.

But inasmuch as the *raison d'être* of a double winding is the impossibility of always being able to get with a single winding as many commutator sections as are necessary for sparkless commutation, it is rare to find a double-wound armature with more than one turn per section. For it must be remembered that, with a given number of armature inductors in a single winding, the maximum possible number of commutator sections is half the number of inductors, and it is only when this number of sections is not sufficient that a double winding (with double the number of commutator sections) is resorted to. Thus, without losing space in a discussion upon the best arrangements for double and triple windings with more than one turn per section, we may pass immediately to the consideration of those armatures in which the re-entrancy is not the same as the number of windings.

**Re-entrancy Independent of the Number of Windings.**

In all the cases so far discussed the re-entrancy has been equal to the number of windings—a double winding was doubly re-entrant, and so forth. We come next to a class slightly different, in which the re-entrancy is not equal to the number of windings.

Take a Gramme-ring armature and place 16 spirals upon it, somewhat like Fig. 1, but let them be spaced so that the distance between spiral 16 and spiral 1 is half the distance between any other two neighbouring spirals: or, in other words, set out with a distance-pitch equal to $\frac{2}{31}$ of the circumference (instead of $\frac{1}{16}$ as in Fig. 1). Then the distance between spiral 16 and half-way between spirals 1 and 2 is also $\frac{2}{31}$ of the circumference ; so that having arrived at 16 the winding naturally continues with the *same pitch* once more around the armature, and then closes at 1. All this is clearly shown in Fig. 12. If we now connect the spirals regularly down to a commutator (as has been done in the previous cases), we find that we have an arrangement which is very closely allied to Fig. 10. Thus in Fig. 12, where this new construction has been carried out, the spirals in series between the two upper brushes are Nos. 1, 2, 3, and 4, and also as a second series in parallel with these spirals *a*, *b*, and *c*. Closer examination will show a similar state of affairs at each of the other brushes.

Note specially that the spirals 1, 2, 3, and 4 are *not* in series with *a*, *b*, and *c*, but in *parallel* with them. Therefore, considering the upper half of the armature alone, between these two upper brushes we have the sum of the electromotive forces due to an average of about $3\frac{1}{2}$ spirals, but the current is due to *two sets* of about $3\frac{1}{2}$ spirals.

As in Fig. 10, so in this case, the fact of these two sets being always in parallel depends on each brush never touching less than two sections ; so that it is clear that the winding is simply another form of double winding, but this time *it is singly re-entrant* (only closes upon itself once), and has *an odd number of spirals*—viz., 31. The voltage is obviously that of a machine having a single winding and $15\frac{1}{2}$ turns on the armature ; but if the winding is of the same sectional area throughout as such a single winding, the current which the machine will carry will be doubled by the use of 31 spirals, provided that the

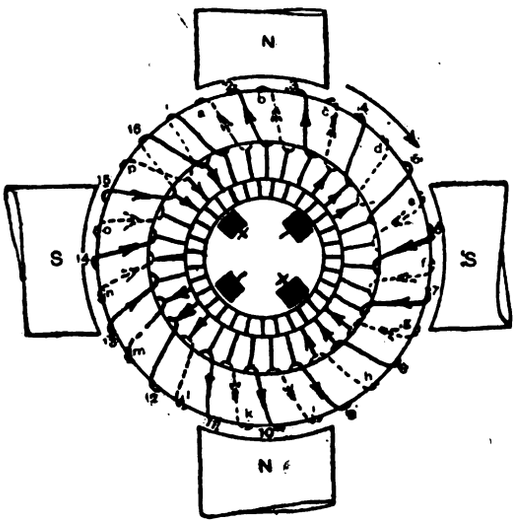

FIG. 12.

brushes are wide enough to make contact with at least two segments of the commutator.

**Reason for the Odd Re-entrancy.**

We may now ask, why it is that this winding is singly re-entrant? It is because *while it has a pitch like a double winding it has also an odd number of spirals*—that is to say, it does not obey in full the first rule of multiplex windings given on page 187. The number of spirals on the armature is *not* a multiple of the number of windings, or, rather, we have a multiplex armature whose windings are not independent ; for a single ring winding with 31 spirals would naturally have a distance-pitch equal to $\frac{1}{31}$ of the circumference, just as the distance-pitch in Fig. 1 is $\frac{1}{16}$ of the circumference. But this 31-spiral winding has a distance-pitch of $\frac{2}{31}$, being, in this respect, similar to Fig. 10, which with 32 spirals has a distance pitch of $\frac{2}{32}$. Like Fig. 10, it has a distance-pitch of a *double* winding, but the number of spirals upon the armature is not divisible by 2.

It thus appears that whether a ring winding is simplex, duplex, or triplex depends simply upon the *pitch chosen* with respect to the *number of spirals*, but the *re-entrancy* is dependent upon the *total number of spirals*. The above winding, for instance, is a double winding, because the distance-pitch is $\frac{2}{31}$, but it is a singly re-entrant winding, because while the distance-pitch is $\frac{2}{31}$, the number of spirals is 31. In the distance-pitch fraction given above—viz., $\frac{2}{31}$—it will be noticed that the numerator gives the number of windings, while the denominator gives the number of spirals.

Digitized by Google

Now, if we follow the first rule given on page 187, the number of spirals should be divisible by the number of windings. Thus, in Fig. 10, the number of windings is 2, the number of spirals 32, and because 2 and 32 have the common factor 2, the winding is doubly re-entrant—that is to say, it may be split up into, or considered as, *two separate single windings of sixteen spirals each*, each with a distance-pitch of $\frac{1}{16}$. From this clearly follows the very important rule: *In a ring armature the G.C.F. of the number of windings and the number of spirals gives the re-entrancy.*

So long as the number of windings upon the armature were entirely independent of each other, there could be no mistake about the meaning of the word "winding" in this connection. But now that we find that an armature may have a double winding *without two independent windings*, some confusion is likely to arise as to the exact meaning to be attached to the word.

In a ring armature we take the definition of a "winding" to be: *A set of spirals placed upon the core permanently in series with one another, and forming one complete annular helix, whether closing upon itself or not.*

With this definition the series of spirals marked 1 to 16 in Fig. 12 is just as much a winding as the series dotted in Fig. 10, although in the former case the particular set of spirals does not close upon itself.

*(To be continued.)*

## DISTANCE-CONTROL SWITCHES AND THEIR LAY-OUT IN STATIONS.

BY W. E. WARRILOW, A.M.I.E.E.

(*Continued from page 119.*)

**Another magnet pull switch somewhat similar to that just described is the distance-controlled switch of the British Westinghouse Company. This is illustrated in Fig. 21, which shows back and front views of the arrangement. As compared with the device just mentioned, a marked difference in the disposition of the terminals and contacts will be noticed. In Fig 20 these are below the bridging contacts and subjected to the weight of whatever oil is in the container, while in Fig. 21 the contacts depend from the supporting base, and the switching or bridging piece hangs below them, the oil-tank being also hung below the contacts, the latter dipping down into the oil. This method, though cramping the connections somewhat at the supporting base, has the advantage of removing one of the weakest spots in the oil container—a terminal at the bottom of the tank in an inaccessible position and subject to leakage of oil. There are, of course, many hundreds of the latter switches in use giving entire satisfaction, but whether oil trouble be responsible for the type or not the latest designs of oil switches, large or small, are fitted with terminals depending into the oil. Referring again to Fig. 21, the two pull magnets will be noticed at the top of the switch. The plungers of these, through chain links and a system of levers, operate the main switch rod, a heavy casting coupling the rods of the three bridging contacts together. The switch is held in the closed position by a pair of toggles, the centre of which is broken by a blow from a tripping magnet when opening the switch.**

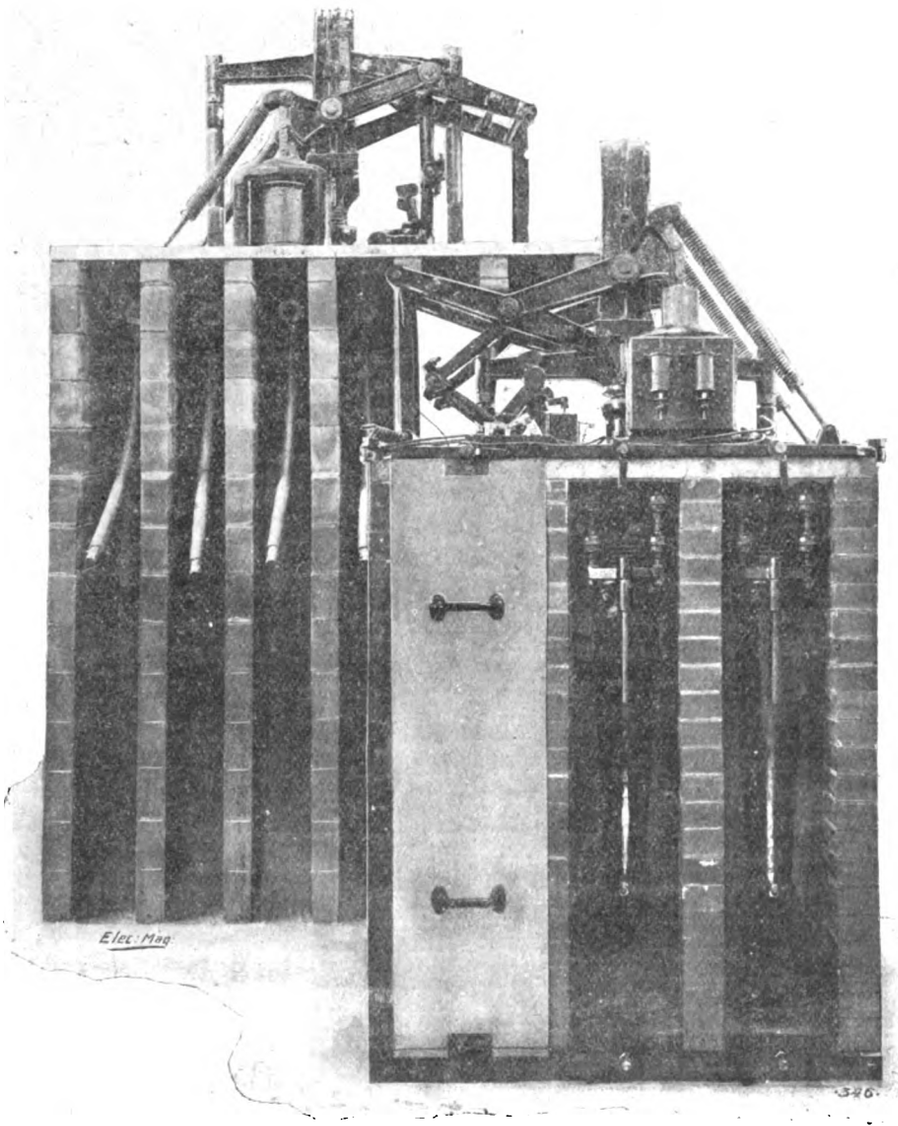

FIG. 21.—Magnet Pull Switch for 33,000 volts (British Westinghouse).

Digitized by Google

The weight of the parts assisted by powerful springs carries the cross-bar and contacts sharply to the off position. A D.P. D.T. switch on the main base is operated by the lever motion in such a way that when the main switch is closed the trip coil is placed in circuit, and when the latter operates to open the switch, the small switch closes a signal lamp circuit on the control table, signifying to the attendant that the circuit breaker has been automatically tripped. When

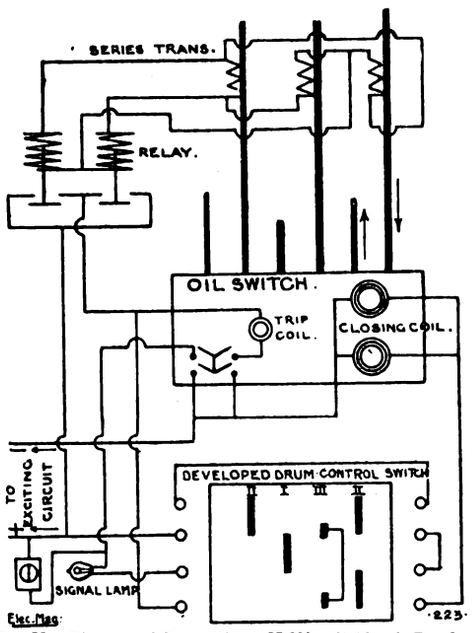

FIG. 22.—Diagram of Connections, 33,000-volt Circuit Breaker.

opened by the attendant the switch does not give this signal. A diagram of the connections is given in Fig. 22. A circuit breaker of the above type is standardised for pressures up to 33,000 volts. Needless to say, the oil-tanks can be lowered to expose the contacts and open up all the vital parts of the switch.

Another design of switch employing pull magnets is illustrated by Fig. 23. It is a type made by Witting, Eborall, and Co., Limited, and will shortly be installed at

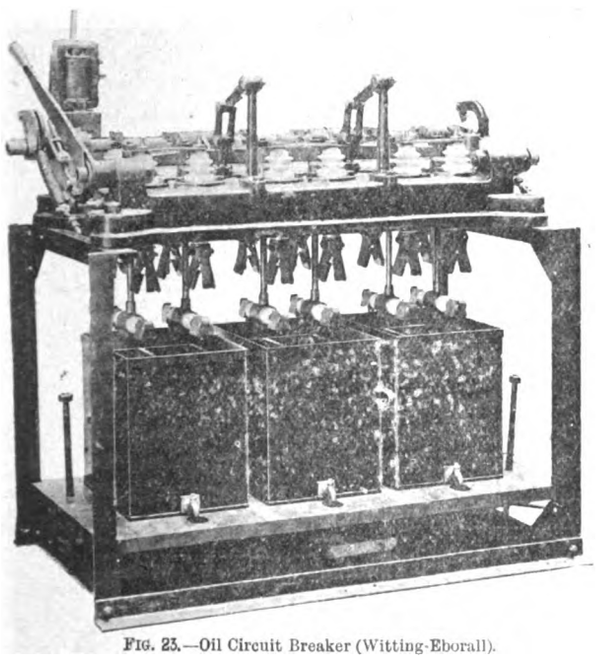

FIG. 23.—Oil Circuit Breaker (Witting-Eborall).

Glasgow and other places. Here, again, the underhung contacts will be noticed and the contact bridges dropping clear into the oil, both fixed and moving contacts being immersed in the oil. The control magnet is mounted at the top of the switch, but is not shown in the illustration, a handle for testing purposes being mounted in its place. There is one tank per phase and two contact bridges per circuit, giving four breaks in series per limb. The switch rods are all coupled to a common cross-head, and at two points equally spaced on this two curved links are pivoted at their centre, their ends being respectively hinged to a swing link fastened to the switch, and a small link and lever fixed to a common crankshaft. The latter runs the length of the complete switch and terminates at one end in a crank suitably connected to the pull magnet. At the other end a smaller crank operates a controller, the functions of which will shortly be referred to. At both ends are powerful springs which assist the action of the switch when being opened. When closed, the shaft is turned and the operating levers are raised, the curved links with swing links drawing up the cross-head and contact bridges. The switch is held in by a catch, which is tripped by an overload or reverse-current device, the solenoid for which can be seen on the left of Fig. 23. The small controller (not shown) performs the following functions: (1) when the switch is closed it breaks the synchronising circuit, thus removing the load of the lamps and synchroscope from the synchronising transformers; (2) it breaks the tripping magnet circuit when the switch is opened, the spark which would otherwise form on the relay contacts thus taking place at the controller; (3) it closes the signal lamp circuits when the switch is closed. For a feeder circuit the controller is, of course, much simpler. A small two-way switch on the operating panel is used to open and close the main circuit breaker. When thrown in one direction it closes the pull-magnet circuit, while in the opposite direction it energises the tripping coil. When released from either position the switch flies to central off position, and thus entirely prevents either circuit being left permanently closed. The oil-tanks of this switch are teak lined, and divided by marble slabs into two parts for the different breaks for each pole, a separate tank per phase being provided. The tanks can be raised and lowered simultaneously for inspection of contacts, oil renewal, etc., and the entire switch is made to slide on rails to render withdrawal easy. Such a switch will control successfully a 3,000-kw. circuit, and break a circuit many times in excess of this if needed. It can be used for the parallel operation of generators of the above size.

*(To be continued.)*

## STUDENTS' WORK IN PLANNING CENTRAL STATIONS.

BY E KILBURN SCOTT, A.M.I.C.E., M.I.E.E.

It occurred to the writer that it would be good exercise for the senior students at the Northampton Institute to plan out a central station. The information given to them was: length and width of engine and boiler house, 100ft. by 50ft. each; approximate size and duty of a Babcock boiler, 16ft. by 23ft.; the number of tubes of a Green's economiser; the output and size of a slow-running single-crank tandem compound engine driving a multipolar traction generator; the internal diameter of a steel chimney, 7ft.; also the information that the coal was to be dumped at one end of the power-house, and carried by a spiral conveyor along the front of the boilers for hand firing.

The students were required to get into the space available as much plant as it could conveniently hold, taking into consideration all questions of lighting, positions of doorways, gangways between the various units, suitable spacing for condensers and other auxiliaries, and proper position for the chimney with a view to shortening the flue, and, in fact, all the various points which must be taken into account when such a station is laid out in an engineer's drawing office. They were also required to fix the relative positions of the dynamos and switchboard, with a view to the easy operation of same, and for economy and convenience in the connecting cables.

Figs. 1 to 3 show the result of about 1½ hour's work by various students, and it is interesting to see how they have arrived at different arrangements, each of which may be said to be a reasonable solution. The spacing of the pieces of machinery was done in the usual manner by cutting out pieces of paper to size and moving them about until the proper distances had been arrived at.

Digitized by Google

There are many examples like this which might be set to students in colleges, polytechnics, etc. For example, one very good test would be to give the students a patent specification to draft on some improvement or other detail of, say, a dynamo machine. The question of whether it was a patent or not would not affect the matter so very much, but the practice would be extremely valuable. In the case of colleges or day classes it might include a certain amount of searching and a report on existing patents for a year or so. Of course, in order to enable them to set about the work, the lecturer should first give them a short description of how to properly go about it, and also supply each student with a sample specification of some similar patent.

## TIME-LIMIT RELAYS.

There is an increasing demand in an automatic circuit breaker for the introduction of a time element in its operation. Various methods of attaining this end have been tried, nearly all of which fail to conform with all the requirements of such apparatus. The timing device should,

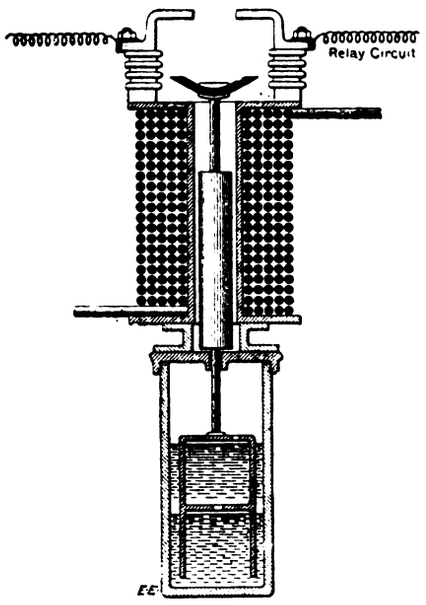

FIG. 1.

as far as possible, fulfil the following conditions: (1) the time element should be adjustable; (2) the time element should vary as nearly as possible inversely as the excess load; (3) the mechanism should return instantly to its zero position when a temporary overload is reduced to the normal load; (4) the relay should instantly trip the breaker upon the occurrence of a dead short (except in special

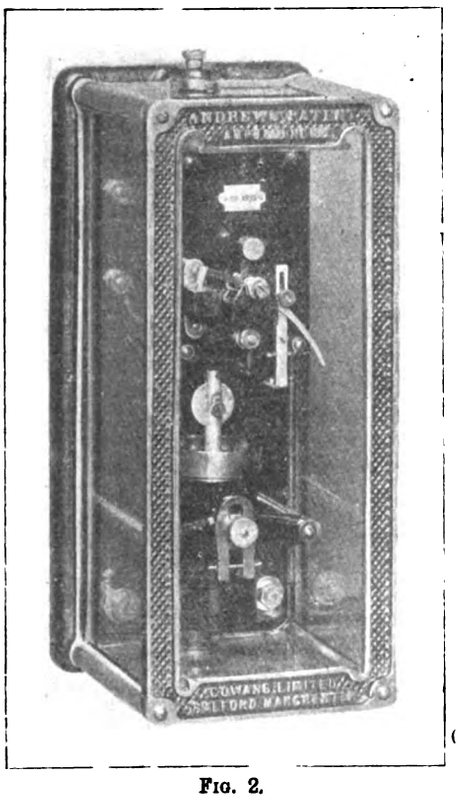

FIG. 2.

cases); (5) it is preferable that the relay shall be so designed that no attention is required for winding mechanism, etc.; (6) it should be simple in its action, and not materially add to the cost of the circuit breaker.

The time-element device illustrated and described below was designed by Mr. L. Andrews, and is manufactured by Messrs. Cowans, Limited, of Salford, Manchester. Mr. Andrews has attempted to conform, in his instrument, to the conditions enumerated above. Its action will be best understood by reference to Fig. 1. The speed at which the core is lifted within the solenoid is controlled by a diving bell immersed in mercury and oil. If the core is subjected to a small pull sufficient only to raise its weight together with the bell, it will rise very slowly, because the tendency for a vacuum to form within the bell will result in the mercury contained in its lower half being lifted. The weight thus added, which checks the upward movement, would, unless special provision were made, bring it to a standstill. The pressure of the atmosphere, however, relieves the vacuum by forcing the oil in the upper half of the bell through the small hole in the middle diaphragm, and the rate at which it does so determines the time taken by the core to travel from its zero position to the position at which it closes a local circuit, and trips the breaker. It will be obvious that the time will approximately depend upon the strength of the pull on the one hand, and the dimensions of the oil inlet on the other. In the event of a dead short-circuit, the mercury contained in the bell is raised bodily, and the action of the instrument is instantaneous.

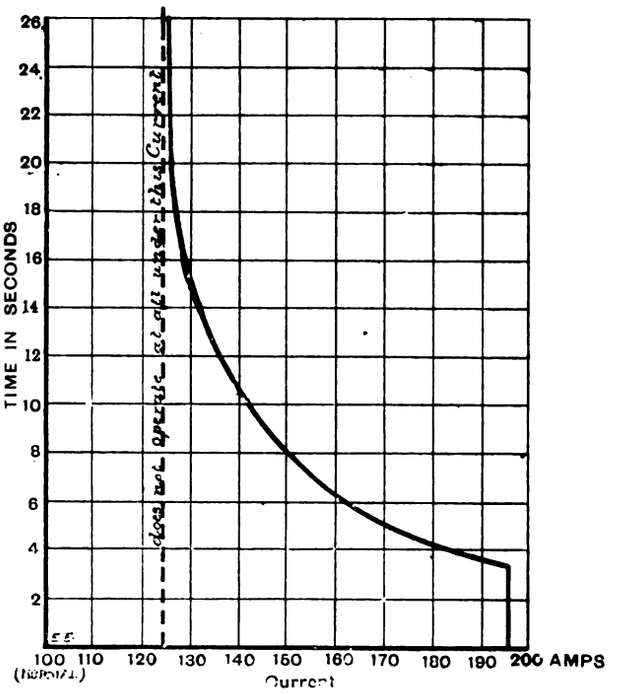

FIG. 3.

Fig. 2 shows one of 70 odd instruments supplied to the Bristol Corporation for their new switchboards. It will be seen that the mechanism is contained in a glass case, which has the advantage of keeping its working parts under easy observation. In these instruments the area of the oil inlet is varied by means of a coned valve, which is easily adjusted by means of an eccentric aluminium disc. A large range of time element can in this way be obtained from a fraction of a section to 20, 30, or more seconds.

Fig. 3 shows a curve which has been plotted from some experiments made upon one of these relays. In this curve the abscissæ denote the currents, and the ordinates the time. It will be seen that when the current reaches a certain maximum the instrument acts instantaneously. In certain cases this feature is not required, a time element being desired under the severest overload. Mr. Andrews has arranged that in these cases an additional disc shall be used which is immersed in the oil, and by its dash-pot action retards the movement under the strongest pull.

---

MACHINE-TOOL ACCESSORIES.—Messrs. Edward G. Herbert, Limited, Rosamund-street East, Manchester, have sent us particulars of their Vee cramps and blocks, also of their box jigs. By the use of the latter holes can be drilled or surfaces machined on five different sides of an object at one setting. Besides saving a number of settings, this ensures that all the holes and surfaces are square or parallel to each other.

## GUERNSEY TELEPHONY.

These are the more or less stormy days of telephony, when nothing is really settled and when everybody wonders what next. A triumvirate pulls the strings—there is a company with a virtual monopoly over nineteen-twentieths of the country; there is the Government on its trial in two or three places; and then there are the half a dozen or so municipalities also on trial. The victor, if victor there is to be, is hidden in the mists of futurity. All that we can do is to try and make the position clear—to indicate each step, whether retrograde or in advance. It is nearly twelve months since we commented upon the annual balance-sheet of the Guernsey telephones—to be exact, in fact, on March 11, 1904. We then rather hinted a challenge, which was accepted, to pick holes in the published accounts. The weak points were suggested, but they seemed such frivolous criticisms that no reply was needed. The system has now passed through its seventh year of working. The accounts of that year are published, and are open to comment. To us they seem as favourable as did the earlier accounts, and the concern seems to be in a flourishing condition. The prime question in every concern is, does it pay? Of course, we assume there is no faking of figures. In the first place, we will follow the method adopted last March. Then the engineer gave the cost per line as $\frac{21,262}{1,217}$ = £17. 9s. 5d. per line. Reckoning in the same manner, at the end of 1904 the figures read $\frac{23,590}{1,375}$ = £17. 3s. 3d. per line. But one critic objected to the method of computation adopted—which was,

$$\frac{\text{cost works completed and under construction}}{\text{total number of lines}}$$

arguing, firstly, that cost of land and buildings should be included in the cost. The argument against this course is forcible, but really the sum—less than £3,000—is so inconsiderable that it might be included, and we get $\frac{26,475}{1,375}$ = £19. 5s. 1d. per line. We take total number of lines, not the lines the critic termed revenue earning. Every line, be it service or sundry, indirectly assists in earning revenue, and has to be paid for to construct, and has to be provided for in depreciation. Oh, this word! Of course, the critic at once hinted that "if the depreciation fund were 7½ per cent. instead of 5 per cent.," the net profit would be turned into a loss. He forgot to say that the 5 per cent. is only one item in the depreciation, and that the real depreciation is much more. In the first place, the item reserve, depreciation, etc., 5 per cent., is exclusive of interest on capital; then amounts are written off tools and furniture accounts; then the balance profit is added to a second reserve account. The capital advanced by the States is £27,587, which, with the reserve (£5,768) and creditors (£68), brings the liabilities to £33,423 (odd shillings left out). The reserve funds increased during the year from £4,227 to £5,768, so that the reserve is over 20 per cent. of the capital. The revenue during the year was £4,546, against £4,064 last year—an increase of nearly £500. The expenditure, including interest and amount written off, tools and furniture accounts, was £3,005, against £2,709 last year—an increase of £300. The revenue per line was, in 1903, £3. 6s. 9½d., but it decreased in 1904 to £3. 6s. 1d. It is extremely interesting to watch these annual balance-sheets, and this decrease per line will need careful attention to find a cause and obtain a remedy. We quite agree with the critic to whom we have referred to above, that real comparison is impossible between what rules at Guernsey and the necessities

Digitized by Google

of a British city, but the results of the working can be used to advantage by allowing for the variant conditions.

To jump from Guernsey to America may be permissible when telephony is in question. Last week our interviewer gave Mr. Hesketh's opinions upon American telephony. They were altogether good. On Tuesday the *Globe* says of New York telephony, "It is contended that the service is not only monstrously expensive, but inefficient into the bargain." Where doctors differ, who shall decide?

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### ALUMINIUM.

SIR,—Will you allow me to add a few words to this question, as I fail to understand Mr. W. Smith's explanation. The resistance of a conductor varies directly as its length and indirectly as its cross-section. If we increase the length in a certain ratio, and wish to keep the resistance constant, we must also increase the section in the *same* ratio. In the case under consideration the leakage current flows radially through the insulation. The length is represented by the thickness of the insulation, the cross-section by the cylinder, having as diameter the mean diameter of the insulation. Supposing the thickness to be 1 for copper and 1·3 for aluminium, then the mean insulation diameters (and consequently the circumferences) will have the same ratio, and the insulation resistances will be the same in both cases. Mr. W. Smith in his paper might have been thinking of the quantities of insulation, in which case he would be right, but the thicknesses are certainly in the ratio 1 : 1·3 —Yours, etc., R. T.

### THE METRIC FALLACY.

SIR,—With your permission I should like to refer to two or three points in the letter of Mr. Dale which appeared in your issue of the 3rd inst.

With regard to my statement that in the United States the yard is derived from the metre and the pound from the kilogramme, my authority is the Director of the National Bureau of Standards at Washington. Mr. Dale quotes Lamoitier in connection with the anarchy existing in the textile trade through the confusion of weights and measures. I should like to say that M. Paul Lamoitier is anxious to see the metric count of yarns adopted as an international one. Without professing any technical knowledge of the application of the count, it is certainly not evident that the use of the present, or a metrical, count is in any way regulated by the existing laws in France relating to weights and measures.

One moment's thoughtful consideration would convince any of your readers that the number of threads of silk in a given weight of the twisted material is not a matter which has been brought within the scope of any Weights and Measures Act in any country. The whole of Mr. Dale's contention about the unsuitability of the metric system for textiles is just as wide of the point as if he had claimed that the metric system was unsuitable to the publishers' trade because he had found a number of books where the pages did not number out to an even decimal number, or because the measurements of the books were not precise metric measurements.

The fact that there is a desire to adopt a metric count for yarns show that there is in the yarn trade a number of merchants and manufacturers who think it would be a means of securing international uniformity in the numbering of yarns. Mr. Rowlett's letter of Jan. 20 bearing on this point makes the attitude of the textile trade towards the metric system tolerably clear.

Mr. Dale quotes from John Quincy Adams on the subject of useful proportions in our weights and measures, but as his quotation refers to the American ton of 2,000lb. we lose some of the usefulness. Of course, it is perfectly well known that a relation exists between our weights and measures—it would be impossible to invent a system without one; but it can hardly be argued that the relationship in the British system—viz., a cubic foot of water weighs 1,000oz.—can compare for simplicity of manipulation with the corresponding relationship in the metric system, where one cubic centimetre of water weighs 1 grm.

I am happy to accept Mr. Dale's correction in regard to the size of the American gallon; it will make no difference to the argument.

With regard to the survival of "customary" British standards, I think Mr. Dale misapprehends the point. The survival of old French standards has been adduced by others as an argument against the *merits*, not the *introduction* of the metric system, and I ask if similarly the survival of "customary" measures in this country is to be taken as detracting from the merits of the British system?

Mr. Dale makes light of the chaos that exists at present in our weights and measures, but there is ample evidence that advantage is taken of this confusion by dishonest traders. Mr. S. Wallace, M.P., informed the Select Committee of 1895 that there had been many financial disasters in 1894 to people who bought Canadian hay in tons of 2,000lb., purchasers thinking that they were buying at 2,240lb. to the ton. Within the last few days, a correspondent has informed me that an English firm of pump-makers found their chief competitor to be from America, "which has an old gallon weighing about 8½lb., and *consequently their pumps appear to give* more gallons than ours" We should hardly expect to find the American pump-makers in question anxious to have a similar gallon to ours.

Mr. Dale's concluding sentences are interesting. "America is with you in language, common law, weights and measures." Well, we are not dealing with language, or common law, but his own letter supplies evidence that America is no longer with us in weights and measures. He admits a different bushel and gallon, and I might now instance our stone and hundredweight. And one wonders whether, in the question of coinage, America sold any part of her birthright for what Mr. Dale might call a "mess" of decimal or any other kind of "pottage."—Yours, etc.,

E. JOHNSON, Secretary, Decimal Association.

SIR,—In your issue of Jan. 20, Mr. Rowlett, of the Comité permanent des Congrès internationale de 1900 pour l'unification de numérotage des fils, states that the "chief reason why the metric system in numbering yarns has not been universally adopted, is that Great Britain has refused to agree." In addition to the English system, which is the single standard for linen, and the metric system, which is used to a limited extent for wool, the French use 10 different systems of numbering yarn They are the Roubaix, Fourmies, Elbœuf (three), Reims, Sedan, Vienne, worsted, and cotton methods. All of them originated in France, and have persisted in spite of every effort by the French Government and people for more than a century to eradicate them.

On what theory is Great Britain responsible for this anarchy of French standards? Why has not France abolished these standards and adopted the metric system? The French decree of 1810, making the metric system the standard for linen, hemp, and wool, is still in force. Why do the French not obey it? Is Great Britain to blame for that violation of French law?

Mr. Rowlett says that "one result of the congress of 1900 at Paris has been the adoption by users and makers of raw and thrown silks, including the Silk Association of Great Britain and Ireland, of the metric numbering of silk for international purposes." The French decree of 1866 provided for a gramme-500 metre standard for silk. It has been a dead letter from the date of its passage. The Paris Congress of 1900 adopted the Italian system of numbering silk with a basis of 9 instead of 10, and actually called it decimal and metric. The Comité permanent des Congrès international de 1900, of which Mr. Rowlett is a member, has since repudiated this action of the congress, and adopted a fixed weight system of 1,000m. per kilogramme for silk, in opposition to the universal fixed length method of the silk trade.

Can Mr. Rowlett name a single silk mill in the entire

Digitized by Google

world that has changed its *denier-aune* system because of these various resolutions? Can he tell us what the metric system of numbering silk is?

If the French will not obey the law of France, how can we expect the resolutions of the Paris Congress or its Comité permanent to be obeyed by the textile trade of the world?

Mr. Rowlett advocates the metric system "in the interests of the simplification of education," doubtless referring to the well-known claim that the introduction of the metric system would save from one to three years in the school life of every child. I would like him to reconcile that claim with the fact as disclosed by the Board of Education of New York that only 34½ weeks of the eight years of school attendance is occupied with mathematics, and that of this time 20 per cent., or only $6\frac{8}{10}$ weeks, is devoted to compound numbers, weights, and measures.—Yours, etc.,

Boston, Mass., Feb. 4, 1905. SAMUEL S. DALE.

## TELEPHONE RATES.

SIR,—In a spirit of extreme weakness I take up my pen again. Your stern reproofs I admit are not wholly undeserved. Some of my remarks were certainly frivolous. But when people become personal, I have a tendency to become frivolous. If you will blue-pencil the personalities, I will abstain from harmless frivolity. In that way controversy may be shorn of its jagged angles, and the path to truth made easy.

You will pardon my insistence, but I am not content to be contradicted on a question of fact. The third paragraph on p 26 of the *Electrical Engineer* clearly shows that the argument was that a rate of £5. 10s., or between £5 and £6, is the proper thing for this country, and that the whole business must be judged in advance by such a figure. Therefore, £5. 10s. was the pivot of the argument, and was not merely assumed for the sake of illustration. Perhaps you will kindly reprint that part of the paragraph which contains the figures, beginning "The people's part" and ending "compulsorily by arbitration," so that your readers may see clearly who is right on the question of interpretation.

Mr. John Macfee is commendably brief. Wishing to avoid the harsh language apparently inseparable even from a 10-line letter contributed by a municipal telephonist, I can hardly be so brief in reply. Mr. Macfee says that "no rebuilding of plant will be necessary." I have had some little experience of the work required to be done in converting a large telephone system from one method of working to another, and I beg to differ. When Mr. Macfee has got a little further with the work of converting the Glasgow system, he will doubtless find reason to modify his very positive statement. My letter published in your issue of Jan. 20 was based on an official announcement in the Glasgow Press, which stated that the whole Glasgow Corporation telephone system was to be converted to an improved method of working, the method described being what is generally known as the common battery system. As a telephone man of some experience I know that such a conversion can only be carried out effectively by means of a complete rebuilding of the plant, involving new central office and sub-station equipment, and, in the case of Glasgow, probably extensive alterations to the cable plant. Evidently the Glasgow Telephone Committee and Mr. Macfee think differently, and are thinking of grafting relays and lamps on to the present call-wire equipment. I give them a friendly warning that if they proceed on those lines, their last state will be worse than their first.

Mr. Macfee considers my remarks as to the probable cost of an effective conversion and to the telephone muddle at Glasgow to be the outcome of a prejudiced imagination, and too ridiculous for comment. The only prejudices aroused in my imagination by the telephone work at Glasgow are due to the badness of that work, and to the disingenuous arguments and inaccurate statements which have from time to time been made in support of it. There was absolutely no excuse for providing Glasgow, in 1900, with a telephone system which was obsolete in every respect. In spite of the fact that that system was 10 years behind the times in all its essential features, those chiefly interested in it have, up to quite lately, repeatedly claimed that it was all that was modern and up-to-date. Under these circumstances a "prejudiced imagination" in one who knows the real facts is not altogether inexcusable.

Now, what are the facts as to telephone muddle and probable cost of conversion? According to the published descriptions, the Glasgow Corporation telephone system contains 20 exchanges. Of these, five are equipped with flat call-wire switchboards, 14 with vertical magnetic switchboards, and one with a vertical board having signals arranged for push-button calling and clearing. The public stations in the main exchange district are worked from a separate switchboard. At some of the smaller call-wire exchanges ring-off indicators have been added to the equipment, so that calling-off may be done without speaking on the call-wire. The new exchange opened last year is within gunshot of the main exchange, originally designed to serve 10,000 lines, and actually serving only between 5,000 and 6,000. The new exchange is on a totally different system from the main exchange, though it serves part of the same district. There are five different methods of working the service from the subscriber's station in vogue, and the whole service is worked on what is called the "ring-through" system, the subscribers ringing each other up. The subscriber's list contains an appalling number of notices to subscribers, telling them what to do and what not to do in working the service, both generally and in certain districts. The cable plant is laid out for taper distribution, involving a tangled collection, not merely of Y-joints, but of what might be called "octopus" joints, and the complication is increased by the distribution of the call-wire circuits. More than a third of the total length of cable in use is armoured cable, buried solid in the ground.

This is a brief description of a telephone system built all within the past 4½ years. Honestly, I do not think the term "telephone muddle" is too harsh a term to apply. However, if any telephone engineer (British municipal telephone men barred), British, Continental, or American, will state in your columns that it is not a muddle, that the above paragraph describes such work as he himself would have done, starting in 1900 to build a telephone system in a city area of a million population, then I will cheerfully withdraw the word.

Of the advisability of completely reconstructing the Glasgow Corporation telephone plant there can be little doubt. In fact, if the plant is to be put into condition to give a modern service and to be developed along right lines, it is an absolutely necessary step. I offer Mr. Macfee and the Glasgow Telephone Committee that advice free. A detailed report and estimate I should have to charge for, but I should be much surprised if the cost of such an effective reconstruction as is necessary came to much less than the approximate estimate I gave on Jan. 20. In this Mr. Bennett would doubtless agree, as he thinks that the Post Office will have to spend quite as much as they may pay for the National plant in bringing it up to date. Most of the National plant, though some of it is of older date, is more modern in type and more efficient than that of the Glasgow Corporation telephone system.—Yours, etc.,

HERBERT LAWS WEBB.

35, Old Queen-street, S.W., Feb. 6, 1905.

SIR,—I see that Mr. Laws Webb admits in your current issue that he is an employé of the National Telephone Company, with a special mission in connection with municipal telephones. So long as this is publicly admitted I have no objection to his doing his best—that is to say, by *honourable* and straightforward means—to stay the progress of municipal telephones in the interests of his employers, but I do object to anybody in such a position posing as an independent consulting engineer, expert, or critic, and I do object to underhand methods in every shape and form.

The only other point in Mr. Webb's long effusion that I need notice is his statement that while the corporations only gained 4,687 stations in 1904, the National systems in the same places gained 8,074. It is necessary to note that while the correctness of the corporation figures can in every case be checked by any ratepayer who likes to

Digitized by Google

take the trouble to inspect the books, there is no guarantee whatever that the National Company's figures are anything but imaginary. For a long time past that company has been claiming an enormous increase in subscribers in Glasgow and other places, but this claim has not been substantiated by their published directories—a fact which has been several times pointed out in Glasgow, where the company has been challenged (of course, in vain) to support its assertions by showing its books. I submit, therefore, that the two sets of figures do not stand on the same basis as regards credibility. It is possible that the National Company has obtained a larger number of additions in Glasgow and elsewhere during the past year than the corporations, but that has only been done by pushing telephones at 25s. a year, party lines, omnibus lines, and other cheap and inefficient odds-and-ends which the municipalities disdain to touch. In every case the corporation exchanges consist mainly of direct exclusive lines, and it is these which constitute the backbone and bulwark of a telephone system. In Glasgow the Corporation have over 2,000 more direct lines than the company. The corporations also adhere strictly to their tariff rates, which are remunerative; the company confessedly elects to run at a loss. Under such circumstances, corporation systems can only subsist by supplying a superior article which it pays people to take at a higher price, and it speaks much for their vitality and recognised usefulness that they continue to expand in the face of such indiscriminate opposition.—Yours, etc.,

A. R. BENNETT.

[We insert these letters, but *here the correspondence must stop*, as it leads to no advance. Just a short reference to each letter. We reprint, as desired by Mr. Webb, the paragraph *re* £5. 10s.*, merely remarking that Mr. Bennett's argument is to establish a basis to guide the Government as to the maximum it should pay in purchasing the telephones. Naturally, he takes rates found to be remunerative, and says, "There's your factor, your guide, the maximum rate you should contemplate in your purchase." Had the remunerative rates been others, he must have used other figures. There is no dispute with Mr. Webb as to a question of fact—the £5. 10s. is a fact—provided by the remunerative rates. What Mr. Webb does not see or does not admit is that supposing the remunerative rates had been others, not £5 to £6, Mr. Bennett would then have used the mean of the other rates to show the factor controlling the limit of purchase money. Everybody uses similar methods in every business transaction throughout the entire world. Do you want to know the price of a cow? You naturally seek to know the prices generally given, and fix your own accordingly. Mr. Webb himself uses similar methods of argument when he says, or implies, all the modern telephone engineers, except Mr. Bennett, prefer the common battery system, and wants us to infer, what is probably correct, that the experience of the majority is a better guide than the experience of the unit.

Mr. Bennett's letter weakens his case. To the general public each telephone installed is a different station, and if a man gets what he wants he does not care a pin whether it is by means of a party line or any other line. The two opponents each hold the opposing system to be inefficient, and have given general or specific reasons for such inefficiency. Surely Mr. Bennett should stick to his guns. He is proud—deservedly so—of Guernsey, but in Guernsey rates stood at 30s., plus 1d. per call. Municipalities must not disdain to touch whatever is found convenient to customers, whether party or omnibus lines.—ED. *E. E.*]

* The people's part is to make quite sure in advance that no foolish contract is entered into. What is wanted are cheap rates, such as are charged by the British corporations who own telephone systems, by the National Telephone Company itself wherever it is face to face with competition, by the Continental telephone administrations, and by the independent telephone companies in the United States. All these show that a rate of between £5 and £6 per annum for an exclusive direct line to the exchange with unlimited calls is remunerative, and that is what must be insisted on in this country. If the Post Office cannot pledge itself to that in advance, then it has no right to buy the telephones. It is no use fixing a price and then discovering too late that, in order to earn interest on it, a rate of £8 to £10 a year must be charged. The business way is to calculate beforehand the maximum sum that is admissible on the basis of, say, a £5. 10s. rate, and if the company will not take it, drop the matter once and for all until the flux of time gives again the right to buy compulsorily by arbitration.

## *RE* QUESTION 755.

SIR,—In the current issue of the *Electrical Engineer*, in the "Questions and Answers" column, the second answer to Question No. 755 contains a slip which has led its writer, "W. T. W.," to an erroneous conclusion. In the course of his explanation, "W. T. W." says, after mentioning that the exhaust steam is taken into the chimney near the base, "this gives us 35ft. per second as the velocity of the steam, and consequently (of?) the hot gases within the chimney." The latter part of the sentence is, of course, incorrect, seeing that before the introduction of the steam the flue gases had a velocity of 16·8ft. per second only. To get an idea of the velocity of the mixed gases we can use the principle of momentum, by which

$$m_1 v_1 + m_2 v_2 = M V,$$

$m_1$ $m_2$ being the respective masses of steam and flue gas, and $v_1$ $v_2$ their respective velocities before impact M is the sum of the masses, and V the velocity after impact. Take the case of a plant exhausting 21lb. of steam per indicated horse-power hour, using 4lb. of fuel with 20lb. of air per pound of fuel. Then the relative masses of steam and flue gas at the base of the chimney will be 21 to $4 + (20 \times 4) = 1$ to 4, or $m_1 = 1$, $m_2 = 4$; and, further, we have $v_1 = 35$, $v_2 = 16{\cdot}8$. Substituting in the above equation $1 \times 35 + 4 \times 16\,8 = 5$ V—*i.e.*, V = 20·4ft. per second. Substituting this value in the equation $V = \frac{8\sqrt{H}(600-62)}{3\,3 \times 600}$ we find H = 88ft., thus gaining 28ft. on a 60ft. stack. In practice the gain is not so great as this, for the following reasons:

1. The value of V is not as great as obtained above, on account of internal losses in the mixture of the gases.

2. After the steam has travelled a few feet above the point of entry, where it has a temperature of about 212deg. F., it abstracts a considerable proportion of the heat in the flue gases, reducing the temperature of the latter, and this reduces the draught.

3. The steam expands with this rise of temperature, and occupies a portion of the volume of the chimney, further reducing the draught by a throttling effect.

These considerations show, what has been found in practice, that turning exhaust steam into a high chimney has very little effect on the draught.—Yours, etc.,

B. W. X.

## FOREIGN LAMPS.

SIR,—With reference to the "flame" arc lamps put up in the vicinity of the Mansion House, and respecting which a notice recently appeared in the technical papers, it has no doubt escaped the notice of the City lighting authorities that the arc lamps which have been fitted up are of German manufacture. In view of the present state of trade it seems rather peculiar that the premier city of the Empire should have to go abroad for arc lamps to light its streets, when there are in this country numbers of manufacturers of *high-class arc lamps*, both "flame" and otherwise, who would be only too pleased to submit most satisfactory lamps for practical tests on the streets, more particularly because in this case, if the trials prove satisfactory, a very large number of lamps will be required.—Yours, etc,

OBSERVER.

## 160-H.P. MOTORS.

SIR,—Though probably too late, I should like to submit an explanation to your Question No. 756, *re* the 160-h.p. 400-volt motor, several answers to which are printed in your last issue. I have had two similar occurrences recently with 450-volt motors. In the first case the brushes had been reversed, but the rocker had not been properly set afterwards. In the second case the brushes had been fitted to face the wrong way round, the spindles in this case being fixed. In both these cases one brush invariably kept most of the sparking and all the flashing over to itself. Now, I take it that the machine in question was installed in its permanent position, and not running on test at the maker's. In this case it is quite conceivable that the machine had been taken apart for packing, and afterwards

Digitized by Google

erected by men "on the job." In many machines it would be perfectly easy for the brushes under these conditions to be put on wrong way round. However, when the machine is at rest it is a very simple matter to check this: examine the armature and see which coil is midway between two pole-tips, follow this coil along to its connection on to the commutator, and the bar to which this is connected will be the approximate position for the brush.

I do not think there could be much wrong with either the armature or the field. In the first case the preliminary shop tests (galvo and insulation) pretty well ensure the armature being sound, while the resistance and insulation tests to the field coils should prove these good. I cannot understand that in the event of a field coil being wrongly connected the circuit breaker waits until the third contact is reached before opening. In this last case the ammeter readings would have helped us, but unfortunately these are not given.—Yours, etc., H. M. M.

## THE SINCLAIR VARIABLE-STROKE FEED PUMP.

SIR,—We were pleased to see that you gave such an interesting notice of our variable-stroke boiler feed pumps in your last issue, but there is one small matter to which we should like to draw your attention.

You mention that the curve of test shown refers to 2,000-gallon pump. We should like to point out that although this test was taken from a machine capable of pumping up to the capacity of 2,000 gallons, the actual test was taken at a slower speed, giving a maximum discharge of 1,000 gallons per hour, so that the total efficiency does not show out as well as it would if the machines were fully loaded and working to the maximum capacity.—Yours, etc., HAYWARD-TYLER AND CO.

## GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The monthly meeting of this section was held on Tuesday evening, when the discussion on Mr. Maxwell's paper on street arc lighting was continued.

Mr. W. W. LACKIE (member) read a paper on "Earthing." "An earth," he said, "had been legally defined as follows: 'The earth is an earth, but an earth need not necessarily be the earth.'" After quoting the rules referring to earthing in the rules and regulations recommended for wiring for the supply of electrical energy issued by the Institution of Electrical Engineers and the rules in Glasgow Corporation general rules, he went on to state that during the years 1902, 1903, and 1904 35 fires were reported to the electricity department of the Glasgow Corporation by the fire department as having been due to defective electric light installations. Two of these were, in the opinion of the electricity department, not due to electricity at all. Of the remaining 33, 15 were due to the melting of gas-pipes by a current of electricity, the installation in each case having been carried out with metal-sheathed cables; eight of the fires occurred on installations where the metal piping or metallic sheathing of the cables were not properly earthed; seven were on installations where the iron piping or metal sheathing was earthed. The causes of the remainder have probably no bearing on the subject of earthing, but may be of sufficient interest to be stated here: five were caused by the cables having been chafed, and the insulation consequently damaged by contact with the sharp edges of iron pipe ends; one was due to a piece of hot carbon falling from an arc lamp upon some muslin goods in a shop window; five were due to defective twin flexible conductors; three were due to deterioration and defects in switches; three were due to wooden casing having been saturated with water; and one was caused on a wood casing installation where the conductors were not protected, but were lying against a soft gas-pipe, and the insulation of the conductor failed. Perhaps it might be well to point out in passing that the effect of these fires was much more serious in the 15 cases where soft gas-pipes were melted, and the author begs to express the hope that electrical engineers will do all they can to stop the use of this class of pipe, and, if possible, see that it is removed from any building into which electric lighting or power is being installed. Considering, however, only the first 15 cases, and especially the seven where the metal sheathing was earthed, the fact of current going *viâ* the gas-pipes at all goes to show one of two things—viz., either that the current flowing to earth and back to the generating station divides up between the one, two, or more paths to earth in proportion to the conductivity of these different paths, or that by increasing the earth connections the current going to earth is increased by the increased conductivity to earth of the earth circuits. It is, further, impossible to test an installation after it is completed, with a view to ascertaining whether the metal sheathing is in itself properly electrically continuous throughout its entire length, and whether the continuity of earthing throughout is not due to the sheathing being earthed at one point by the earth-wire run for that purpose, and at another point by means of a gas-pipe or other pipe. It may be that for part of the course a gas or water pipe is the bonding or cross-connecting link between two lengths of sheathing.

With the present system of earthing, if one conductor came in contact with the sheathing, the current that flows momentarily, but long enough to blow branch and main fuses, was frequently 250 to 300 amperes, and was sufficient to interfere with the supply to other consumers. It had often been found that a momentary short-circuit was due to an earth on a three-ampere branch circuit in a consumer's premises. Bearing these facts in mind, the author has come to the conclusion that the present method of earthing at any point and direct is wrong, and it is his opinion (1) that the metal sheathing on installations for connection to public supply mains should be kept clear of all other metal work throughout the entire run of the conductors; (2) that the connection to earth should be through a resistance of such an amount as would allow not more than, say, two or three times the normal current of the installation flowing to earth in the event of one of the conductors coming in contact with the sheathing; and (3) that the metal sheathing on installations for connection to public supply mains should be joined to earth at one point only.

The author then went on to speak on each of these three points. With regard to (1) metal sheathing kept clear of all other cables, he said that in the Glasgow provisional order it was distinctly stated that the Corporation were not, except with consent, to lay their electric lines in contact with any such mains. It followed, therefore, that if it was necessary to keep clear of other pipe work under ground, it was obviously just as necessary to keep clear of pipes and metal work inside buildings. If the sheathing used for electric lighting and power conductors was insulated throughout its entire length, it would be possible to test, after any installation was completed, and to see that the cable sheathing was clear of all other metal work in the building, and also that it was in itself electrically continuous. With regard to (2) a resistance in the earth circuit, if there was such a resistance the rush of current would be reduced so enormously as to make the main fuse strong enough to resist it. It would be even a better arrangement if each set of branch pipes had a proportionate resistance inserted to a separate slightly insulated earth wire and the sheathing of the mains had also a resistance. In using metallic-sheathed conductors it had formerly been common practice to have the main fuses enclosed in cast-iron boxes, these boxes being earthed through connection to the metallic sheathing. It had then been frequently found that when a fuse blew, an arc was formed between a conductor and the case, owing to the distance between the 'bus bar and the side of the case being less than the break of the fuse, and strong enough to keep up an arc. Sometimes this arc had melted a hole in the iron box as well as below the main fuse. As a remedy some engineers insulated these boxes by mounting them on wooden bases and connecting the pipes across the gap by means of a bonding wire, or having the fuses enclosed in a wooden case. A similar course had been adopted where an arc had formed between one of the terminals or blades and the side of the switch box. One good reason for earthing the metallic sheathing covering electric conductors is, of course, the prevention of

Digitized by Google

possible dangerous shock to the public, and the insertion of a resistance of the size suggested would not militate against this in any way. Several stations have adopted this course to protect their works from a complete shut-down. To ensure continuity of supply the middle wire of the three-wire system is earthed through a resistance of a tenth of an ohm, or in some cases one ohm.

Mr. A. P. Trotter had constructed a mechanical model to show the difference of pressure between each of the three conductors on a three-wire system, and each with varying leakages or earths. This device was described at length, but as it has been already described in Mr. Raphael's book on "Faults in Electric Mains," Mr. Lackie's description of it is here omitted. The idea of introducing a resistance to the extent suggested on the earth circuit is probably novel, so far as wiring is concerned, but to introduce a resistance of some kind is not new in underground mains work, as the Howard Conduit Company, Trafford Park, Manchester, in a descriptive pamphlet of their asphalt conduits for underground mains, advocate this. If in circuit with or if the earthing resistance on a consumer's premises took the form of an electromagnet, which would close a secondary circuit so as to ring a bell, sound an alarm of some kind, or light a tell-tale lamp, each installation would become self-testing. The winding of the resistance in the form of an electromagnet would also, in cases of dead earths, act momentarily as a choking coil. We are all agreed that a fuse of a certain capacity affords no protection against leakage current, which is, as a rule, leakage to or from earth, so long as that current does not exceed that at which the fuse will blow. The above arrangement would act before the fuse, and even a simple electromagnet in circuit with the earth-wire without the resistance advocated would always be an advance on present practice. It has frequently happened that for some reason or other the fuse on the branch main connected to the neutral wire on a two-wire installation has gone, and the installation has had an earth connection on the same conductor inside the premises beyond the fuse. The installation still continues to have a satisfactory supply through this earth connection and the earth connection at the generating station. If a resistance of the amount suggested was inserted in the earth connection, the chances are that the consumer would very soon see that something was amiss, due to the bad pressure brought about by the supply having to come or go by the earth resistance; and, moreover, if a bell or other device was connected, as indicated, with the resistance, it would immediately show that current was passing by the earth circuit. If earthed at more than one point, several resistances would be required, so that the joint parallel resistance should equal a resistance such that only two, or say, three times the normal current would flow to earth; but further current is diverted over the other metal work of the building if earthed at several points. If several paths are given between the metal sheathing and earth on different floors of a building, there is, as before, current diverted over all the other metal work of the building, and such stray current may cause arcing sufficient to melt pipes—gas and water—and, if gas, fire will result. The resistance of 50 yards of $\frac{5}{8}$in. tubing with joints was ·4 ohm, and the resistance of 50 yards of lead covering of $\frac{3}{20}$ twin lead-covered wire, ·8 ohm. It looked from that, therefore, as if the current to earth would equal a considerable pressure divided by the resistance to earth of each circuit, and that might explain the melting of the gas-pipes and consequent fires in the seven cases of fire referred to.

Faults had occurred on lead-covered conductors due to a broken strand getting in contact with the lead covering. The momentary flow of current in such a case had often been so great as to burn the lead clean off at the point of the broken strand, and the fuse on the circuit had sometimes gone and sometimes stood. Where it had gone it would be replaced, and the installation might seem all right, but trouble would be experienced sooner or later with a conductor in such a state. Might the same reasoning not be used in advocating the introduction of a resistance on the earthing wire from a motor or dynamo? The comparatively enormous damage generally done to a small motor when one of the conductors in it went to earth, in the opinion of the author, justified putting in a resistance to limit the current. By insulating the sheathing throughout its run, earthing it at one point only, and introducing proper sized resistance on the earth circuit, they had (1) made it possible to make a further and important test at all times, even after an installation has been completed; (2) increased the efficiency of the supply; (3) reduced the already small risk of fire from electrical causes; (4) in no way interfered with the precautions for the safety of the public from shock; (5) rendered installations continuously self-testing. The reason for insisting that fittings and lampholders should be insulated was that if the lampholders were not insulated they would most assuredly break down the insulation of the lamp caps in use. Cases were on record where the insulation between the lamp-collar and one of the terminals was nil. All lamp caps on 250-volt lamps would stand 250 volts between the two terminals, but few would stand 250 volts between one of the contacts and the metal collar on metal-collared lamps, or the lampholder on porcelain or vitrite-capped lamps. Besides, it would have been noticed that in the abnormal state of division of pressure between the positive, neutral, and negative conductors and earth—*i.e.*, when the positive or negative main was to earth—it was quite possible that between one lamp contact and earth, if the holders were earthed, there would be at times a difference of pressure of 500 volts. The lamps in general use to-day were not meant for this, and consequently the simplest and the cheapest way was to insulate the lampholders and remove these two dangers.

## AUSTRALIAN TRAMWAY SYSTEMS.

In no part of the world, in proportion to the number of population, are street tramways more extensively used as a means of passenger transit than in the leading Australian State capitals. Although their introduction is of comparatively recent date, their development has been marvellous, and, as in many European and American cities, they have assisted in making riding cheaper than walking, and are causing the omnibuses and other conveyances of a past generation to become forgotten. In Sydney the tramways were originally worked by steam power, the cars being double-decked, like the railway carriages on several of the Paris suburban lines, but subsequently the cable system was introduced, and later on electricity became utilised as the motive power, and with such success that it is only a question of time when the locomotive and cable will be found dispensed with. The various tramlines, which, like the railways, are the property of the State, form a complete network of communication between nearly every part of Sydney and its suburbs, thus assisting in counteracting the tendency to overcrowding, which forms one of the evils associated with large centres of population. The total length of tramlines open on June 30, 1903, was 124½ miles, representing an expenditure of £3,371,587 for construction and equipment, the number of passengers carried during 1903 being 130,405,402. The Melbourne system, embracing a length of 48 miles, 43½ miles of which are worked by cable and 4½ miles by horse power, was constructed by a municipal trust at a cost of £1,705,794, and is leased to a company. It is said to be the largest and best cable system in existence. The number of passengers carried during the year was 47,564,942. There are also several suburban lines worked by limited liability companies, as follows: horse, 8½ miles; electricity, 4 miles; and cable, 2¼ miles. In Brisbane the tramlines were originally worked by horse power, but in 1897 it became replaced by electricity, the tramways being the property of an English company, and covering a total length of 28 miles. As the traffic increases, extensions are effected. At the close of 1902 there were in the State 65 miles of tramways, including those in Brisbane, the number of passengers carried during 1903 being 18,125,302. In Adelaide there are several tramway lines worked by horse power, but an attempt is being made to secure the introduction of the electric system. The lines are owned by private companies, In Western Australia, Perth has a well-organised system of electric tramways, which, like that in the Kalgoorlie municipalities, is the property of a private company.

Digitized by Google

Fremantle and Boulder City also will shortly be in possession of electric tramway systems, constructed by private enterprise under municipal supervision. The only State-owned tramway is that running between the port of Roebourne and the town of Cossack, a distance of 8½ miles, in the north-western portion of the State. In Tasmania the Hobart tramways are worked by electricity, and extend a distance of about nine miles. They are owned by a private company, and were opened in 1901, in which year they carried 1,432,176 passengers. There is also a steam tramway in the north-west portion of the State, connecting Zeehan with Williamsford, a distance of 11 miles, its summit being 1,500ft. above sea-level. Compared with other Australian tramway systems, that of Sydney is considerably the most efficient, there being a continuous succession of trams from early morning until midnight, an all-night service being established on several lines. During the earlier hours of the day and in the evening the tram traffic is enormous, the cars, running almost every minute, being densely crowded. It is the same at holiday time, and the greater the amount of accommodation provided by the State Railway Commissioners the denser becomes the crowding. It is as if the whole population desired the use of the tramcars. Yet, with all this heavy traffic, accidents are comparatively few, being in most instances due to the disregard of ordinary precautions on the part of the sufferers. All the Australian electric systems are on the overhead wire principle, which is not found to interfere with the work of fire brigades to anything like the extent originally anticipated. The cost of the New South Wales tramways was defrayed out of loan revenue, and they constitute one of the most valuable assets of the State.

## CATALOGUES, ETC., RECEIVED.

PUMPS.—Messrs. Balcke and Co., condenser specialists, 27, Clement's-lane, London, E.C., have sent us a pamphlet describing some of their electrically-driven and other pumps.

MECHANICAL STOKERS.—A pamphlet, entitled "Cheap Steam," issued by Messrs. Ed. Bennis and Co., Limited, Bolton, describes and illustrates their stoker and compressed-air furnace.

ARC LAMPS AND METERS.—Mr. G. Braulik, 217 and 218, Upper Thames-street, London, has issued a new catalogue and price-list of his London-made arc lamps; also a new list of "Eclipse" electricity meters.

CABLEWAYS, ETC.—Messrs. Graham, Morton, and Co., Limited, Hunslet (Pepper-road), Leeds, have sent us a catalogue describing their cableways, cantilever cranes, electric telpherage, aerial ropeways, etc.

BAILEY'S VALVES.—We have received from Messrs. W. H. Bailey and Co., Limited, Albion Works, Salford, Manchester, a copy of Part 9 of their catalogue, Section 1. This part deals with valves of the firm's latest improved types for power stations and works.

FULL-SIZE SECTIONS.—From Messrs. Hardy and Padmore, Limited, Worcester Foundry, Worcester, we have received three sheets illustrating full-size sections of manholes and inspection pit covers, with particulars attached. The sections represent stock patterns, and should be especially useful to consulting engineers.

WESTERN ELECTRIC SPECIALITIES.—The Western Electric Company, North Woolwich, London, have sent us copies of their latest price-lists, enclosed in a binder. These lists deal respectively with continuous-current fan motors, enclosed arc lamps, continuous-current circuit breakers, sewing-machine motors, and motor-driven grinders.

SWITCHBOARDS.—A pamphlet just issued by Messrs. Johnson and Phillips, Old Charlton, Kent, contains illustrations of a number of switchboards designed and constructed by the firm. The selection has been made, we are told, with a view to showing the variety and scope of their work in this department, and what the different types of board look like when erected.

ELECTRICAL HEATING.—We have received from the Electric Heating Company, 3, Holborn-place, London, W.C., a copy of their list of patent Phœnix heaters and cookers. The great progress recently made in the design and manufacture of this class of apparatus is well illustrated by this list, which includes a great variety of useful types, all, we are told, made in England.

THE METAPHONE.—From the National Telephone Company, Limited, Victoria-embankment, London, E.C., we have a copy of their revised and enlarged catalogue of metaphones. The metaphone, it may be repeated here, is a complete telephone transmitter and receiver for use in connection with existing electric bell wires, bells, etc., and batteries in houses, offices, hotels, etc. Several patterns are illustrated.

AIR-COMPRESSING PLANT.—Air-compressors are dealt with in a new catalogue recently issued by Mr. Peter Brotherhood, Belvedere-road, Westminster Bridge, S.E. These compressors, we are told, have been specially designed to meet in the best manner possible the rapidly growing requirements of users of pneumatic tools and other machinery and appliances worked by compressed air. The illustrations of standard Brotherhood air compressors are excellent, and full particulars are included.

COLLIERY CABLES.—From the St. Helens Cable Company, Limited, Warrington, we have received a copy of their new catalogue of dialite cables for use in collieries. The special features of dialite cables are dealt with at some length, and the reports of independent tests given, while several methods of fixing or laying cables in mines are illustrated. These methods are founded on the many years of experience which the company have had with this particular class of work, and make a useful addition to the catalogue.

PAPER-INSULATED CABLES.—From Messrs. W. T. Henley's Telegraph Works Company, Limited, Bloomfield-street, London-wall, E.C., we have received a copy of their very conveniently arranged new price list of paper-insulated cables for electric lighting, power, and traction, comprising low-tension, single-concentric, triple-concentric, twin, three-core, and high-tension concentric cables. We note that the specification of cables, details of conductors, etc., contained in this list are in accordance with the recently issued report of the Engineering Standards Committee.

## FORTHCOMING EVENTS.

FRIDAY, FEB. 17.

**Royal Institution.**—At 9 p.m., "High-Power Microscopy," by Mr. J. W. Gordon.

**Institution of Mechanical Engineers.**—At 8 p.m., discussion on adjourned papers. Prof. W. E. Lilly will read a paper on "The Strength of Columns."

**North-East Coast Institution of Engineers and Shipbuilders.**—General meeting at Newcastle.

**Electrical Engineers (R.E.V.)**—At 8 p.m., Bohemian concert at the "Horns," Kennington.

SATURDAY, FEB. 18.

**Glasgow Technical College Scientific Society.**—At 7.30 p.m., "High-Speed Tool Steels from the User's Point of View," by Mr. E. H. Robertson.

MONDAY, FEB. 20.

**Society of Arts.**—At 8 p.m., "Internal-Combustion Engines" (Lecture II.), by Mr. Dugald Clerk.

TUESDAY, FEB. 21.

**Institution of Electrical Engineers (Manchester Section).**—At 7.30 p.m., "Manchester Tramways Power Supply," by Messrs. H. C. Gunton and S. L. Pearce.

**Institution of Civil Engineers.**—At 8 p.m., resumed discussion on "Alfreton Second Tunnel" and "The Reconstruction of Moncreiffe Tunnel." Paper, "Surface-Condensing Plants, and the Valve of the Vacuum produced," by Mr. R. W. Allen.

**Institution of Engineers and Shipbuilders in Scotland.**—At 8 p.m., general meeting.

THURSDAY, FEB. 23.

**Institution of Electrical Engineers.**—At 8 p.m., "The Value of Overhead Mains for Electric Distribution in the United Kingdom," by Mr. G. L. Addenbrooke (continuation of discussion).

**Tramways and Light Railways Association.**—At 8 p.m., "Brakes," by Mr. G. A. Trube.

FRIDAY, FEB. 24.

**Physical Society.**—At 5 p.m., "The Curvature Method of Teaching Geometrical Optics," by Dr. C. V. Drysdale; exhibition of Dr. Meisling's colour-patch apparatus, by Mr. R. J. Sowter; and "A Method of Illustrating the Laws of the Simple Pendulum," with an exhibition of string models of optical systems, by Mr. J. Schofield.

**Institution of Electrical Engineers (Manchester Students' Section).**—At 7.30 p.m., "Metallography," by Mr. Buttenshaw.

**Electro-Harmonic Society.**—At 8 p.m., ladies' night.

**Institution of Civil Engineers (Students' Section).**—At 8 p.m., "Morecambe Sewerage: Method of Laying a 15in. Cast-Iron Sewer under the London and North-Western Railway," by Mr. F. D. Flint; and "The Reconstruction of Bow Bridge over the River Lea," by Mr. H. M. Rootham.

## ELECTRICITY SUPPLY PUBLICITY DEPARTMENTS: A SUGGESTION.

BY B. C. H. J.

As mentioned in this paper of the 3rd inst., the Croydon electricity scheme now possesses a publicity department. This is not quite a novelty, of course, as several of the power companies depend largely upon a similar department for their customers, and in due course all large undertakings will most probably follow suit.

It is in regard to the smaller supply stations, however, that this article is written: those concerns which obviously could not afford to maintain such a department, but at the same time feel the need of it quite as acutely as the larger works. In such towns, in addition to the efforts of local contractors, the resident engineer generally combines to a slight extent the duties of publishing the advantages of electric supply with his own often more pressing work. The chairman of the electricity committee will also often help in the work of conversion by persuasion or personal influence; but he, too, is usually a man with plenty to do and very little time to do it in. In the case of local companies, the secretary takes the committee chairman's place in well-meant but untechnical efforts. In very few instances are the other members of the electricity works staff taken into consideration in the matter. The principal reason is that the local wiring contractors are supposed to do this class of touting to the extent necessary, and in some cases they manage it effectively enough. This is when they have had sufficient experience or technical training to be able to give a possible client the information required, which occasionally is somewhat special and outside the mere room-lighting routine. In a great many instances, however, more mechanical and "moving machinery" knowledge is required in order to answer questions, and here is where the assistant engineers would shine if given the chance.

The scheme that the writer proposes is for the manager of the electricity works to encourage assistant engineers to obtain customers by the payment of a fixed fee per installation secured by them. This would not only help the load curve of the station but the banking account of the assistant, which matter is now become of dwindling dimension, but increasing moment to those concerned. Where several assistants are employed in this way, a bonus might be granted to the one whose consumers had the greatest equivalent numbers of lamps wired, or whose consumer's first quarterly accounts were the largest. The opportunity for this work would be easily found at convenient times during the 16 hours per day off duty, and as such engineers would have opportunities for recommending wiring contractors, there would possibly be another source of income from that part of the scheme to encourage him to do his best. It would have to be understood, however, that the assistant who recommended a contractor was to a certain extent responsible for that contractor's work, to prevent the possible sacrifice of good material and workmanship on account of the bonus. As regards this bonus, it might possibly be a cause of trouble if improperly worked, but there should be no harm done in trying it, and the fact remains that (with most men) the more the metallic incentive the more the exertion.

## OLYMPIA MOTOR EXHIBITION.

The third international motor exhibition, now being held at Olympia under the auspices of the Society of Motor Manufacturers and Traders, Limited, is by far the largest and most important of its kind ever held in this country. It is even doubted by many whether the recent Paris show was its superior. Not having seen the latter, we can't say. So far as we are concerned, the excellence of the arrangements made by the society, the advantages of the new and altered Olympia, its suitable situation for the purpose, and its magnificent new electric lighting installation, are quite in unison with the great progress shown by English exhibitors of motor vehicles for use on land and on water. This progress is mostly visible in the construction of the carriage part proper, the upholstering, improved seating accommodation, and increased leg-room. Petrol seems to rule the day, although there are a few very fine specimens of electric carriages amongst the exhibits. On the whole, there appears to be reduction of prices and a tendency to do with as few cylinders as possible, one and two for the lighter and three and four for the heavier cars. The commercial omnibus and railway motor section is well represented, and British builders more than shine in the boat exhibits. The exhibition will remain open until Feb. 18 inclusive. T.R.H. the Prince and Princess of Wales visited the exhibition both on Friday and Saturday. On the opening day the exhibitors and friends attended a very successful luncheon, at which Mr. Sidney Straker, A.M.I.C.E., presided, the Right Hon. Lord Stanley, C.B., M.P., being the principal speaker. These proceedings have already been very fully reported in the daily Press.

We were specially interested in the electric ambulance van exhibited by the Electromobile Company, Limited, 7, Curzon-street, W. With regard to its equipment, it is complete, and of the latest pattern. It is fitted with two full-length stretchers, which slide into the van from behind, one above the other. A wide passage for the attendant runs down the right-hand side of the van. The carriage is lighted and warmed by electricity, and is completely fitted with all necessary appliances for first aid. The driver's seat is covered, as a protection from weather, and telephone communication is provided between the driver and the attendant. The van is intended entirely for city use. A distance of 25 miles can be covered on a single charge of the battery, and an exhausted battery can be exchanged for a fully charged one in two minutes. It is mounted on the company's latest type of chassis. Several important improvements have been introduced. The front wheels have been set forward 6in., giving a slightly longer wheel base, and the rigid front spring hangers have been replaced by half-springs. The rear suspension has also been improved by the addition of a transverse spring, which supports the weight of the body, and to which the side springs are attached in the usual manner. A new form of magnetic cut-out or current breaker has been introduced, replacing the ordinary form of sliding contact. In practice this has been found to be very efficacious, eliminating all trouble from burnt contacts. The chassis is fitted with a safety device, which prevents the chauffeur from inserting the running plug in its socket except when the controller is on the zero or neutral position. The socket has been removed to a conspicuous position in the front of the car, so that a casual glance will show whether the plug is in position or not. All carriages of the company are now fitted with an efficient mileage recorder. The counter, which can be locked, is fitted to the chassis in a conspicuous position at the rear. It is driven by means of bevel gear and flexible shaft direct from the gearing. The company further show two elegant electromobiles, one with brougham and one with landaulet body.

S. F. Edge, Limited, 14, New Burlington-street, W., show a 30-h.p. chassis, fitted with a six-cylinder Napier engine, electrical Napier patent synchronised ignition, and hydraulic air regulator to the carburettor. The ignition apparatus contains a low-tension commutator and high-tension distributor, both of which are driven simultaneously from the engine by a vertical shaft passing through spiral gear wheels, which mesh with the wheel. It is directly connected with the lubricator, the latter being driven by a chain which passes round a sprocket. A single-trembler coil forms a part of this compact apparatus, with "timing" lever arranged close up to it.

Messrs. W. and F. Thorn, 19, Great Portland-street, Oxford-circus, W., and Ranelagh House, Lower Grosvenor-place, S.W., London, exhibit the "Silvertown" motor and chassis and an electric landaulette of very light construction, to seat three or four inside and two out; suitable for 12-h.p. motor. The chief feature of these carriages is the "Silvertown" patent drive, which, operating on all four wheels, gives a more even tractive effort on the road. It is claimed that the "Silvertown" system of control is practically "fool-proof." A slight movement of the brake pedal breaks the circuit, connection being made again when the pedal is released, provided the pedal is not depressed enough to put on the brake. This arrangement proves very useful in traffic work, and as a safety device when turning corners, etc. Directly, however, the brake pedal is fully depressed, a braking effect takes place and the current is permanently shut off until the controller is brought back to the neutral position, when it is automatically made again. By this arrangement it is impossible for the car to start forward again when the brake pedal is released, after having been brought to rest by the brakes, although the controller handle may have been left in a forward position. The controller handle is placed underneath the steering wheel in front of the driver, and not at the side as is usually the case, and is therefore easily operated in case of any emergency. The battery consists of 44 cells in ebonite trays, contained in teak wood boxes, sufficient for a distance run of 35 miles on one charge on good level roads.

The Kriéger Electrical Syndicate, 38A, Gillingham-street, S.W., have an electric carriage on their already described system, and this practically completes the electrical car section.

Messrs. Clement-Talbot, Limited, Edinburgh-road, Ladbroke-grove, North Kensington, W., amongst their standard 1905-

Digitized by Google

models have a "C.T.2.O." two-cylinder 10 h.p. to 12 h.p., with ignition by high-tension magneto. Honeycomb radiator. All organs of the motor, such as carburettor, pump, etc., are carried on the motor itself.

Amongst the commercial exhibits we noted specially a 2½-ton and a five-ton steam motor-wagon, both very serviceable and fitted with attachment for taking a trailer, exhibited by Messrs. E.S. Hindley and Sons, Bourton, Dorset; and two fine three and five-ton tip wagons, shown by the Bristol Wagon and Carriage Works Company, Limited. The Straker Steam Vehicle Company, Limited, 9, Bush-lane, Cannon-street, E.C., make a good show with their specialties in tipping and other wagons. Messrs. Johnson and Phillips, London and Charlton, show a 16-h.p. chassis fitted with the "Newman" variable speed gear, type "R.A. No. 4," and Newman's adjustable universal couplings, showing system of control, emergency clutch, chain drive, etc., in motion, and various types of the "Newman" variable speed gear. Messrs. Peto and Radford, Limited, 55 and 57B, Hatton-garden, E.C., 61, Chandos-street, Strand, W.C., and Greville Works, Ashstead, Surrey, have a very large and varied assortment of electrical apparatus for use in electric ignition and electric lighting on motorcars, comprising accumulators, induction coils, contact breakers, measuring instruments, magnetos, dynamos, and electrical accessories.

In the same section we noticed lubricating and other oils by the Anglo-American Oil Company, Limited, 22, Billiter-street, London, E.C., and the Vacuum Oil Company, Limited, Norfolk-street, London, W.C., and patented oil cans, etc., by Joseph Kaye and Sons, Limited, 93, High Holborn, W.C., and Patent Lock Works, Leeds.

Messrs. Ransomes, Sims, and Jefferies, Limited, Ipswich, show 24-h.p. to 42-h.p. motor lawn mowers of neat construction, the mechanism of which is easily accessible to the attendant walking behind. Messrs. Willans and Robinson, Limited, Victoria Works, Rugby, and Queensferry, have a large exhibit of tube steel, forging steel, and high-tensile vanadium steel castings and motorcar cylinders. Messrs. David Moseley and Sons, Limited, Chapelfield Works, Ardwick, Manchester, show the "Seddon" tyre in red rubber, which is novel in design and simple of attachment, requiring no inner tube or security bolts.

We are asked to draw attention to the Motorcar Company's new system for protection of purchasers, by means of which intending purchasers may have their car selected by a jury composed of W. Worby Beaumont, Esq., M.I.C.E., M.I.Mech.E.; Dugald Clerk, Esq., M.I.E.E., F.C.S.; Colonel Crompton, C.B., R.E.; Robert E. Phillips, Esq., M.I.Mech.E., A.M.I.C.E., A.I.E.E.; and Alfred J. Boult, Esq., M.I.Mech.E. (Messrs. Boult, Wade, and Kilburn, chartered patent agents).

## INSTITUTION OF ELECTRICAL ENGINEERS.

At the ordinary general meeting on Feb. 9 the following candidates were elected:

*Members.*—A. F. Ball, 14, Lansdowne-terrace, Gosforth, Newcastle-on-Tyne; T. Tomlinson, Northumberland House, Beresford-place, Dublin; A. Wyllie, Wolverhampton-street, Walsall.

*Associate Members.*—W. M. H. Butcher, 22, Maple-road, Anerley, S.E; T. A. Cunliffe, 27, Howard's-lane, Putney, S.W.; F. W. Davies, 47, Cleveland-road, Huddersfield; P. J. Hood, C. S. "Electra," Eastern Telegraph Company, Limited, Suez; S. T. Land, Electricity Works, Rathmines, co. Dublin; R. W. McOlay, Messrs. Balmer, Lawrie, and Co., 103, Clive-street, Calcutta, India; A. J. Makower, 37, Maresfield-gardens, N.W.; J. Place, 46, Watling-street, London, E.C.; T. Schontheil, 14, High-street, Cardiff; R. J. Shaw, 36, Lincoln-street, Gateshead-on-Tyne; R. J. Smith, 76, Tollington-road, Holloway, N.; G. B. Williams, 5, Kensington-masions, Earl's Court, S.W.; F. W. Wyand, Elswick Works, Newcastle-on-Tyne.

*Students.*—C. S. Atkinson, Beta Lodge, Padgate, near Warrington; T. M. Barlow, The University, Birmingham; H. F. Barnes, Comer Villa, Bromyard-road, Worcester; R. G. Barrett, 54, Florence-road, Stroud Green, N.; W. F. Birch, 9, Alma-terrace, Kensington, W.; J. B. Blake, Faraday House, Charing Cross-road, W.C.; W. P. Brennan, 164, Coningham-road, Shepherd's Bush, W.; E. J. D. Buckney, 37, Finsbury Park-road, N.; W. C. C. Chappell, 17, Hornsey Rise-gardens, N.; D. P. Dunn, 19, Grafton-road, Bedford; O. Faber, Fiona, Leonard-road, Penge; K. B. Findlay, Faraday House, W.C.; B. S. Fowler, 25, Clarendon-buildings, Balderton-street, W.; C. Harrison, Faraday House, W.C.; W. Lawrence, 28, Steven-street, Stretford, Manchester; C. R. McGowan, Maghera, co. Derry, Ireland; J. H. McMinn, 50, Gibson-street, Hillhead, Glasgow; J. A. Marshall, Westbrook, Glendale-road, Eccles; W. H. S. Mitchell, 25, Alexander-street, Bayswater, W.; V. Muirhead, Faraday House, W.C.; C. T. Pressland, The Croft, Grimwood-road, Twickenham; T. A. Pudan, Faraday House, W.C.; C. P. Richards, 79, Ryland-road, Edgbaston, Birmingham; T. A. Rose, The Schools, Feltham, Middlesex; W. H. Russell, 53, Netherhall-gardens, Hampstead, N.W.; G. Tingley, 61, York-street, Walworth-road, S.E.; F. L. N. Tuck, 37, St. Oswald's-road, Fulham, S.W.; C. Vandermin, Faraday House, W.C.; M. Vela, 4, Sandoft-road, Eastcombe-avenue, Charlton; I. D. Whittall, Stamford Lodge, Bowdon; G. H. Wilson, Eggleseliffe, co. Durham; W. D. Wivell, Keswick Hotel, Keswick.

## JUNIOR INSTITUTION OF ENGINEERS.

A dinner to celebrate the coming of age of the Junior Institution of Engineers was held at the Hotel Cecil on Saturday last, under the presidency of Mr. W. H. Lindley, M.I.C.E., F.G.S. After the loyal toasts had been duly honoured, Prof. W. E. Ayrton, F.R.S., proposed "Legislation and Engineering," referring incidentally to Mr. Lindley's connection with the Frankfort Exhibition of 1891, and the electrical transmission scheme which attracted such universal attention at the time. Mr. James Swinburne, M.I.C.E., and Mr. J. H. Balfour Browne, K.C., responded. Robbed of its witticisms, the latter's speech was to the effect that science and experience led legislation. The President then proposed "The City and Port of London." In the absence of Mr. W. H. Grenfell, M.P., Archdeacon Sinclair responded. While acknowledging the benefit derived from the many great engineering works carried out in the City, he reminded his audience that Wren, engineer though he was as well as architect, never contemplated the possibility of tube railways, therefore thought should be given with sympathy and reverence to the effect on St. Paul's Cathedral when speculators were preparing for further burrowings. Prof. James A. Ewing, F.R.S., proposed "Applied Science," and, in acknowledging this toast, Dr. R. T. Glazebrook, F.R.S., pleaded for a wider application of applied science to trade and industry. The next toast, that of "The Senior Institution," was proposed by Mr. Sidney H. Wells, Wh.Sc., and responded to by Mr. Charles Hawksley, M.I.C.E., and Mr. Alexander Siemens, M.I.C.E. Then Lord Reay, G.C.S.I., G.C.I.E., proposed "The Junior Institution of Engineers" in flattering language, remarking that the members had built up an institution which took a foremost place among the learned societies of the country. The Empire had been largely developed by members of the profession, and a great responsibility rested on the institution to maintain the reputation English engineers had gained in all parts of the world. This was acknowledged by Mr. Samuel Cutler, jun., M.I.Mech.E.

# LEGAL INTELLIGENCE.

## BRIGHTON CORPORATION'S APPEAL.

The appeal of the Corporation in the action brought by Macartney, McElroy, and Co. came before the Court of Appeal on Friday last. The case originally came before Mr. Justice Grantham, and was reported in our issue of May 27 of last year.

**Mr. Moulton, K.C.**, explained that the Corporation in 1900 determined to lay down and work tramways within the borough, and they accepted in 1901 the tender sent in by the plaintiffs, who were contractors. As to the majority of the work there was no dispute, but in one of the sections, which was to be wood-paved, the plaintiffs under the contract were to receive 12s. 7d. per square yard. The contract said nothing about a separate charge for excavating the metal off the road and laying the surface with cement, and his submission would be that as this part of the work must be done before the wood paving could be put down it was understood by all parties that the agreed sum per yard covered this initial expense. The work was finished, and the contractors claimed over and above the sum of 12s. 7d. per square yard 7s. 2d. for preparing the road. The Corporation said they had no power to pay that sum because it was not in the sealed contract, even if, which they denied, the plaintiffs were entitled to make an extra charge under this head. The plaintiffs thereupon brought an action claiming payment at the rate of 7s. 2d. per square yard for getting the road prepared for the wood paving, and they asked, if it were necessary, that the contract should in this respect be rectified. The jury held that the plaintiffs were entitled to this extra charge, which it was said worked out at £14,621, but on the application of the Corporation judgment was postponed until the point of law on which the appeal was based had been argued before Mr. Justice Grantham. After hearing argument the judge made some strong remarks to the effect that the technical defence raised by the Corporation was one that they ought in fairness never to have raised, because it was clear that the plaintiffs, who had done the work, were entitled to be paid. In his opinion the contract did not set forth the intention of the parties, and should be rectified, and he accordingly entered judgment for the amount that should be found due to the plaintiffs on their claim with costs. Counsel proceeded to argue the case on behalf of the Corporation, and submitted that the evidence was that the contract expressed the real agreement.

**Lord Justice Mathew:** There I am against you.

**Mr. Moulton** said he hoped to convince his Lordship from the evidence that his submission was correct.

At this point the case was adjourned until Wednesday, when it was further adjourned.

## TRAMLINES AND MOTOR OMNIBUSES.

In the King's Bench Division on Monday, before Mr. Justice Warrington, Tillings, Limited, sued Dick, Kerr, and Co., the contractors for the electrification of the London County Council's southern system, to recover damages for injuries alleged to have been caused to plaintiffs' 'buses by raised tramrails temporarily laid on the roads by

Digitized by Google

defendants in South London while the conversion was being effected. Defendants pleaded statutory powers, but plaintiffs contended that defendants, being independent contractors, were not protected by statute, and if they were they had been negligent in carrying out their statutory powers. Plaintiffs claimed damages in respect of 69 injuries, and in substance their case was that defendants had created a public nuisance without statutory authority. Defendants denied any negligence, and said they had only done what was reasonably necessary to promote the traffic.

After considerable legal argument, **His Lordship** said that as the case was one of some public importance he would take time to consider the matter.

### TELEPHONE SERVICE.

At Tunbridge Wells County Court last week, before his Honour Judge Emden, the National Telephone Company sought to recover from Mr. Ernest Brooker the sum of £4. 5s. 4d. for the use of telephone and party-line fees.

**Sidney Jared Smith**, the National Telephone Company's manager at Maidstone, said he signed an agreement with defendant for a telephone service connection in 1903. The defendant paid his first instalment for use of service in June, 1903. After that defendant became in arrears to the amount of 12s. 8d. in January, 1904, and was disconnected in February, 1904, due notice being given, as defendant had failed to comply with the agreement. He (the manager) had received no letters of complaint from defendant as to any defects in the service.

On behalf of the defendant, it was urged that there had been a defective service. The company had not supplied an automatic box, and there were many cases where the subscriber could not ring up in time in need.

On the part of the company, it was strongly affirmed that there had been no defective service.

After evidence had been tendered on both sides, a lengthy argument ensued as to whether the disconnection of the service by the company terminated a contract between them and customers.

**His Honour** thought that even if no defective service of telephones had been proved, the company, by disconnecting the defendant's service in February, had thus terminated the contract, consequently the claim would be dismissed.

**Mr. Barton**, on behalf of the company, asked for leave to appeal, but **His Honour** declined to grant this unless the company paid the costs.

**Mr. Barton** said he would consult the company, and at the next Court renew the application.

**His Honour** agreed to consider the question of appeal at the March Court, but said he certainly could not allow the company's present claim against Brooker for reasons he had named. The question of costs would be considered when the application for leave to appeal was renewed.

### TRAMWAY FATALITY.

An action was instituted by Mrs. Jane Pollock against the Glasgow Corporation for £1,000 damages in respect of the death of her husband. Deceased was in the act of descending from the top deck of an electric car at Cleland-street, Glasgow, when, it was averred, the car was started forward and he was thrown to the ground, sustaining injuries which led to his death three weeks later. The defenders denied fault, and pleaded contributory negligence, but the matter has been settled by payment of £150.

## COMPANIES' MEETINGS AND REPORTS.

### WATERLOO AND CITY RAILWAY.

The half-yearly general meeting of this Company was held on the 9th inst. at Waterloo Station, Sir Charles Scotter presiding. Particulars of the report were given in our issue of the 3rd inst.

The **Chairman** remarked that the improved dividend had been brought about not only by increased receipts, but also by decreased expenditure. They were proposing that the Company should supply the electric current for lighting Waterloo Station, and whatever margin of profit there was in connection with the work would be so much to the good of their little company. The Company had carried nearly 16,000 more daily passengers, and the season-ticket holders at the end of the year had increased by more than 200. The progress was slow but sure, and so long as it went on there was no question that in course of time their little dividend would also grow.

The advisability of starting a Sunday service having been alluded to by some of the shareholders, the **Chairman**, in reply, intimated that he was disposed to favour such a course, and the matter would be considered at the next Board meeting. The question of fares had often been discussed by the directors, and they thought that they came to the best decision in the interests of the Company in fixing the fares as they were at present—2d. for the single journey and 3d. return. He certainly would not like to face the question of advancing the fares at the present time. Probably the Baker-street and Waterloo Railway would be opened at the end of the summer, and it would no doubt be an element of increased traffic for their own line.

The report was adopted unanimously.

### CENTRAL LONDON RAILWAY.

The nineteenth ordinary general meeting of this Company was held at the Holborn Restaurant on the 8th inst., under the presidency of Sir Henry Oakley (chairman of the Company).

**Sir Henry** reviewed at length the report and accounts for the half-year (of which we gave particulars in our issue of the 3rd inst.). He then outlined the Company's Bill for completing the circular route, which the directors proposed should be brought forward again. The Great Western Railway have designed a short line to the Central London Company's terminus at Shepherd's Bush so as to provide direct connection. It is probable that the Charing Cross, Euston, and Hampstead and the Baker-street and Waterloo Railways, who will have stations in proximity to those of the Central London Company, will agree to the construction of connecting subways, with through booking, each company conveying the passengers of the other upon a reciprocal basis.

The report was adopted, and a subsequent meeting the Company's Bill was unanimously approved.

The retiring directors—namely, Sir Henry Oakley, Lord Knollys, and the Hon. A. H. Mills—were re-elected.

### LIVERPOOL OVERHEAD RAILWAY.

The half-yearly meeting of this Company was held on Tuesday, Sir William Forwood presiding. Particulars of the report appeared in our issue of the 3rd inst.

The **Chairman**, in proposing the adoption of the report and accounts, said that the decreased earnings were due to the reductions they had made in fares, particularly to working-men. Feeling the competition of the Lancashire and Yorkshire Railway at the North-end very keenly, they had endeavoured to win back the working-men by giving them sectional 2d. return fares, and the net result had been that they had carried 40,000 more passengers, at a profit of £99, equal to ·59d. per passenger, but if they had had the same increase of passengers under the old rate they would have shown an increase of £150. They had also tried a 2d. return ticket from the Dingle. In two months they lost £16—that was, they received that amount less than they would have done under their old rate. They were still working the reduced rate. Differential fares would be introduced as soon as they made their connection with the Lancashire and Yorkshire Railway, and the question of contract tickets would be again considered when they had made their working connection with that railway. The Liverpool tramway system had gradually extended until it now competed with them at many points. The directors had endeavoured to combat all the various difficulties which confronted them by accelerating the speed of their trains, by reducing the fares charged to working-men, and by establishing a tramway system to Waterloo and Crosby; but these had not done all that they hoped, though they had helped to maintain their traffic. They were anticipating considerable assistance from their through traffic arrangements with the Lancashire and Yorkshire Railway. He could assure them that the line was well and economically worked. In reply to questions, the chairman stated that in the opinion of the directors to reduce their fares to 1d. would be disastrous to the line. The report was unanimously adopted, and the retiring directors re elected.

### NORTH METROPOLITAN TRAMWAYS.

The report for the half-year ended Dec. 31 last, to be submitted to the meeting on the 22nd inst., states that the gross receipts for the period amount to £319,275 and the total expenditure amounts to £301,517, leaving as net profit £17,757. This sum, together with £222 brought forward from the last account and the amount received from the Metropolitan Electric Tramways, Limited, for debenture interest, is £20,605, and the sum available for division, after providing for debenture interest, is £17,980. It is proposed to appropriate £17,747 to payment of a dividend at the rate of 4 per cent. per annum on the ordinary shares. The balance of £232 will be carried forward. The number of passengers carried during the half-year was 66,372,192, a decrease of 2,082,478, and the receipts therefrom £310,858, a decline of £10 918. For the whole of 1904 the number of passengers carried was 130,673,957, a decrease of 8,482,628, and the receipts therefrom £611,712, a decline of £40,457. The sum of £18,156 has been charged against revenue for maintenance of the permanent way. Referring to the agreement with the West Ham Corporation for the purchase of the Company's lines and depôts within the borough, which was submitted to and approved by the shareholders on Feb. 11, 1903, the purchase of the lines was carried into effect on June 30 of that year, and the directors report that the price to be paid for the depôts has now been agreed with the Corporation at £63,000, and that the sale will be completed at an early date. The negotiations with the Leyton Council have not yet been concluded.

### BAKER STREET AND WATERLOO RAILWAY.

The report states that the capital expenditure during the past half-year amounted to £173,133. For the current half-year the estimated expenditure is £600,000. Satisfactory progress is being made with the works. Between the Elephant and Castle and Baker-street the running tunnels have been driven throughout. All the station tunnels are through except the down tunnel at the Elephant and Castle. The platforms are being constructed, and the underground tiling and other work of completion is being proceeded with. The station buildings have been commenced. Half the permanent way has been laid. Good progress has also been made on the Paddington section. Arrangements for the interchange subway with the Marylebone Station of the Great Central Company have been made. Arrangements for ventilation, secondary lighting, and signalling are well advanced, and the high-tension cables to the sub-stations on this Company's line are now three-quarters complete. Eighteen trains of six cars each, also trucks, motors, and controlling apparatus, are all on order, and delivery of this rolling-stock should commence in May. The Company is promoting a Bill in

Digitized by Google

Parliament to obtain power to make certain alterations in the subways at Trafalgar-square and the Elephant and Castle, to extend the time for the completion of the works and purchase of lands, also for power to issue debenture-stock certificates to bearer.

## NORTHAMPTON ELECTRIC LIGHT AND POWER.

The report for 1904, to be presented at a meeting to-morrow, states that the lamps and motors connected during the year were 6,576 (motors being reckoned in the equivalent of 8-c.p. lamps), making a total of 47 431 8-c.p. The motors, reckoned in horse-power, have increased from 251½ to 351½. Of these, 210 h.p. are hired out by the Company. The separate consumers have increased from 704 to 801. Distributing mains have been laid to the extent of 1 mile 1,262 yards, bringing the total up to 14 miles 1,575 yards. Additional feeder mains have also been laid amounting to 1 mile 1,631 yards. The extension to Dallington has been fully justified by the results. In the early part of the year the nominal share capital was increased from £50,000 to £100,000. There are now two classes of shares only—namely, ordinary and 5 per cent. cumulative preference—the founders' shares having been surrendered. As soon as there is a sufficiency of spare revenue, the extra dividends, or compensation, will be paid, but this can hardly be fully effectuated during the present year. An important purchase of land was made during the year, with a view to future needs. Substantial additions have been made to the plant. The provisional order extending the area of supply to the whole of the county borough, as now constituted, and to various parishes has been confirmed by Act of Parliament. The Town Council made an offer to purchase the business, but the terms were considered inadequate. A further sum of £1,750 is now added to the depreciation fund, besides £50 written off motors. A certain amount of old plant has been sold, and the loss has been written off. The accounts show £1,746 available for dividends. It is proposed to pay a dividend at the rate of 5½ per cent. per annum for the half-year on the ordinary shares, making, with the interim dividend, 5 per cent. for the year. This will leave £316 to be carried forward. The directors are now prepared to allot £1,170 5 per cent. preference shares at 1s. 6d. premium per share, also 5,000 ordinary shares, at a premium, by way of tender. The highest tenders will have the first consideration, but regard will also be had to the amount of the applicant's present holding. Members of the company and debenture-holders are at liberty to apply. The premium will then be payable, and 10s. in the £ on the shares allotted; the remainder by equal instalments on June 30 and Sept. 30.

## KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING.

The report for 1904, to be presented at the meeting on the 23rd inst., states that during the year the number of houses and shops connected with the system has increased from 3,210 to 3,451, while the number of lamps, calculated on the usual basis of 8-c.p., has increased from 280,133 to 303,048. The renewal account now stands at £55,932 an increase of £5,502. After providing for the amount placed to renewal account, writing £3,000 off cost of purchase of Kensington Court Company, Limited, in the capital account, and paying the dividends on the 6 per cent. first preference shares to June 30, 1904, on the 5 per cent. second preference shares to Sept. 30, 1904, and an interim dividend at the rate of 10 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to credit of the net revenue account for 1904 is £18,659. Of this sum, £1,500 has been appropriated to the payment of the first preference dividend to the end of the year and £625 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date. It is proposed to pay out of the balance of £16,534 a further dividend on the ordinary shares at the rate of 10 per cent. per annum for the past half-year and a bonus of 2 per cent. for the year, making, with the interim dividend paid on Aug. 1, 12 per cent. for the year. This will leave a balance of £9,184 to be carried forward. During the year substantial reductions have been made in the charge for supply, representing a considerable saving to the consumers.

## CHARING CROSS AND STRAND ELECTRICITY SUPPLY.

The report for the year ended Dec. 31, 1904, to be submitted at the meeting on the 22nd inst., states that a new sub-station has been built in the Green Park, under agreement with the Office of Works, for the purpose of supplying the public lamps in the Mall and parks, the Queen Victoria Memorial, and for other purposes. The lamps added during the past year have been 73,722 (8 c.p.), an increase of nearly 25 per cent. on the highest number previously obtained in the West-end areas in any year. The total number now being supplied in the West-end is 409,663. The total mains now laid amount to 325 miles. The regulations of the London County Council require all theatres to be furnished with supplies from two separate sources. The dual or alternative supply which was provided by the directors, under the advice of their engineer, has now been approved as complying with these regulations. The revenue from sales of current for 1904 amounted to £122,877, as against £110,083 in 1903. The balance of net revenue is £55,942, and it is proposed to pay a dividend on the ordinary shares of 3 per cent. for the year, carrying forward £10,223. With reference to the City undertaking, the erection of the first half of the generating station at Bow, which will hold plant of sufficient capacity to supply the equivalent of 800,000 8-c.p. lamps connected, is now completed, and contains plant to supply 600,000 lamps. Further plant of the capacity of 200,000 lamps will shortly be delivered. The four sub-station buildings in the city are now completed, and contain large storage batteries and plant of sufficient capacity to supply 450,000 8-c.p. lamps connected. There is ample space to more than treble this capacity with practically no additional expenditure on buildings. Mains have been laid in all the principal and most of the secondary streets in the City. These are of sufficient capacity to supply upwards of 500,000 8-c.p. lamps. Spare ways have also been provided into which extra mains, capable of increasing the supply to 1,000,000 lamps, can be drawn. There are 265 miles of mains now laid. There have been added during the year the equivalent of 58,968 8-c.p. lamps, bringing up the total now supplied to 301,081. The gross revenue from sales of current during the year amounted to £78,431, or £22,394 in excess of 1903. The net revenue account shows a profit of £15,670, which has been applied towards the payment of the 4½ per cent. preference share dividends to Dec. 31, 1904, and the balance of such dividends has been provided under the guarantee of the West-end undertakings. The directors have thought it advisable, to enable the Corporation to comply with the increasing demand for electrical energy for railway, tramway, and other motive power purposes, to apply to Parliament for an extension of the areas of supply and further powers, and the Bill for conferring such powers was approved by the resolutions passed at the extraordinary general meeting held on Feb. 3, 1905. These resolutions will be submitted for confirmation at the extraordinary general meeting convened to take place immediately after the annual general meeting. At the same meeting the proposed change in the Corporation's name will be submitted for confirmation. The Charing Cross and City Electric Company, Limited, was formed under the authority of resolutions of this Company for the purpose of contracting for and carrying out the works in the city of London. These works are now practically completed, and the directors are proposing to close all accounts between the two companies. Agreements for this purpose have been prepared, and will be submitted to the shareholders for confirmation. Copies of these agreements will be open for inspection by any shareholder at the offices of the Company for two days prior to the date fixed for the meeting.

## WESTMINSTER ELECTRIC SUPPLY.

The report for 1904, to be submitted at the meeting on the 22nd inst., states that the supply of current, which on Dec. 31, 1903, was provided for the equivalent of 662,129 lamps of 8 c.p., has increased to the equivalent of 711,679 lamps, and applications for supply continue to come in at a satisfactory rate. The new transformer station at Duke-street-gardens is not yet completed, but arrangements having been made for part of the space to be available for the engineers, the first section of plant has been erected and came into use on Nov. 25 last. The result of the year's working justifies the directors in once more recommending an increased dividend—namely, 14 per cent. There being a growing demand for current at a low price, the directors consider that any additional profits should for the present be devoted to the development of the Company's business by the reduction in the rates of charge. A reduced scale of charges came into force on Jan. 1, which will naturally affect the receipts for the current year, and it is, therefore, necessary to carry forward a sum of money sufficient to meet the temporary diminution of profits which may result from the reduction in price. After allowing for depreciation, sinking fund, and other charges, the net balance is £56,328. Out of this the Board recommend the payment of a dividend at the rate of 15 per cent. per annum for the past half-year, carrying forward a balance of £13,798.

## NEW COMPANIES REGISTERED.

**Lowden Electric Lamp Company, Limited (83,470).**—Capital, £3,000. Object: to acquire and take over, as a going concern, the business carried on at Watford, Hertfordshire, as the Lowden Electric Lamp Works. Registered office: Granville House, Arundel-street, Strand, W.C.

**Electric Power Development Company.** — Capital, £50,000. Object: to promote a Bill in Parliament to consolidate the sources of electricity supply in Greater London, and afford facilities to borough councils and electric lighting companies to purchase current wholesale, at prices varying from ¾d. to 1½d. per unit. In many cases this arrangement would at once considerably enhance the profits of the distributing authority, as the present average cost of the production is much higher than 1½d. The Bill provides for a share capital of five millions.

**Motorcar Company (1905), Limited.**—Capital, £2,000. Object: to promote and protect the interests of the professions, trades, and industries connected with the design, improvement, manufacture, and supply of motor-carriages, vehicles, cycles, tramcars, etc.

**Bohm Lens Lamp Company, Limited (83,466).**—Capital, £4,000. Object: to acquire and carry on the business at 104 and 105, Great Russell-street, W.C., as Bohm Lens Lamp Company, as lamp manufacturers, glass-blowers, electricians, suppliers of electricity, etc. Registered office: 104, Great Russell-street, Bloomsbury, W.C.

### Liens Registered.

**Bridgwater and District Electric Supply and Traction Company, Limited.**—Particulars of £12,000 debentures, created by resolution of Nov. 11, 1903, have been filed, pursuant to Section 14 (4) of the Companies Act, 1900. Property charged—the company's undertaking and property, present and future, including uncalled capital. No trustees.

### Discharge Registered.

**Kalgoorlie Electric Power and Lighting Corporation, Limited, London, E.C.**—Discharge registered Feb. 3 of mortgage dated July 10, 1902, for a sum not exceeding £10,000.

Digitized by Google

## PERSONAL.

Mr. Thomas Browett, M.I.M.E., M.I.E.E., has been appointed manager of the Diesel Engine Company, Limited, 179, Queen Victoria-street, London, E.C.

The Wakefield City Council have appointed Mr. H. Nevill, first electrical engineer, to the position of city electrical engineer at a salary of £300 per annum, with increments of £25 per year to £400.

The Battersea Borough Council have selected three candidates for the post of borough electrical engineer, the appointment for which is to be made next Wednesday.

Mr. H. H. Oxley, of the Lincoln electricity works, has been appointed charge engineer at the Lynn electricity works at a salary of £65 per annum.

## APPOINTMENTS VACANT.

**Switch-Room Superintendent,** Glasgow Telephone Department. See advertisement in last issue.

**Junior Shift Engineer,** Dover. Salary £80 per annum.

**Meter Reader,** Lynn.

**Tramways Manager,** Ayr Corporation. Salary £200 per annum. Applications by 18th inst.

**Assistant Electrical Engineer,** Whitby Urban District Council. Salary £104, rising £4 annually to £120 per annum.

**Electrical Engineer** Great Western Railway. Salary £600 per annum. Applications by Feb. 27. See advertisement.

**Mains Superintendent,** Carlisle, Salary £120 per annum. Applications to Corporation's Electricity Works by Feb. 28.

**Inspector of Telephones,** Brighton Corporation. Applications by March 4.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Oporto.**—The Municipal Authorities require tenders for lease of their electric tramways. Tenders by March 15.

**Swindon.**—The Corporation invite tenders for the supply, delivery, and erection of switch panels, etc. Tenders by Feb. 21.

**Dublin.**—The Corporation invite tenders for the supply of arc lamp carbons to their electricity undertaking. Tenders by Feb. 23.

**Ghent.**—The Municipality require tenders for 15 electric cranes for the harbour works. Provisional estimate, £1,200. Tenders by Feb. 20.

**Sunderland.**—The Corporation invite tenders for the supply of four 250-kw. synchronous three-phase motor-generators. Tenders by 24th inst.

**Fulham.**—The Borough Council invite tenders for the supply of electrical stores for year ending March 31, 1906. Tenders by 4 p.m. on March 15.

**King's Lynn.**—The Corporation invite tenders for one 200-kw. steam dynamo, condenser, steam and other pipes. Tenders by 28th inst. See advertisement.

**Hull.**—The Electric Lighting Committee invite tenders for the supply, etc., of mains and cables for 12 months. Tenders by 12 noon on March 1. See advertisement.

**Stoke Newington.**—The Council invite tenders for the supply, delivery, and erection of sub-station plant and mains. Tenders by 4 p.m. on March 8. See advertisement.

**Lirla.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Battersea.**—The Council require tenders for the supply for one year from March 31 next of electricity meters, joint-boxes, carbons, coal, and oil stoves. Tenders by Feb. 27.

**Shoreditch.**—The Council invite tenders for their yearly contracts in the electricity works and other departments. Tenders by March 14. Full particulars in our advertisement columns.

**Madrid.**—The Department of Agriculture, etc., invite tenders for installation and working for 60 years of an extension of the electric tramways in the north of the town. Tenders by Feb. 25.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Lowestoft.**—The Corporation invite tenders for one water-tube boiler with superheater, brickwork settings, and accessories, together with the necessary pipework. Tenders by March 9. See advertisement.

**Dax (France).**—Tenders are required for a concession to erect and work electric lighting of the town for 35 years. Particulars may be obtained from the Secretary to the Municipality of Dax, Province of Landes, France. Tenders by March 6.

**Rathmines and Rathgar.**—The Urban District Council invite tenders for the supply of coal for electric lighting purposes (about 2,000 tons), cables, etc., arc lamp carbons, and general stores. Tenders by Feb. 20. See advertisement in last issue.

**Kilkenny.**—The Committee of the District Lunatic Asylum invite tenders for fixing in the asylum an electric installation of tell-tales, consisting of 18 stations, and one recording tell-tale clock. Tenders must be delivered at Asylum before 4 p.m. on Feb. 20. Mr. Joseph Brennan, clerk.

**Madrid.**—Der Compania Electrica Madrilena de Traccion propose to extend their electric tramways from the Barquillo-street to Olivide-place. The concession for the works will be dealt with by the Public Works Department, Madrid, April 2. Tenderers for same must deposit a guarantee of £96.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Great Western Railway.**—The directors invite tenders for the supply, delivery, and erection of plant in connection with their electricity generating station at Park Royal and proposed sub-stations and distributing centres at various places. Tenders by March 13. See advertisement in last issue.

**Salford.**—The Electricity Committee invite tenders for the supply of the following cables: 1,800 yards of 0·75 square inch lead-covered and paper-insulated cable, 1,200 yards of 1·2 square inch lead-covered and paper-insulated cable, and 1,760 yards of $^{7}/_{16}$ high-tension concentric cable. Tenders by Feb. 18.

**Stockport.**—The Corporation invite tenders for supply and delivery of points, crossings, and special work in connection with the tramways. Specification, conditions, form of tender, and all information may be obtained on application to Mr. John Atkinson, A.M.I.C.E., borough surveyor, Stockport. Tenders by Feb. 20.

**Wimbledon.**—The Urban District Council invite tenders for the supply of (3) engine-room stores, (4) cables, (5) joint-boxes and jointing materials, (6) transformers, (7) meters, (8) oils, (9) incandescent electric lamps, carbons, and accessories, (10) iron castings. Tenders by March 4. See advertisement in last issue.

**Newport (Mon.).**—The Electricity and Tramways Committee invite tenders for 300-kw. continuous-current high-speed tramway generator (engines of enclosed type), 200-kw. continuous-current high-speed steam balancer (engines of enclosed type), boiler, switchboard, stores, etc. Tenders by March 6. See advertisement.

**Islington.**—The Council invite tenders for (Section A) meters, (B) time switches, (C) earthenware pipes, (D) carbons, (E) incandescent lamps, (F) terminal boxes, (G) arc lamp globes, (H) oils and lubricants, (I) waste, etc., (J) belting, (K) rubber and asbestos, (L) engineers' stores, sundries. Tenders by Feb. 23. See advertisement in last issue.

**Batley.**—The Batley Co operative Society, Limited, Commercial-street, Batley, invite tenders for wiring and fittings in connection with the electric light installation at the new central stores. Copies of the specifications can be had on receipt of 10s. at the offices of Mr. Harry B. Buckley, architect, 85, Commercial street, Batley, up to Feb. 16, and tenders are to be delivered by 4 p.m. on Feb. 20.

**East Ham.**—The Borough Council invite tenders for supply and delivery of five double-deck roof-covered tramcars, complete with electrical equipment. Full particulars, form of tender, and specification may be obtained on payment of £1. 1s. (which will be returned upon receipt of a bona fide tender) from Mr. W. C. Ullmann, M.I E.E., M.I.M.E., Nelson-street, East Ham. Tenders by Feb. 21.

**Manchester.**—The Electricity Committee invite tenders for the supply, delivery, and erection of the following at Dickinson-street station and sub-stations: (a) motor-generators, (b) five-wire balancers. Further information will be given by Mr. S. L. Pearce, chief engineer, Electricity Works, Dickinson-street, Manchester. Tenders to the chairman of the Electricity Committee, Town Hall, by 10 a.m. on Feb. 21.

**Fulham.**—The Borough Council invite tenders for the supply and erection of (A) condensing plant; (B) boilers; (C) economisers; (D) stokers. Specification, drawings, and form of tender may be obtained from the borough electrical and consulting engineer, Mr. Arthur J. Fuller, on payment of a deposit of £1. 1s., which will be returned on receipt of a bona fide tender. Tender to the Town Clerk by 12 noon on Feb. 22.

**Erith (Kent).**—The Urban District Council invite tenders for the execution of all work required under the Council's assisted wiring scheme for period ending March 31, 1906. Specifications and forms of tender may be obtained from Mr. Geo. E. Heath, electrical engineer, from whom any further information desired can be obtained on payment of a deposit of £1. 1s. for each copy required, such deposit being returnable on receipt of a bona fide tender. Tenders by Feb. 20.

**Shanghai.**—The Municipal Council invite tenders for the construction and operation of about 24 miles of electric tramways on the trolley system in the streets of the Settlement of Shanghai; alternative proposals are desired for the single-trolley and double-trolley lines. A pro forma contract is open to inspection by tenderers, and copies will be supplied to applicants by the Council's agents, Messrs. John Pook and Co., 63, Leadenhall-street, E.C. Tenders by March 31, 1905.

**South Shields.**—The Electricity Supply Department invite tenders for the supply, delivery, and erection of the following plant: (Contract No. 67) one multitubular marine-type boiler, with chimney and mountings; (68) two medium-speed open-type vertical engines for two 550-kw. direct-current traction generators; (69) two 550-kw. direct-current traction generators; (70) traction switchboard; tramways department—(Contract No. 4) electric tramcars, complete with "Brill" trucks, for the Corporation. Copies of specifications, conditions, form of tender, also form of contract, can now be obtained from Mr. J. H. Cawthra, M.I.E.E., borough electrical engineer, South Shields, on payment of £2. 2s. for each contract, which sum will be returned on receipt of a bona fide tender for each contract. Tenders to Mr. J. Moore Hayton, town clerk, Court-buildings, South Shields, by noon on March 13.

**Johannesburg.**—The Municipal Council are prepared to receive tenders for 100 electric tramcars, two electric water-cars, one five-ton travelling crane, one electric car traverser, and various workshop tools, including erection at Johannesburg, to Specification No. 10 of their consulting engineers, Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W. Copies of the specification may be seen on and after Jan. 7 at the Council Offices, Johannesburg, and at the Consult-

Digitized by Google

ing Engineers' Offices in London, and may be obtained on payment of five guineas, which will be returned on receipt of a bona fide tender. Duplicate copies of the specification may be bought for 10s. each (not returnable). Tenders must be addressed to Messrs. Mordey and Dawbarn, 82, Victoria-street, London, S.W., and must be received by them not later than March 6. The Council will not be responsible for any expenses incurred in tendering.

**South Shields.**—The Corporation invite tenders for the execution of the works and the supply of plant in connection with the laying of proposed electric overhead tramways in the streets of the borough: (Part 1) permanent way and construction of track; (2) copper rail bonds, bonding of tramrails; (3) conduits, cables, and overhead equipment. Specification, etc., can be obtained from Mr. J. Moore Hayton, town clerk, on payment of £5. 5s. for each of Parts (1) and (3), and £2. 2s. for Part (2), which sum will be returned on receipt of a bona fide tender for each part. General and detailed plans of the proposed works can be seen as regards Part (1) at the office of Mr. S. E. Burgess, M.I.C.E., borough engineer, Chapter-row, and as regards Parts (2) and (3) at the office of Mr. J. H. Cawthra, M.I.E.E., the borough electrical engineer, West Holborn, South Shields. Tenders to the Town Clerk, Court-buildings, South Shields, by Feb. 20.

## RESULTS OF TENDERS.

**Shildon.**—Messrs. Clark and Co. have obtained the contract for the electrification of Shildon.

**Keighley.**—The Corporation have accepted the tender of the Brush Electrical Engineering Company for two tramcars at £1,080.

**Stockport.**—The Tramways Committee have accepted the tender of Messrs. Blackwell and Co., London, at £4,343. 11s. 3d., for the overhead equipment and copper bonds, and also for the 10 cars required for the Hazel Grove electric tramway route.

**Gravesend.**—The Town Council have accepted the tender of the Western Electric Company for the necessary concrete drawing-in pits with suitable frames and covers, drawing in the cable, the station and boxes, and connecting to their switchboards, at £48. 9s., and that of Messrs. Cowans, Limited, for the switchboard, at £106. 10s.

**Leftwich.**—Messrs. R J. Nicholson and Co., of Manchester, have secured the contract for the electric light installation at the isolation hospital, Leftwich, near Northwich, from the Northwich Rural, Northwich, Middlewich, and Winsford Committee. In addition to the fitting of the various blocks, the contract includes a distribution system of underground mains.

**Diesel Engines.**—The Diesel Engine Company, Limited, 179, Queen Victoria-street, London, E.C., report the following orders: Peruvian Cotton Manufacturing Company, London, 400 b.h.p.; Caleb, Shadbolt, and Co., Uxbridge, 160 b.h.p.; Electric Construction Company, Limited, Wolverhampton, 20 b.h.p.; Linde British Refrigeration Company, Limited, London, 40 b.h.p.

**St. Marylebone.**—The tender of the Electrical Power Storage Company for the supply and erection of the storage battery for the sum of £2,418 was recommended for acceptance last night; and that of C. A. Parsons and Co., of Newcastle-on-Tyne, for the construction of the stairways, flooring, and grating of the engine-room at the new generating station, according to the specification prepared by the engineer, for £2,952.

**Erith.**—The Electricity and Tramways Committee have recommended the following tenders for acceptance: Brush Electrical Engineering Company, overhead equipment, etc., £4,217; Callender's Cable and Construction Company, underground feeder cables, etc., £2 590. 4s., and £51. 16s. for additional two years' maintenance; British Westinghouse Company, rotary converters, etc., £1,545. 5s.; General Electric Company, high and low tension switchboards, etc., £1,169.

**Bradford.**—The Corporation have accepted the following tenders for miscellaneous stores required by the Tramway Department: J. Rushforth and Son, Bradford, timber; H. Barrett and Son, Bradford, iron and steel; Baxendale and Co., Manchester, varnishes; S. Mason, Birmingham, dry colours; R. R. Minton and Co., Bradford, paints and white lead; Stephenson Bros., Bradford, painters' sundries; General Electric Company, Manchester, electrical accessories; Bradford Incorporated Institution for the Blind, cleaning brushes; J. S. Heap and Sons, Bradford, paint-brushes; A. W. Fairless and Co., Bradford, glass; S. Miller, Bradford, oils, grease, etc.; Veritys, Limited, Manchester, lamp fittings; Thornton and Crebbin, Bradford, iron castings; T. Gameson, Walsall, malleable-iron castings; Jonas Wells, Keighley, steel castings; W. F. Dennis and Co., London, cables and wires; Wood and Saberton, Bradford, bolts, nuts, and washers, wood handles and shafts, galvanised iron and tinware, screws, nails, and rivets, and hard tools; S. W. Whaley and Co., Bradford, rope, twine, paper, etc.; Taylor and Parsons, Bradford, lead, tin, etc.; J. W. Rowlands and Co., Birkenhead, pinion wheels; London Transfer Depôt, Snow-hill, London, transfers; S. Dixon and Sons, Leeds, trolley poles; W. Vaux, Bradford, files.

# BUSINESS NOTES.

## TRACTION.

**Keighley.**—The Stockbridge route was opened on Friday last.

**Newark.**—The Light Railway Commissioners have sanctioned the light railway scheme.

**Stalybridge, Hyde, etc.**—The Joint Board have decided to adopt ½d. fares on all routes.

**Halifax.**—The extension from Sowerby Bridge to the Triangle was opened on Friday last.

**Rideford and Hartland.**—A light railway scheme was approved at a meeting of the inhabitants.

**Royton.**—A commencement has been made with the construction of the electric line to Crompton.

**Accrington.**—The Rawtenstall Council have decided to present a petition against the Corporation's Tramway Bill.

**Falkirk.**—It is reported that the company will make an early commencement with the construction of their system.

**Birmingham.**—The Small Heath route, leased to the company, was due to be inspected yesterday, and to be opened to the public if satisfactory.

**Blagdon-Pensford.**—The projected light railway between these Gloucestershire towns is receiving enthusiastic support from the inhabitants.

**Rochdale.**—The Whitworth Urban District Council have decided to ask the Corporation on what terms the latter will run a line to Whitworth.

**Argentina.**—It is reported that the tramway concession granted to Messrs. Otto Bemberg and Co. for an electric line between Buenos Ayres and Conchitas has been transferred to an Argentine company.

**West Hartlepool.**—The differences between the Corporation and the company are likely to be disposed of amicably, and the summonses taken out against the latter have accordingly been adjourned for a month.

**Loughborough.**—The Town Council having received a communication from a local authority on the subject of a municipal tramway service, have decided to reply that it is a matter for private enterprise.

**West Cumberland.**—Referring to the note in our last week's issue, it was reported at last week's meeting of the Whitehaven Town Council that the company have now agreed to commence the work within one year.

**Bath.**—The Rural District Council having been approached by the tramway company for consent to an extension to Newton St. Loe, which the County Council are opposing, the District Council decided to remain neutral.

**Swindon.**—The Tramways Committee are to consider the question of extensions, particularly to Coate. Some of the councillors favour motor-omnibuses, powers for which Parliament refused to grant the Corporation some time ago.

**Paisley.**—It looks as though the company's proposed extension to Killarchan will not be made at present, as the authority not only insist upon paving works, to which the company are agreeable, but also upon double lines throughout.

**Exeter.**—The Bishop of the diocese headed a deputation to the Corporation last week against the proposed Sunday running. The Corporation decided, however, to adopt the Tramway Committee's report recommending a service from 1.30 to 10.

**South-Eastern and Chatham Railway.**—Having experimented with a steam motor carriage between Ramsgate and Margate, it is reported that the company intend to run a service on this section to compete with the Isle of Thanet Tramways Company.

**Mexborough and Swinton.**—It is reported as probable that terms will shortly be arranged between the company and the Rawmarsh Urban District Council, under which the former will begin the construction of their system before the 31st prox. and complete same within two years.

**Derby.**—The extension from Victoria-street to the Market-place has been completed, and on Saturday morning a satisfactory trial was run. The contract has been completed a week before the time allowed, and had it not been for several interruptions by bad weather the work would have been finished earlier.

**Great Northern, Piccadilly, and Brompton Railway.**—A little complication arose owing to the freehold of the site for this company's station at Piccadilly-circus belonging to the Crown, but conditions have now been agreed, and the London County Council have given their approval to the plan submitted by the company.

**Bristol Tramways and Carriage Co., Limited.**—The gross receipts for the year ending Dec. 31 amount to £259,799, while the working and general expenses and renewals total £168,798, leaving a net revenue of £91,000. It is proposed to pay a final dividend for the half-year at the rate of 9 per cent. per annum, carrying £17,769 to reserve.

**Baker-street and Waterloo Railway.**—The London County Council have conditionally approved the company's plan of the station to be erected in Harewood-avenue, Marylebone. The £500,000 4 per cent. perpetual debenture stock of this company, offered at £96 per cent., was all subscribed and the lists closed on Wednesday, the opening day.

**Glasgow.**—It appears that the Corporation's proposed extension to Partick has fallen through, the latter authority holding out for terms to which Glasgow could not agree. It is reported that, as the result of a further reference to Lord Balfour of Burleigh, the Corporation and the Paisley Company are likely to come to terms in a few days, by which the former will run to Paisley Cross.

**London and South-Western Railway Co.**—At the meeting of this company the Chairman referred to the experiment in electric traction which is to be tried on a portion of the South-Western line between Putney Bridge and Wimbledon, worked by the District Company. All the South-Western Company's trains will be carried over this section by electrical working, and also up to Richmond.

**Croydon.**—On the grounds that the proposed extension of the trams to Upper Norwood cannot be expected to pay working expenses, that the debt of the town is over £2,000,000, and that the rates have risen from 5s. to 7s., a petition has been lodged against the scheme by

Digitized by Google

owners and frontagers. It will be remembered that a *plébiscite* was taken recently, when the proposal was affirmed by a small majority.

**Edinburgh.**—The authorities adjoining Edinburgh have received a communication from the syndicate to which we referred a few weeks ago. It is proposed to construct an electric tramway through the suburbs, and the letter suggests a conference. A sub-committee has resolved to recommend that powers be sought to construct an electric line on the Gilmore-place route, which is at present worked by animal haulage.

**Manchester.**—The Urmston District Council at its meeting on Tuesday adopted a long report on the tramways question, in which the negotiations with the Manchester Tramways Committee were described in full. The District Council have taken the opinion of Mr. Balfour Browne, and it is probable that terms will be agreed between the two councils for constituting the Manchester Corporation the tramway authority for Urmston.

**Walsall.**—The Corporation have adopted the tramway accounts, of which we gave particulars recently. A discussion occurred on the question of depreciation, one councillor stating that if a suitable amount had been placed aside for this purpose the gross profits would have been reduced from £7,932 to £2,932. The general consensus of opinion, however, was that the undertaking had been eminently successful for its initial year.

**Llanelly.**—At a meeting of the Roads Committee last week, it was reported that the tramways were to be transferred from the local company to the Llanelly and District Electric Lighting and Traction Company, subject to the approval of the Board of Trade, and that any objections or representations with respect to such proposed transfer were to be made to the Board of Trade. It was decided to present to the Board a complaint of the conditions of the tramways.

**Tranent.**—The committee recently appointed at a public meeting to act conjointly with the Burgh Commissioners to further the scheme for the extension of the electric tramway system from Levenhall to Tranent held a meeting last Friday, when the deputation appointed to interview the company presented a report. After consideration of the report, it was unanimously agreed to prepare petitions for presentation to the directors in furtherance of the extension scheme.

**Cleveland and Portishead Light Railway.**—In the Chancery Division on Saturday, the matter of the Weston, Clevedon, and Portishead Light Railway Company and the Railway Companies Act, 1867, came before Mr. Justice Farwell as a petition. On the case being called on, counsel said that the matter was practically settled, and he asked that his lordship would direct that the petition should stand over generally. His lordship assented, and made the order accordingly.
